Elected for nine years—(term normally expires in 1948). R. E. Buchanan (U.S.A.), A. J. Kluyver (The Netherlands), E. G. D. Murray (Canada), S. Orla Jensen (Denmark). *Elected for six years*—(term normally expires in 1945). J. Howard Brown (U.S.A.), A. R. Prévôt (France), J. Ramsbottom (Great Britain), Th. Thjötta (Norway). *Elected for three years*—(term normally would have expired in 1942). A. Lwoff (France), R. Renaux (Belgium), A. Sordelli (Argentina), C. Stapp (Germany).

It has been decided to make this announcement in the hope that some plan for taking tentative action on questions of nomenclature can be developed by those members of the Commission who can be reached under war conditions.

While no provision was made in 1939 for the contingencies that have arisen, it is felt that those elected should serve until successors are elected. Professor R. E. Buchanan has been asked to act as Chairman *pro tem* of the Judicial Commission as there is no possibility of securing an election under the rules as adopted.

Bacteriological Nomenclature

DOES THE MEDICAL SHORTAGE AFFECT PUBLIC HEALTH?

On March 29 the Office of War Information, Washington, released a survey of medical care in the United States which showed that between forty and forty-five thousand doctors had entered the armed services, constituting approximately one-third of the doctors in active full-time practice. A review of the situation in some 60 communities in 20 states where shortages of doctors have been reported included areas in farming regions, mushroom towns and larger cities. The following conclusions were reached by the report.

1. Although there are areas critically in need of doctors because of withdrawals for the armed forces—a need frequently increased by expansion of population for war industry—so far the health of the nation as a whole has not been seriously impaired by the doctor shortage. Doctors these days are not only working overtime; they are—most of them—working practically all the time and in total disregard of their own health.

2. The number of communities critically in need of doctors is not great compared with the total number of communities in the United States. Those in need, however, are among those most vital to our war program.

3. In too many cases physicians were recruited for the armed services without sufficient regard for the welfare of the civilian population. There are, however, enough doctors remaining in private practice to give adequate care to the civilian population, provided they can be properly distributed numerically and according to special abilities.

4. The voluntary relocation of physicians from communities where there is an abundance of doctors to areas in acute need of doctors has proved extremely difficult, and has not resulted in a solution of the problem.

5. In some communities local medical groups have resisted attempts to relocate outside doctors in their locality.

6. The situation as a whole is not now out of control, but unless remedial steps are taken soon it will grow progressively worse. More physicians will be recruited for the armed forces and doctors in critical areas—many of them elderly—may succumb to exhaustion from overwork.

7. Luxury medicine, to which some Americans have become accustomed, is out for the duration. We can no longer afford to call

doctors for imaginary ailments, and we must make the best and most efficient use of the medical facilities we have.

8. Medical shortages are not due in all cases to the war, although frequently the war has intensified them. For instance, many rural areas have never had a sufficient number of doctors. It is not the purpose of this report to recommend that long-standing problems be solved in time of war except as they relate to our progress toward victory.

The Office of War Information has announced that the material will be assembled in a booklet and made available to health workers on request.

DENTISTS IN INDUSTRY

What was said to be the first meeting of dentists interested in dental programs in the industrial field was held in Chicago on February 22, under the auspices of the Committee on Economics of the American Dental Association. An organization was formed, the next meeting to be held in Cincinnati next October. The following were elected officers:

Chairman—E. S. Arnold, D.D.S., Traveler's Insurance Company, Hartford, Conn.

Secretary—R. M. Walls, D.D.S., Chairman, Committee on Economics, American Dental Association

Advisory Board—Ernest Goldhorn, D.D.S., Dental Director of the Pullman Standard Car and Manufacturing Corporation; R. C. Dalgleish, D.D.S., Dental Director, Utah State Board of Health; Frank Haughton, D.D.S., Dental Director, Medical Center, Jersey City, N. J.; Hugo M. Kulstad, D.D.S., Member of Council on Dental Health of the American Dental Association and Chairman of Council's Committee on Industrial Dental Programs; L. D. Heacock, D.D.S., Dental Surgeon (R) U. S. Public Health Service, Division of Industrial Hygiene, National Institute of Health; Robert S. Sprau, D.D.S., Dental Adviser, Kentucky State Health Department

Several papers were presented and Dr. Carl Peterson—Secretary of the Council on Industrial Health of the American Medical Association—presented the problems encountered by the medical group when they first entered

the industrial field. Basic objectives for dental programs in war industries were outlined.

OFFICE OF FOREIGN RELIEF AND REHABILITATION OPERATIONS

Herbert H. Lehman, former Governor of New York State and now Director of the Office of Foreign Relief and Rehabilitation Operations of the Department of State, Washington, announced recently the circumstances under which the Advisory Committee on Health and Medical Care had been set up under the Chairmanship of Surgeon General Thomas Parran of the Public Health Service.

The Office of Foreign Relief and Rehabilitation Operations has recognized from the outset the necessity of planning and executing an extensive medical and health program in theaters of relief operations. Almost from the outset of our operations, the several governmental agencies concerned with the various aspects of public health and medical care were asked to provide their assistance. A number of these agencies have been working on these problems in advance of the creation of the Office of Foreign Relief and Rehabilitation Operations.

In establishing this Committee I asked it to undertake the following work:

1. To collect and analyze available information concerning disease prevalence and important health problems in areas which may be reoccupied by our armed forces.

2. To appraise the epidemic and other disease conditions which are likely to be an important part of relief and rehabilitation.

3. To estimate the amount and kinds of essential health and medical supplies and equipment which must be provided.

4. To consider—at least in general terms—the numbers, skills and potential sources of personnel needed to deal with epidemic and other health problems.

5. To consider, in conjunction with appropriate agricultural and other sources of information, the nutritional problems ahead.

6. To advise the Director of Foreign Relief and Rehabilitation upon request concerning other aspects of public health as the occasion requires.

In addition to the Chairman, Dr. Parran, the Committee now includes:

Colonel James S. Simmons U. S. Army; Commander T. J. Carter, U. S. Navy; Dr. Martha Eliot, Children's Bureau; Dr. Alfred Cohn, Board of Economic Warfare; Professor C.-E. A. Winslow, Yale University School of Medicine; Dr. Frank G. Boudreau, Director of the Milbank Memorial Fund; Selskar M. Gunn, Vice-President of the Rockefeller Foundation, and Dr. James A. Crabtree.

Governor Lehman also announced the appointment of Dr. James A. Crabtree as Chief Medical Officer of the Office of Foreign Relief and Rehabilitation Operations. Dr. Crabtree is loaned from the U. S. Public Health Service where he has served for the past 2 years as Secretary of the Health and Medical Committee of the Office of Defense Health and Welfare Services. He has also been the medical consultant in the Office of Lend-Lease Administration. He was formerly connected with the Tennessee State Health Department and was Deputy Medical Director of the Tennessee Valley Authority.

It was also announced that 3 Public Health Service medical officers had been assigned to North Africa and will depart for the field as soon as transportation facilities are available, representing the OFRRO. They are Drs. Dudley A. Reekie, Dorland J. Davis, and Michael L. Furcolow. Dr. Reekie is assigned as chief medical adviser to Robert L. Murphy, the Chief Civilian Affairs Officer on the staff of General Dwight E. Eisenhower. Mr. Lehman said that the dispatch of the 3 Public Health Service officers into the North African Field will strengthen the personnel of the OFRRO which has been in Algeria and French Morocco since January, 1943. Under the direction of Fred K. Hoehler, formerly the Director of the American Public Welfare Association, the OFRRO is making preparations for extension of relief to distressed civilian populations in Tunisia.

In commenting on the preparatory

work already accomplished by the Advisory Committee, Mr. Lehman said:

The War Department has not only assigned Colonel Simmons as its representative on the Advisory Committee but has also designated Colonel Ira V. Hiscock as Liaison Officer.

For many months, the Lend-Lease Administration has been making an estimate of drugs and medical supplies which may be needed after the liberation of occupied countries. The full coöperation of the National Research Council has been available in this work.

The Children's Bureau is contributing technical aid on child care and maternity problems. Through Dr. Boudreau of the Food and Nutrition Board of the National Research Council, the best scientific advice has been available concerning nutrition problems.

The American Red Cross is coöperating. Initial activities of the Office of Foreign Relief and Rehabilitation Operations in North Africa consisted of distribution of considerable supplies of powdered milk through child feeding stations, undertaken through the Red Cross. The Red Cross additionally has undertaken to supply certain laboratory and health supplies.

It was apparent that much necessary information concerning public health problems in countries likely to be reoccupied already was available in various departments in Washington and in data compiled by the Rockefeller Foundation. This information has been assembled, digested and interpreted, country by country, during recent months.

For many years the U. S. Public Health Service has assembled current reports on communicable diseases through the Offices of all American Consuls. The Advisory Committee on Health and Medical Care now has received this information, together with additional data available from the Army and Navy.

In order to deal with special problems, a number of subcommittees have been appointed. These include the following:

Nutrition, under Chairmanship of Dr. Boudreau and including Dr. Russell Wilder, Dr. W. H. Sebrell, Colonel Paul E. Howe, and Harold A. Vogel.

Sanitation of Environment, under Chairmanship of Dr. C.-E. A. Winslow, and including Dr. Abel Wolman, Colonel William A. Hardenbergh, and Senior Sanitary Engineer John J. Hoskins.

Maternal and Child Health under Chairmanship of Dr. Martha Eliot, and including Dr. Henry F. Helmholz, Dr. Edwards A. Park, Dr. Nicholson J. Eastman, Dr. Clifford Grulee, and Dr. Joseph Stokes.

Tropical Diseases, under Chairmanship of

Colonel Simmons with other members to be selected later.

Mr. Lehman said that Surgeon General Parran and members of his Committee have been in communication with a comparable group in Great Britain, which is organized under the Inter-Allied Post-War Requirements Committee.

Uniform standard lists of essential drugs are being agreed upon and information is being exchanged between my Committee and the London group. Dr. Melville MacKenzie, Chairman of the London group, has been invited to come to the United States for discussions. Dr. Raymond Gautier of Switzerland, who is associated with the League of Nations, also has been invited to come here for a conference concerning health matters.

In the field of health, as in other sectors of the task of bringing relief and rehabilitation to the liberated peoples, it is apparent that there will be needed not only the full participation of governments but also of all voluntary agencies and foundations experienced in this field. The task will be so tremendous that even the combined efforts of government and private agencies will be unable to meet all the demands.

The task of healing the wounds of war should engage the full efforts of all the United Nations and all freedom loving people everywhere. When our victorious United Nations' armies complete the liberation of the suffering peoples, it will no longer be a question of how much we contribute out of our largess to aid the starving and the sick, but rather how completely we are willing to share our limited joint resources to aid the sick and the starving.

PLAN OF SOCIAL SECURITY FOR CANADA

First the Beveridge Report for providing social security for England; then the Report of the National Resources Planning Board with recommendations toward a similar objective in the United States; and now postwar social life in Canada is under consideration. A definite legislative proposal for compulsory nation-wide health insurance and a plan to assure a minimum standard income to everyone have been submitted by Pensions Minister Ian MacKenzie to the House of Commons Committee on Social Security. The health insurance

measure would provide medical and dental services, hospitalization and drugs, to be paid out of wages, income contributions, and public funds. The cost is estimated to be one billion dollars a year. The social security plan was prepared by Dr. Leonard C. Marsh. In laying it before the House of Commons Committee, Mr. MacKenzie suggested that gaps in existing social legislation, the biggest of which is in the field of health, should be filled in at once. The report proposes establishment of a basic minimum standard of income according to which all social aids would be fixed; adjustment to this standard of existing non-contributory old age pensions and lowering the pension age; national compulsory contributory health insurance with free treatment for all; payment of allowances to parents for children under 16; upward revision of benefits to persons with dependents; pensions for disabled persons and widows; and payment of funeral benefits.

It is interesting to note that the Canadian Medical Association, on January 18, approved the adoption of the principle of health insurance and "a plan of health insurance which will secure the development and provision of the highest standard of health services, preventive and curative, if such plan be fair both to the insured and to all those rendering the service."

NEW PUBLIC HEALTH LEGISLATION IN NORTH DAKOTA

F. J. Hill, M.D., Acting State Health Officer, Bismarck, N. D., recently summarized the new legislation from the 1943 session of the Legislature. Authorization has now been obtained in an important new act for two or more adjacent counties or city-county units to pool their funds in order to create full-time local health units. Another law raises the minimum salary of the state health officer from \$4,200 to

\$5,000 and increases his term of appointment from 2 years to 4 years.

Another bill provides for the registration of engineers in order to protect the public against incompetent engineering services in the construction of public and private utilities, structures or equipment involving the safeguarding of life and the protection of property.

A law has been passed which reduces the number of local registrars from over 2,000 to a total of 65 in order to facilitate the issuing of birth and death certificates. Any citizen in North Dakota now may have a judicial determination of his birth record. According to Dr. Hill, this is a valuable procedure to determine birth confirmation for residents of foreign origin.

CHANGES IN MEDICAL OFFICERS, O.C.D., WASHINGTON

A. William Reggio, M.D., Boston, recently State Chief of Emergency Medical Service for Massachusetts, has been appointed Regional Medical Officer for the First Civilian Defense Region, succeeding Dudley A. Reekie, M.D. Dr. Reggio, a graduate of Harvard Medical School, was formerly an instructor in surgery at Harvard Medical School; assistant visiting surgeon, Massachusetts General Hospital, and consulting surgeon at the Massachusetts Eye and Ear Infirmary. The First Region includes the New England States.

Dr. Reekie, who was assigned to the Central Office of the Medical Division in Washington in January as Acting Chief of the Field Casualty Section, has since been assigned by the Surgeon General of the U. S. Public Health Service to the U. S. State Department to head a group of Public Health Service officers who will act as special advisers on health matters to Robert Murphy, Chief Civil Affairs Officer for North Africa.

To succeed Dr. Reekie as Acting Chief of the Field Casualty Section,

H. van Zile Hyde, M.D., Regional Medical Officer for the Second Civilian Defense Region (New York, New Jersey and Delaware), has been transferred to Washington. Dr. Hyde, formerly of Syracuse, N. Y., was the first Civilian Defense Regional Medical Officer appointed, having taken office in August, 1941. John J. Bourke, M.D., Deputy State Chief of Emergency Medical Service for New York, is now acting Regional Medical Officer for the Second Region.

David D. Rutstein, M.D., medical gas officer on the Washington staff, has resigned to become Deputy Health Commissioner of New York City. Before he joined the Medical Division, Dr. Rutstein was chief of the Cardiac Bureau of the New York State Health Department, Albany, N. Y.

AMERICAN FILM CENTER ISSUES LIST OF HEALTH FILMS

"Health Films," a descriptive list of 219 selected motion pictures arranged under 38 subject classifications has been issued by the Section on Health and Medical Films of the American Film Center, Inc., 45 Rockefeller Plaza, New York, N. Y. The Center is a non-profit educational organization supported by a grant from the Rockefeller Foundation.

The films listed, with few exceptions, are for lay audiences and include films which seem to be of value in the teaching of health whether they are produced under commercial or other auspices.

The pamphlet is obtainable from the American Film Center at 25¢ per copy.

RELOCATION OF PHYSICIANS

The War Manpower Commission on March 30 announced that approximately 600 physicians have changed their places of residence and practice in the last few months. The Procurement and Assignment Service, a Division of the Bureau of Placement, War Man-

power Commission, makes an effort to accomplish such relocations when the medical needs of the civilian population would be better served.

Figures compiled by the Procurement and Assignment Service come from 40 of the 48 states. Of a total of 587 relocations in these 40 states, 340 were directly due to action by the Procurement and Assignment Service. Five of the relocated physicians are women. A total of 214 of the 582 relocated male physicians are either over 45 years of age, or, if younger, disqualified for military service.

Although it is known that there have also been relocations in Kentucky, Delaware, Louisiana, Minnesota, Virginia, West Virginia, Oklahoma, and Vermont, the figures have not been reported. In many instances, the Procurement and Assignment Service reported, the assumption of increased duties by a decreased number of physicians remaining in an area has been seen as the best solution to a community's health problem. In a number of states ingenious medical care plans have been worked out locally which enable fewer physicians to care for more civilians. Among such states are Maryland, California, Oregon, Michigan, and Arkansas.

The Procurement and Assignment Service has an organization in each of the nine Army corps areas, consisting, in each case, of a chairman, two physicians, two dentists, one veterinarian, one hospital representative, one medical education representative, and one public health representative. Also in each state there is a state chairman for medicine, for dentistry, and for veterinary medicine.

RETIREMENT OF SIR MALCOLM WATSON

In its report for 1942 on the work of the Alameda County Mosquito Abatement District, California, Harold F. Gray says:

In presenting this Annual Report we wish to pay tribute to Sir Malcolm Watson, LL.D., M.D., C.M., D.P.H., F.R.F.P.S., L.M.S., who at the end of 1942 retired as Director of the Ross Institute of Tropical Hygiene at the London School of Hygiene and Tropical Medicine.

His brilliant demonstration at Klang and Port Swettenham in Malaya in 1901, that malaria could be controlled under mosquito control measures, initiated a long and distinguished career in tropical hygiene, culminating in his eventual recognition as the world's

greatest malariologist. His work has been characterized by originality, keen observation, a willingness to experiment, an open mind receptive to new ideas, fertility in adaptation of means to an end, and practical ability to achieve substantial results in disease control within reasonable cost limits.

His work has been an inspiration to those who have labored in this field, and he has graciously and generously shared with us his vast knowledge and experience.

In a world torn with war and destruction, it is indeed a pleasure to acknowledge the services of one who has done so much for the health and welfare of the people. By men like him this world is blessed.

WEST VIRGINIA LEGISLATION

The *Monthly News Letter* of the West Virginia State Department of Health records the passage of an act tightening the provisions relating to the suppression of prostitution and the passage of an act creating a division of cancer control in the State Department of Health. Another act of the Legislature gives the State Department of Health authority to detain and treat any person believed to be suffering from any venereal disease.

The confirmation of the appointment by Governor Neely of Dr. C. F. McClintic as State Health Commissioner has been announced. Dr. McClintic has served since March, 1941, in the unexpired term of his predecessor, Dr. A. E. McClue.

ECUADOR IMPROVES MEDICAL AND NURSING FACILITIES

Nelson Rockefeller, the Coördinator of Inter-American Affairs, Washington, D. C., has announced that widespread attention to public health and sanitation in the American republics includes new hospitals, new dispensaries and health centers, and sewage disposal plants which are already under construction in widely separated areas. These undertakings in the other Americas are directed largely by the local authorities, with technical aid and, in some cases, with financial assistance

provided by United States Government agencies.

It is announced that recently 30 carefully selected students began a course of instruction in nursing at the Escuela Universitaria de Enfermeras Profesionales of Quito, Ecuador, as the first project of its kind to be inaugurated under the Inter-American health and sanitation program. This project is coöperative among various Ecuadoran and United States agencies. Students in the nurses training course will spend the first 4 months receiving classroom instruction before entering clinical training. The curriculum will enable them to meet the requirements of the International Council of Nurses and to receive international recognition in their profession. Coöperating are the Ministerio de Provision Social, the Asistencia Publica, Universidad Central, Direccion de Sanidad, Cruz Roja and Concejo Municipal, as well as the Pan American Sanitary Bureau, the Rockefeller Foundation, and the Comision Sanitaria Norteamericana. The United States teaching staff includes Anne Cacioppo, the director, Kathleen Logan and Dorothy Foley.

WESTERN HEMISPHERE PROJECTS IN HEALTH

Dr. Albert R. Dreisbach, Assistant Director of the Division of Health and Sanitation, Office of Inter-American Affairs, Washington, recently announced that missions from the United States to Central and South American countries are contributing money, equipment, and personnel in medicine and sanitation to promote the health of this hemisphere. He stated that the budget amounted to \$25,000,000 and that the health and sanitation work was under the direction of Brigadier General George C. Dunham, U. S. Army, who is assigned to the office of the Coördinator of Inter-American Affairs.

Dr. Dreisbach stated that at present

units of Dr. Dunham's mission are operating in 13 of the 20 other republics in the western hemisphere, including Costa Rica, Honduras, El Salvador, Guatemala, Nicaragua, Haiti, Bolivia, Ecuador, Paraguay, Peru, Brazil, Colombia, and Panama. The individual units, with one exception, are headed by physicians, with sanitary engineers as chiefs of staff. Most of the field work is carried on by local doctors and local personnel.

NEW YORK EMERGENCY FOOD COMMISSION

Governor Thomas E. Dewey has announced the appointment of an emergency food commission "to foresee and meet situations as they arise." Among the objects of the commission are to help New York farmers to obtain maximum production and to guide adaptation of New York citizens "with foresight and common sense" to necessary changes of diet. Among the members of the commission is Dr. L. A. Maynard, Director of the Cornell University School of Nutrition.

U. S. PUBLIC HEALTH SERVICE APPOINTS SANITARIANS

The U. S. Public Health Service announces that the title "Sanitarian" has been adopted for commissioned reserve officers whose education and experience are in fields allied to public health work, but not in the specific field of medicine, dentistry, sanitary engineering, or engineering. Comparable qualifications with regard to education and experience for each rank are demanded for all titles. This title will replace the titles of Chemist and Industrial Hygiene Engineer which have been given recently to some officers assigned to industrial hygiene work.

COMMITTEE ON SOCIAL PROTECTION

A recent meeting was held in Washington of the Executive Committee of

the National Advisory Police Committee on Social Protection which brought together key representatives of private enterprises coöperating with law enforcement officials in the campaign for repression of clandestine prostitution and sex delinquency. At the conference the Army announced that the venereal disease rate among its men in January, 1943, was 25.2 per thousand per year as compared to 45 during January, 1942.

Among the units represented at the conference were the American Hotel Association, representatives of taxicab organizations, and the Distilled Spirits Institute, representing the liquor industry. The chairman of the group was Charles P. Taft, Assistant Director of the Office of Defense Health and Welfare Services.

TRANSCRIPTS OF SANITARIANS' VISITS AVAILABLE

Instructors in schools offering courses in sanitation and those responsible for in-service training have long expressed a need for more practical teaching material. One way by which schools of social work have met a similar need is to use verbatim records of actual home visits, whereas teachers' colleges have used verbatim reports of classroom work. More recently, the nursing schools have had access to authentic home nursing visits. Verbatim transcripts of sanitarians' inspections of homes and business establishments are now ready for release to instructors of sanitarians by the U. S. Public Health Service.

A brief description of the procedure used to obtain them is presented here in order that the transcripts may be of greatest service to those wishing to use them. More than 500 transcripts were collected concerning the work of 40 sanitarians in two cities in which the health departments carry out diversified inspection programs. In the smaller

city every inspector participated, but in the larger, the division director selected at random for participation inspectors engaged in each phase of the department's inspection work.

Expert stenographers accompanied the inspectors and recorded all conversations between them and those with whom they made contact in the course of their calls. Inspectors were requested not to make any special selection of premises to be visited but to carry on their daily activities in the usual manner.

Although the original stenographic reports include samples of every type of inspection activity carried on by the departments, duplication facilities limit the collection available for distribution to 23 transcripts. They are not offered as representative of sanitary inspections all over the country; however, they do indicate problems that are common to most sanitarians. In addition to: (1) Complaint Investigations (of several categories), the following types of inspections were selected for publication, (2) Residence (house), (3) Eating Establishment, (4) Bakery, (5) Delicatessen, (6) Grocery Store, (7) Chicken Market, (8) Milk Plant.

Since the supply of copies is limited, distribution is necessarily restricted to instructors in departments offering courses in sanitation and educational directors of health departments and other health organizations. Requests for this material should be addressed to the U. S. Public Health Service, Division of Sanitary Reports and Statistics, Washington, D. C.

DR. GETTING APPOINTED MASSACHUSETTS STATE COMMISSIONER OF HEALTH

Governor Leverett Saltonstall has recently announced the appointment of Vlado A. Getting, M.D., Dr.P.H., as State Commissioner of Health for Massachusetts, succeeding Paul J. Jak-

mauh, M.D., who has served for several years.

Dr. Getting since 1942 has been Health Commissioner of the City of Worcester, Mass. He received his medical degree from Harvard and the M.P.H. and Dr.P.H. from the Harvard School of Public Health, the latter in 1940. Dr. Getting has served as research assistant in epidemiology and preventive medicine at the Harvard School of Public Health and the Harvard Medical School. He has served as District Health Officer, as Epidemiologist, and as Technical Director of the Mosquito Survey in the Massachusetts Department of Public Health. He is a Fellow of the Epidemiology Section, American Public Health Association.

PROPOSED HEALTH LEAGUE FOR THE CARIBBEAN AND GULF AREAS

In 1938 Domingo Ramos, M.D., formerly Minister of Health of Cuba and now the Director of the Finlay Institute, Havana, proposed the establishment of a traveling institute for the promotion of sanitary and epidemiological knowledge in the area of the Gulf of Mexico and the Caribbean Sea. Dr. Ramos presented his idea at the Florida Public Health Association in 1938 and at a later session of the Florida Association held in Tampa. On the latter occasion, Felix Hurtado, M.D., at present Undersecretary of Health of Cuba, presented an official offer from President Batista of Cuba designating the Finlay Institute of Havana as one of the terminal stations of the institute. It was later proposed that Miami University in Florida should be another terminal station. The project was subsequently discussed at the International Conference of Caribbean Countries held in Port au Prince, Haiti, and again at the time of the American Public Health Association

meeting in Atlantic City, N. J., in 1941.

Dr. Hurtado visited New York City in April in order further to discuss such a sanitary league. At this time he pointed out that the states of Texas, Louisiana, Mississippi, Alabama, and Florida border on this region and that the relationships of these states and their ports with Cuba, with Mexico, with Guatamela, Honduras, Salvador, Nicaragua, Costa Rica, and Panama, as well as with Colombia, Venezuela, Trinidad, and the larger and smaller Antilles are very intimate and frequent. In this area, among other important institutions, are located the Finlay Institute of Havana, the Gorgas Institute of Panama, the School of Hygiene and Public Health of Mexico City, the School of Tropical Medicine, San Juan, Puerto Rico, and Tulane and Louisiana State Universities of Louisiana.

According to Dr. Hurtado, the proposed Institute would serve to link up this chain of institutions and promote their coöperative study of the special problems of this area. Dr. Hurtado proposes that the Pan American Sanitary Bureau should be urged to organize such a central link in coöperation with the American Public Health Association.

Dr. Hurtado proposes that a Round Table be assembled made up of the officials of the Pan American Sanitary Bureau, representatives of the U. S. Public Health Service, the U. S. Army, the U. S. Navy, the American Public Health Association, and delegates from the states and nations mentioned above. Dr. Hurtado would "cultivate the policy of continentalism as the best form for guaranteeing the happiness and well-being of our own countries." He would not create another special organization but rather would stimulate the practical organization of such an institute "to obtain stronger connections and more profitable interchange among the countries, states, and regions which are located within the

natural circle and linked for a variety of reasons." Dr. Hurtado made special reference to the desirability of steps like these which would prevent the international exchange of infections like yellow fever, virulent malaria, typhus fever, poliomyelitis, encephalitis, and other tropical and subtropical conditions.

PERSONALS

Central States

FRED T. ANDREWS, M.D., has resigned as Director of the Health Department of Bay County, Michigan, to become associated with the Fisher Body Division of the General Motors Corporation in Lansing.

N. BERNETA BLOCK, M.D., of Lansing, Mich., with the State Department of Health since 1937, has been named Director of the Alger-Schoolcraft Health Department with headquarters in Manistique. Dr. Block succeeds JEAN B. RUHL-KOUPAL, M.D., who has been named Director of Health District No. One including Crawford, Kalkaska, Missaukee, and Roscommon Counties.

RAYMOND V. BROKAW, M.D.,* Chief of the Division of Cancer Control in the Illinois Department of Public Health, Springfield, has been made Acting Director of the Champaign-Urbana Local Public Health District, succeeding R. F. REIDER, M.D., DR.P.H.† Under this plan the state will share with a local health district the services of a division chief in order most fully to utilize the available trained public health personnel in civilian life. Dr. Brokaw formerly was Executive Secretary of the American Society for the Control of Cancer.

* Fellow A.P.H.A.

† Member A.P.H.A.

HUGH A. COWING, M.D., was elected President of the Muncie, Ind., Board of Health on January 15.

ALBERT C. EDWARDS, M.D.,† of White Cloud, Mich., Director of the Fifth District Health Department, has resigned to become head of the St. Clair County Health Department.

MORELAND EMERSON, D.D.S., M.P.H., has been appointed Chief of the Dental Health Education Division in the Illinois Department of Public Health, Springfield. He is a graduate of the Washington University School of Dentistry and of the University of Michigan School of Public Health. He succeeds C. F. DEATHERAGE, D.D.S.,† who has resigned to enter private practice.

JAMES CARL FREED, M.D., of Attica, Ind., has been named Health Officer for Attica.

W. R. GIEDT, M.D., M.P.H.,† has been appointed Acting State Superintendent of Health of South Dakota, with headquarters in Pierre, succeeding JOHN FRANKLIN D. COOK, M.D., deceased.

DONALD M. HARRIS, M.D.,* of LeMars, Iowa, Medical Director of District Health Service No. 3, with headquarters in Spencer, was named to succeed CHESTER L. PUTNAM, M.D., M.P.H.,† in the Eighth District.

EARLE C. MCBRIDE, M.D., of Terre Haute, Ind., was elected President of the City Board of Health.

JAMES E. MCMEEL, M.D., of South Bend, Ind., was elected President of the South Bend Board of Health recently, succeeding GEORGE F. GREEN, M.D., who has gone into military service.

ALICE H. MILLER, C.P.H.,† recently resigned as Director of Health Education for the Tuberculosis Institute of Chicago and Cook County, to become Health Education Consultant with the U. S. Public Health Service, at Kinston, Lenoir County, N. C.

WILBURN O. B. NELSON, M.D., has been named Health Officer of Fergus Falls, Minn., to succeed the late WILLIAM A. LEE, M.D.

CARL N. NEUPERT, M.D.,† of Madison, Wis., has been appointed State Health Officer of Wisconsin, to succeed CORNELIUS A. HARPER, M.D.,* of Madison, who resigned as State Health Officer and as member of the State Board of Health. GUNNAR GUNDERSEN, M.D., of LaCrosse, succeeds Dr. Harper as member of the Board.

JOHN J. REHORST, M.D., has been appointed Health Officer of Fond du Lac, Wis., on a part-time basis until a permanent full-time appointment can be made, filling the vacancy that occurred when ROBERT L. DANA, M.D., obtained a leave of absence to enter military service.

ERWIN C. SAGE, M.D., M.P.H.,* who has been health officer in Des Moines County, Iowa, has resigned and has been commissioned Lieutenant Commander, M.C., U.S.N.R., and is at present stationed at the U. S. Naval Training Station, Bainbridge, Md.

REGNAR M. SORENSEN, M.D., C.P.H.,* Surgeon, U. S. Public Health Service Reserve, formerly of Des Moines, Iowa, has been detailed by the Service as Director of the Division of Venereal Diseases of the Kansas State Board of Health. He succeeds ROBERT H. RIEDEL, M.D.,† of Topeka, Kans., who has been given a leave to serve as Captain in the Medical Corps of the U. S. Army.

GEORGE C. STUCKY, M.D.,† of Charlotte, Mich., Health Officer of Eaton County, was recently placed in charge of the Barry County Unit. The two units were combined for the duration.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. A. L. TATUM, Professor of Pharmacology at the Medical School of the University of Wisconsin, Madison, Wis., has been awarded the Charles Mickle Fellowship at the University of Toronto, for his work in the introduction of mapharsen for the treatment of syphilis and for other studies in pharmacology. The Fellowship is in the nature of an award, being the annual income from an endowment of \$25,000.

Eastern States

FRANK A. CALDERONE, M.D., M.P.H.,* Secretary of the New York City Department of Health, has been appointed Deputy Health Commissioner, to succeed GEORGE T. PALMER, DR.P.H., resigned.

DR. VINCENT DU VIGNEAUD, head of the Department of Biochemistry at Cornell University Medical College, New York, N. Y., recently addressed the Central Pennsylvania Section of the American Chemical Society on "Trans-Methylation as a Metabolic Process." According to *Science*, it was emphasized that trans-methylation is the first new principle introduced into the science of nutrition since the discovery of the vitamins.

CARL H. FLINK has been appointed Technical Secretary of the American Society of Heating and Ventilating Engineers, New York, N. Y.

MARY ESTELLE INGOLDSBY, R.N., of New York, N. Y., has been appointed Industrial Nurse Consultant with the Bureau of Industrial Hygiene, West Virginia State Department of Health, Charleston.

ELNA I. PERKINS,† of Boston, Mass., Treasurer of the Massachusetts Public Health Association, joined the Division of Industrial Hygiene of the U. S. Public Health Service as Associate Health Education Specialist, as of April 1.

DAVID D. RUTSTEIN, M.D.,* has been

appointed as Medical Deputy Commissioner of Health of the New York City Department of Health. He will be in charge of the city's gas defense preparations as well as the nutrition and industrial hygiene programs of the department. Dr. Rutstein is a graduate in medicine from Harvard, has served with the New York State Department of Health as Medical Consultant in the Bureau of Pneumonia Control and as Chief of the Cardiac Bureau, and recently has been consultant in the medical aspects of chemical warfare, U. S. Public Health Service.

EDGAR J. STAFF, SN.C.,† formerly with the Rhode Island Department of Health, is a Major in the Sanitary Corps of the U. S. Army, now attached to the 1st Service Command, with offices in the Army's central laboratory for New England which is located at the old Harvard Bussey Institute, Jamaica Plain, Mass.

WILLIAM J. TIFFANY, M.D., of Albany, N. Y., has resigned as Commissioner of Mental Hygiene of the State of New York, effective April 1.

Southern States

CHARLES E. BALLARD, M.D., of Alledale, S. C., has been appointed Director of the Pickens-Oconee Health Unit.

ANTHONY J. BOROWSKI, DR.P.H.,† has resigned his position with the Federal Works Agency and has accepted a position as statistician with the Division of Records & Statistics, Department of Public Health, Richmond, Va.

HARRY M. BROWN, M.D., physician at the duPont plant at Belle, W. Va., has been added to the staff of the West Virginia State Health Department as part-time consultant in the

* Fellow A.P.H.A.

† Member A.P.H.A.

Bureau of Industrial Hygiene, filling the vacancy created by the resignation of J. W. CROSSON, M.D.

SAMUEL P. BURT, M.D., of Louisburg, N. C., has been named Health Officer of Franklin County to succeed RICHARD F. YARBOROUGH, M.D., of Louisburg.

HAZEL C. CAMERON, formerly of the teaching staff of the West Virginia University at Morgantown, has been appointed Nutritionist in the Division of Maternal and Child Health, West Virginia State Department of Health, Charleston, filling the vacancy caused by the resignation of MRS. MABEL PERRY POLAN, who is now State Nutritionist with the Texas State Department of Health, Austin.

CHARLES M. COVINGTON, M.D., of Alto, Tex., was recently appointed Epidemiologist of the Travis-Bastrop County Health Unit, to succeed HUGH SHANE, M.D., of Austin, who entered military service.

HUGH S. CUMMING, M.D.,* formerly Surgeon General of the U. S. Public Health Service, Washington, D. C., and for many years director of the Pan American Sanitary Bureau, has received an honorary degree conferred by the University of Santo Domingo recently.

LELAND H. EVANS, D.D.S.,† Passed Assistant Dental Surgeon (R), U. S. Public Health Service, Bethesda, Md., has been assigned to the Division of Industrial Hygiene, Michigan State Department of Health, Lansing, as consultant on industrial dentistry.

WILLIAM O. FUNDERBURK, M.D., of Elkhart, Tex., was recently named Health Officer of Anderson County, succeeding FRED E. FELDER, M.D., of Palestine. Dr. Funderburk formerly served as County Judge.

GEORGE G. HOWARD, Passed Assistant Surgeon, U. S. Public Health Service Reserve, has been placed in

charge of the Parker and Palo Pinto County [Texas] Health Unit.

EVERETT A. KING, M.D. of Hardinsburg, Ky., Director of the Tricounty Health Unit of Breckenridge, Hancock, and Meade Counties, Ky., has been named full-time Health Director for Evansville and Vanderburgh County, Indiana.

RALPH CHRISTOPHER LEGGO, Surgeon, U. S. Public Health Service Reserve, has been placed in charge of the Industrial Hygiene Service of the State Department of Health of Ohio. Dr. Leggo was recently Industrial Hygiene Physician for the Missouri State Board of Health at Jefferson City, Mo.

F. A. MUSACCHIO, M.D., M.S.P.H.,† formerly of Franklin, La., has been appointed Director of the St. Joseph County Health Department, Centreville, Mich.

WILLIAM B. NELSON, M.D.,† of Bay Minette, Ala., Health Officer of Baldwin County, has been placed in charge of the health units at both Baldwin and Escambia Counties.

ALBERT M. PRICE, M.D.,† of the staff of the West Virginia State Department of Health, Charleston, has been given leave of absence until July 1 to serve as Acting Director of the Kanawha County Health Department with headquarters in Charleston.

COLONEL JAMES STEVENS SIMMONS, M.C., Director of the Division of Preventive Medicine, Office of the Surgeon General, U. S. Army, was appointed a Brigadier General in the Army of the United States by the President on April 2, 1943, with rank from March 14, 1943.

LEWIS HILL WEED, M.D., Professor of Anatomy at the Johns Hopkins University School of Medicine, Baltimore, Md., has been appointed

* Fellow A.P.H.A.

† Member A.P.H.A.

Chairman of the Medical and Health Advisory Committee of the American Red Cross, Washington.

OLIVE WHITLOCK, R.N.,* Associate Public Health Nursing Consultant to the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., has resigned following her recent marriage but will serve as Special Consultant to the U. S. Public Health Service on Industrial Hygiene Nursing. Miss Whitlock was formerly chief nurse in the Oregon State Department of Health. During the two years she has been associated with the Division of Industrial Hygiene the number of Industrial Hygiene Nursing Consultants has increased from 3 to 18. *Industrial Hygiene* reports that "special credit is also due Miss Whitlock for her leadership as chairman of the American Public Health Association committee which conducted the nation-wide survey to study the duties of nurses in industry." This survey will shortly be published in the *American Journal of Public Health*.

CHARLES L. WILLIAMS, JR., M.D.,† of New Bern, N. C., Assistant Surgeon, U. S. Public Health Service, has been appointed Health Officer of Lenoir County, to succeed ZEBULON V. MOSELEY, M.D.,† of Kinston.

Western States

WILLIAM J. O'CONNELL, JR.,† of San Francisco, Calif., has organized with L. L. CARTER, a firm called Technical Consultants which has for its particular interest consultation on the biological, chemical, and technical problems arising from the use of water.

ARTHUR L. RINGLE, M.D., of Portland, Ore., has been appointed District Health Officer with headquarters at Walla Walla, to succeed JOHN A. KAHL, M.D., M.P.H.†

WILLIS E. SMICK, M.D., of Seattle, Wash., has been named Health Officer of Cle Elum.

GEORGE B. WRIGHT, M.D., of Kalispell, Mont., has been named Health Officer of Flathead County, to succeed ALBERT A. DODGE, M.D., of Kalispell.

Paraguay

DR. FRANCISCO A. MONTALDO has been appointed Director of the recently created Department of Nutrition in the Ministry of Public Health of the Republic of Paraguay. Dr. Montaldo specialized in the study of nutrition for two years at the Institute of Nutrition at Buenos Aires on a scholarship provided by the government.

DEATHS

JOHN FRANKLIN D. COOK, M.D., State Superintendent of Health, Pierre, S. D., died January 17.

A. GRANT FLEMING, M.C., M.D., D.P.H., F.R.C.P.,* of Toronto, formerly Dean of the Medical School at McGill University, Montreal, and Professor of Public Health and Preventive Medicine at McGill, died April 9. Dr. Fleming was elected a member of the American Public Health Association in 1920 and a Fellow in 1930. He was A.P.H.A. Vice-President in 1939 and an elective member of the Governing Council 1937-40 and 1940-43. He was a member of the Committee on Administrative Practice 1936-44. At the time of his death Dr. Fleming was President-elect of the Canadian Public Health Association and had been slated to head the new Preventive Medicine Unit caring for the general health of Canada's army.

Medical Care for Dependents of Men in Military Service*

STUART W. ADLER, M.D.

*Director, Division of Maternal and Child Health, New Mexico Department
of Public Health, Santa Fe, N. M.*

GUARDING the health of the families of men in the armed forces becomes a very real problem as our nation swings into the full war effort. When men by the millions are moved about the face of the globe, many problems are left behind. One of these is securing adequate medical care for dependents at home. Maternity care becomes a vital concern of the men in service as well as of their wives from whom they are so often separated. The economic adjustments made necessary in wartime in hundreds of thousands of homes raise the question as to whether good care will be available to the expectant mother.

Realizing these facts, far-sighted advisory groups have for several years assisted in making plans for just such an eventuality as now confronts us. To provide care for women during child-bearing and to assist in taking care of their sick infants, the Children's Bureau in the spring of 1942 set aside certain

funds. These were specifically designated to be used to insure adequate medical and, when necessary, hospital care in soldiers' families when such attention was not otherwise available. The responsibility for administering this program was delegated to the various state health agencies already conducting maternal and child health programs. Less than \$200,000 was available when the Children's Bureau brought the matter to the attention of the several states. By October, 1942, requests for funds had been submitted from 26 states. These were approved and represented funds totalling \$308,000 to meet the immediate needs.

At first there could be no definite idea as to the probable extent of the need. Experience to date suggests that there will be a steady increase in the demand for these services. This will probably continue for the duration of the war and for a short period thereafter. Surveys had indicated that in an American army of five million men, 20 per cent would be married and that 5 per cent of all babies born in the year beginning July 1, 1942, would

* Based on paper presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

have fathers in the armed services. It is thought that in another year the figure would be nearer to 10 per cent. At present more than 400 babies are being born each day of soldier-fathers. As had been predicted, the wives of soldiers began to seek assistance for maternity care through various agencies by the spring and summer of 1942. The Red Cross surveys indicate that probably more than 25,000 wives of servicemen are seeking obstetric and pediatric care each month.

By December 1, 1942, requests from the health agencies of 39 states for funds to care for servicemen's dependents totalled over \$2,250,000. This was the estimated amount necessary to complete the program during the current fiscal year.

A deficiency act has now been approved by Congress and signed by the President carrying \$1,200,000 to meet the emergency. This action of the Congress is for an emergency period which is defined as the duration of the present war and 6 months thereafter. An appropriation of at least \$6,000,000 will be sought annually to provide for the continuation of these special types of care in the families of certain groups of men in military service.

New Mexico had a plan approved early in July, 1942, and the first applications were received August 1 of that year. Any new program in public health is always interesting. Like the ever popular jig-saw puzzle, the many parts of this new plan were well scattered and had to be brought together. There was no assurance as to just what the final picture would be. There are at least three fixed factors to serve as guides: the amount of money available, the time limits placed upon its expenditure, and the estimated need for the service. The first two of these are very definite, the last is still a matter of guess work.

Other parts of the puzzle that have

to be considered are the personnel to be used, the hospitals available, the standards of care, the extent of the services, the machinery to make the plan operate effectively, suitable record forms, an accounting system, and, finally, the question of what to do with the hundreds of variants that arise once the program is under way.

From the start, the situation in New Mexico presented one problem after another which had to be adjusted. The approved plan represented a sincere attempt to provide the care in the manner intended. Before the program had been in operation three months, numerous alterations were necessary. Changes had to be made in order that the underlying principles desired by the sponsors could be carried out. Unexpected difficulties in the actual operation of the plan are still being encountered.

Since the application of the national program to New Mexico is being described in this paper, it is necessary that a brief picture of the state be presented. New Mexico is famous for its scenery and climate. Chambers of Commerce make much of this, and rightly so, but New Mexico is also a land of social problems which are very different from those of Ohio, Alabama, or Maine. Just a few of the factors which influence the approach to any health problem may well be mentioned. With a population of only 550,000 scattered over the fourth largest of these United States, it is easily seen that problems of communication are real and social handicaps numerous. In addition, there is the racial and language difficulty. In some counties the Spanish speaking portion of the population is above 90 per cent. The fact that a vast majority of families are living at a low income level, further complicates attempts to render health and welfare services.

Many of these factors account, in part at least, for the unenviable health

reputation which the state has earned. Infant mortality, here as elsewhere, is a good index in estimating health conditions. From 1930, when the rate for the state was 145, there has been a drop to 93.7 in 1941. Maternal mortality rates are well above the average for the whole country.

These facts are presented to show that there is a constant need in New Mexico to supervise and assist those who, for economic reasons, will not secure adequate medical care unless such assistance is literally placed in their way. This is true in many of the soldier homes in New Mexico.

New Mexico is not humming with defense or war activity as are many other states. A total of fifteen areas busily engaged in war activity are found in the state, these being principally air bases and mining areas. The soldier population is relatively small compared with other sections of the country, but it is large in proportion to the number of civilians, and this soldier population is steadily increasing. We already have, scattered throughout the vast area of our state, the families of more than 2,000 New Mexico soldiers who were at Bataan or on Corregidor.

The families of men in the service can be divided into two groups: the old-time residents who have stayed in remote and often isolated regions, and another group which is made up of new residents who have come to New Mexico to live near their men in the camps and have stayed in the larger population centers when their men have been sent away for foreign duty. Both of these groups need assistance from the plan under discussion. Each group presents a somewhat different problem.

WHAT THE PLAN OFFERS

The plan for the care of wives and children of men in the armed services, as it is operating in New Mexico, is,

very briefly, as follows: Maternity service including prenatal, delivery, and postpartum care is provided in either a hospital or the patient's home. The care given is by a doctor of medicine of the patient's choice. This service also includes the care of the new-born infant. At least five prenatal visits are required, and the service terminates only when mother and baby have been examined 6 weeks after the delivery. When complications or abnormalities arise in the course of maternity care, consultation is available and any reasonable amount of indicated special care can be authorized. Care of infants under 1 year of age, for any illness, is also provided, and can be secured from an approved doctor of medicine in his office, the patient's home, or at an acceptable hospital.

In both types of service the choice by the family of an attending physician is assured with very few restrictions. It is impossible in New Mexico to use specialists in other than a few locations. However, if in some parts of the state, physicians with somewhat inferior training have to be used, such service is definitely preferable to maternity care by a midwife or untrained person. A recent poll of the physicians in New Mexico showed a ratio of 1 doctor (M.D.) who can be used in the program under consideration to approximately 3,000 of the population.

Among the expectant mothers in the families long resident in New Mexico, care by midwives at the time of confinement is all too prevalent and years of teaching are only now being rewarded by an increase in the percentage of cases delivered by physicians.

Those women who have come into the state recently, and who are eligible for service under the plan to care for soldiers' wives, have probably come from sections of the country where they could obtain good obstetrical care. If they reside near army camps close to

the cities or small towns in New Mexico, they will find facilities for a very satisfactory type of professional service and hospital care.

MAKING APPLICATION

Any woman desiring service for herself or her sick infant may make application. A form is signed by the mother stating that her husband or the father of the sick infant is in the service of the United States. The service at first was offered to the families of men in all branches of the military forces below the rank of a commissioned officer, regardless of the financial status of the family. Funds now available by the recent action of Congress place a limitation upon the expenditure in that it applies only to the four lower grades in the various armed services. Applicants who qualify otherwise are refused only when it can be established that satisfactory service is available to them from other sources.

When a physician has been selected by the applicant, the forms are completed and signed by the applicant and the physician, both of whom agree to abide by the conditions of the State Department of Public Health plan. If all conditions are met, the service is authorized by the Director of Maternal and Child Health.

FEES PAID

Approved physicians and hospitals agree to accept the care of the case at the fee stipulated by the state agency and to make no further charge against the patient or her family. The fee for complete maternity care is \$35. Allowance is made for any unusual condition that may arise.

When hospital care is indicated, the hospital chosen by mutual consent of the patient and attending physician must be one that is acceptable to the State Department of Public Health. An agreement to provide satisfactory

care at stipulated rates is made with each hospital before approval is granted to participate in the plan.

The rate paid to hospitals for obstetrical care is \$40 for 10 days' complete care at ward level. Allowances are made for "extras" in connection with abnormal deliveries. The payment for these additional items is made by agreement as the situation arises. Care of sick infants is paid for at an agreed rate per day which differs somewhat in various hospitals, the average being \$2.50 a day.

There is no reason to be proud of the type of hospital which it is necessary for patients to use in some parts of our state. On the other hand, a number of very satisfactory small hospitals, equipped for ordinary emergencies, are serving residents in isolated areas of the state. Recently a patient had to be brought to the nearest hospital, a distance of a hundred miles, a week in advance of the expected date of confinement. One good rain could have made the only road impassable for several days. At the hospital in question, excellent care was provided by a competent obstetrician.

The question has been raised as to the possible preference for home delivery in some cases in view of the fact that delivery at home might prove as safe as in the hospital. In answer, it can be said that use of a hospital is made practically mandatory in view of the fact that many physicians refuse to deliver any patients outside of the hospital. The plan permits payment for home delivery where physician and patient request it.

When service has been authorized, notice is sent to the attending physician, the hospital, the mother, the local health unit, as well as any referring agency.

FOLLOW-UP SERVICES

All of these notifications are made

for obvious reasons, but it might be pointed out that the contact with the public health unit is to give the nurses an opportunity to become acquainted with the patients as early in pregnancy as possible. A great deal of assistance can be offered in some cases. Patient's with an anxiety complex can be assured of the friendly services these nurses offer.

The nurses help in adjusting problems of many kinds: interpreting physicians' orders, checking attendance at prenatal examinations, adjustment of possible household problems involving outside help or housekeeper service, guidance where financial problems have become acute, preparation of layettes, arrangements for hospitalization, and, probably most important of all, making the home visits which help to guard against preventable complications.

After the patient's return from the hospital, the nurse's visits are much more effective if the contact with the patient has been a prenatal one. Her invitation to have the mother take advantage of well child clinics will probably result in helping to keep the new-born baby well.

At the termination of a case, or when the postpartum examination of mother and infant has taken place, the maternity record form is completed by the physician and returned to the State Health Agency. Payment for service is made to the doctor and the hospital by check from the State Department of Public Health.

The care of a sick infant is initiated in the same manner as for maternity service. A patient suffering from any condition is accepted for care, and consultation provided if possible when needed. When the patient is discharged, a brief clinical summary must accompany the physician's bill for services.

Any individual or agency who learns of an expectant mother or her sick in-

fant can aid in initiating an application for assistance.

OTHER PROBLEMS

A few of the problems which still confront those responsible for the operation of this plan might well be mentioned.

Refusal to stay in the hospital for 10 days has been found to be due to indifference of the physician, the desire of hospital authorities to speed the turnover where institutions are crowded, or to anxiety over household problems such as the care of small children at home. The first two can be guarded against by kindly suggestion and perseverance. To help the last difficulty, arrangements can sometimes be made in advance to provide adequate help. This will solve the problem for some homes. Rural homes suffer less from this particular difficulty. Care in a good hospital is urged in the hope that it will stimulate interest in getting the best possible obstetric care.

Another problem arises from the reluctance of physicians to submit adequate records which are the principle means of judging standards of care.

A further difficulty is that some hospital superintendents feel that they are entitled to as large fees as they can possibly get. It is true that the costs in small institutions are such that the fees paid under this plan represent little opportunity for profit. Under the Children's Bureau plan for payment of properly estimated per diem costs to be initiated in the next fiscal year, this difficulty will no longer exist.

It might be noted that physicians have taken a very liberal attitude toward their fees and few complaints have been registered. Assured payment for service from a group which, as individuals, are frequently guilty of non-payment of doctors' bills, the physician has every reason readily to accept care of these cases.

COMPLETED AND PENDING SERVICES

By January 1, 1943, all funds allocated to New Mexico (\$19,000) had been earmarked to provide for 335 applicants whose care had been authorized.

All physicians in the state were then notified that there would have to be a lapse in the service until additional funds were secured. There was a prompt falling off in the rate of filing applications, due in part to the unwillingness of physicians and hospitals to accept cases without assurance of payment. Despite this fact, during January and February 225 new applications were received and most of these have now been approved.

Maternity care has been given by 45 different doctors at an average cost of \$76 per case for medical and hospital care. All cases were hospitalized except 2. The average hospital cost was \$42 per case.

The program has meant a great deal to both those receiving the care and also to their families. This is attested by opinions expressed to workers in Red Cross home service, health and welfare department workers, and many

others who have been in touch with the situation. Pathetic letters expressing the great need of many of the young mothers have accompanied the requests for the service and many have expressed the satisfaction experienced from having had the opportunity to secure good care when such a prospect often seemed remote.

Beside the actual benefits of medical and hospital care for the mother and her babies, the educational value of the program has been apparent. A realization of what constitutes good obstetric care has come to many homes and rural areas of the state which have never known anything but the care by midwives in crowded adobe homes without basic conveniences.

The people of New Mexico have enjoyed real benefit from this program. It is a venture into a new field of health activity that has been well received. Additional social security is made possible by this plan for the families of our fighting men at a time when this adequate care means much to morale on both the battle front and the home front.

Statistical Aspects of Coding and Tabulating Medical Data on Birth and Stillbirth Certificates*

J. V. DEPORTE, PH.D., F.A.P.H.A., SYLVIA L. PARKER, PH.D.,
AND ELIZABETH PARKHURST

*Director, Division of Vital Statistics, Assistant Statistician, and Senior
Statistician, New York State Department of Health, Albany, N. Y.*

THE war, which is now affecting directly or indirectly the entire human race, has made the protection of the life and health of the coming generation a more vital obligation than ever before. The popular adage coupling childbearing with child-burying epitomizes the experience and fatalistic attitude of centuries. Even in 1906 infant mortality, in the words of Sir George Newman,¹ was a problem because it was not decreasing, while the general death rate was moving downward. Almost coincident with the time of this observation the development and application of what have since become elementary measures, such as the pasteurization of milk, the protection of water supplies, and immunization against diphtheria, demonstrated the preventability of a great many of the deaths in infancy. For example, thirty years ago for every 1,000 children born alive in New York State, 101 died before reaching their first birthday; in 1941 the rate of mortality was but 33.

One need go back only a few years to find an attitude of almost com-

placent resignation toward the shamefully high maternal mortality; it was not until representative organizations of the medical profession instituted searching inquiries into the causes and circumstances of such deaths, and discovered and publicized the shortcomings in obstetrical practice that this mortality commenced to decline. In New York State the success of such efforts, combined later with the new chemotherapy, became evident in 1934, when the maternal mortality dropped to 51 deaths for every 10,000 live births and stillbirths, as compared with an average rate of 60 for 1931-1933, and 61 in 1933. In the following years the downward movement continued at an accelerated pace, and in 1941 the rate was only 22, a reduction of 64 per cent in 8 years.

Even with the present low rates, however, the loss of life of mothers and infants from diseases and conditions associated with childbirth is still unnecessarily high. To make further progress possible, expert opinion² stressed the need for certain basic medical information that was not available with respect to all births. This information could be continuously and currently secured only by means of birth and stillbirth certificates. Therefore, the content of the medical part of

the standard certificate of stillbirth was elaborated, and a set of optional questions added to the standard form of birth certificate. The stillbirth certificate and the optional questions on the birth certificate, as employed by the New York State Department of Health* beginning January, 1940, are shown in Figures 1 and 2.

COMPLETENESS AND ACCURACY OF

MEDICAL INFORMATION

Since the medical questions are an

integral part of the stillbirth certificate, they are practically always answered. The questions on the certificate of live birth do not constitute a legal part of the certificate, and the physicians are under no compulsion to answer them. It is, therefore, particularly gratifying that answers to the latter questions appear on somewhat more than 90 per cent of the birth certificates; the supplementary questions are wholly disregarded on 7 per cent; weight alone is given on approximately 2 per cent. The incomplete certificates are concentrated in comparatively few counties—in 1941 more than half of

* In New York City a special detailed report form has been in use since 1938.

the incomplete certificates were filed in only 6 of the 57 counties.

Since the purpose of the questions on the certificates is not only to ascertain the incidence of complications and of the methods of delivery but also to measure the neonatal, stillbirth, and maternal mortality associated with these factors, every certificate of an infant or maternal death is matched with the corresponding birth certificate. In our procedure this is accomplished in the following manner: For every infant death the date and place of birth are added to the punched death card (which is a combined statistical and index card). Once a month all of these cards are duplicated, foundlings and births out of state are excluded, the remaining cards are sorted by month of birth and soundexed name, and then used as index cards with which to search the monthly birth indexes. If the matching birth certificate is not found, an inquiry is sent to the

registrar of the community where the birth occurred. Certificates of puerperal deaths, except those stated to be associated with an undelivered pregnancy or an abortion of less than 5 months' gestation (the reporting of which is not required by the New York State Public Health Law), are used in similar manner in a search of both live birth and stillbirth indexes. If the matching birth certificate cannot be found, a form letter is sent to the physician who signed the death certificate asking for the period of gestation and the date and place of birth. At the end of the year a card is punched for every infant or maternal death combining, on the same card, the pertinent data from the matched birth and death certificates.

The comparison of the birth and stillbirth certificates with the death certificates indicates that in an indeterminate number of cases the replies to the additional questions are not suf-

FIGURE 2

SUPPLEMENTAL REPORT BY PHYSICIAN

NOT TO BE COPIED INTO LOCAL REGISTER

The answers to the following questions, which the New York State Department of Health is asking the physician in attendance at this birth to supply, will form the basis for more intensive work toward further progress in the protection of the lives of infants and mothers.

All of the facts entered by the physician on this side of the certificate will be considered confidential and will be used only for statistical purposes. None of them will, under any circumstances, appear in the certifications or transcripts issued by the Department.

Pregnancy, complications of: NONE	Were any operative or instrumental procedures used? YES
	Specify: MID. FORCEPS
	Indications: CONTRACTED PELVIS
Labor, complications of: NONE	Did baby have any
	(1) Congenital malformation? NO Describe
	(2) Birth injury? NO Describe
Weight of baby at birth: 7 lbs. 5 ozs.	

INSTRUCTIONS

In order to comply with the law this must be filled out within five days of the date of birth.

Registrars are instructed to write throughout "legible, erasure, interlineation, correction."

Note: If a mistake is made in the certificate, it may be corrected before the certificate is accepted for registration, another blank may be filled in correctly and substituted for the erroneous certificate; but no certificate of birth after the date of birth.

physician's signature: (1) Is incompletely filled in; (2) Is not dated, grossly soiled or defaced, inaccurate; (4) Contains any

(7) A blank (Form VS No. 33) will be supplied by the Local Registrar

Residence is outside the limits of the city or village. It is, therefore, important that the question "Is residence within the limits of city or incorporated village?" always be answered by "yes" or "no."

Statement of Occupation. Male some entry in this section for each parent. For a woman whose only occupation is that of home housework, write housework in answer to item 18 and own home in answer to item 19. For a person engaged in domestic service for wages, however, designate the occupation by the appropriate terms, as housekeeper—private family, cook—hotel, etc. For a person who has no occupation whatever write none.

In stating the occupation, avoid the use of such indefinite terms as "employee," "worker," "operative," "engineer," "mechanic," "clerk," etc. Find out the particular kind of work done and return that, as spinner, weaver, etc.

In stating the industry or business, avoid the use of such general terms as "store," "factory," "mill," etc. State the particular kind of store, factory, mill, etc., as grocery store, soap factory, cotton mill, etc.

Physicians are required to report of *Wolffia neovatorum* (bolies' sore eyes) to local health officer within 24 hours from the time when first seen.—SANITARY CODE, CHAP. II, R.G. 1 AND 2. A midwife, nurse, or other person having charge must report immediately to health officer or physician inflamed, reddened eyes of infant within the age of 2 weeks.—PENAL LAW, §152.

ficiently descriptive and at times incorrect. A birth certificate may contain no reference to a complication of pregnancy or labor, but the corresponding maternal death certificate, filed on the same date and signed by the same physician, may bear a positive statement, such as toxemia, placenta previa, or heart disease. For example, in one case the cause of death was given as chronic cardiovascular disease, difficult delivery with breech presentation; the woman died 16 hours after delivery, but the birth certificate mentioned only abruptio placenta as complication of pregnancy or labor. Errors are also discovered through the check of the certificates against the reports of positive Wassermann tests filed with the Division of Syphilis Control. Here it is occasionally found that a birth certificate contains no mention of syphilis as a complication while the woman was, in fact, under treatment for syphilis. Again, a birth injury or congenital malformation may be entered as the cause of an infant's death, while the corresponding birth certificate contains no mention of birth injury or malformation. In analyzing or interpreting the tabulated data it is, therefore, important to bear in mind that the different complications are in varying degree *understated*.

CODING OF COMPLICATIONS OF PREGNANCY AND LABOR

From a survey of the manner in which the certificates are filled out, it soon became apparent that it would be impossible to make any attempt to separate complications of pregnancy from complications of labor and indications for operation. For instance, the birth certificate reproduced here (Figure 2) states "none" under both complications of pregnancy and complications of labor, and yet "contracted pelvis" is given as the indication for the mid forceps operation. The sample

stillbirth certificate (Figure 1) gives "prematurity" under complications of pregnancy and complications of labor, but "face presentation with cord twice about neck" is entered as cause of stillbirth. Another stated *no* complications of pregnancy, persistent occiput posterior, prolonged second stage, and secondary dystocia as complications of labor, but gave preëclamptic toxemia as cause of stillbirth. There are many such cases. It was therefore decided to code and tabulate two complications whenever two sufficiently distinct complications were stated anywhere among the items. By sufficiently distinct, we mean that we do not code two forms, types, manifestations or symptoms of toxemia on the same case, or two of dystocia, but we do code both toxemia and dystocia, or toxemia and placenta previa, or dystocia and diabetes, etc. In the comparatively rare cases where more than two distinct complications were stated, only two were coded during 1940 and 1941, attempting to retain the more serious conditions.

The preparation of the code, which had the patient and invaluable advice of Drs. Elizabeth Gardiner and Helen Owen of the Division of Maternity, Infancy, and Child Hygiene, commenced with the listing of *all* terms appearing on the certificates. The extensive compilation (there were found 32 different ways of stating deviations in the bony pelvis and 30 of uterine inertia) was first compressed into 60 items and thus used in 1940 and 1941. Following the initial tabulations of the 1940 data, the code was further condensed to 36 terms and it is these terms that appear in Table 1. This table summarizes the incidence of the various complications of pregnancy and labor among the live births and stillbirths occurring in the 18 month period from July 1, 1940, through December, 1941, and the neonatal and maternal deaths associated with them.

TABLE 1

Incidence of Complications of Pregnancy and/or Labor
New York State, Exclusive of New York City, July, 1940–December, 1941

	<i>Live Births</i>	<i>Still-births</i>	<i>Deaths under 1 Month</i>	<i>Maternal Deaths</i>
Total	143,218	3,602	3,602	231
Questions on complications answered	130,152	3,364	3,244	219

{ Postpartum hemorrhage	561	1	17	5
{ Rupture of uterus	10	16	2	6
{ Surgical shock	16	3	4	3
{ Diseases of the heart	508	37	27	19
{ Syphilis	187	36	13	1
{ Chronic nephritis	99	40	10	..
{ Other diseases of the genitourinary system	130	9	8	1
{ Tuberculosis	88	2	3	1
{ Pneumonia, influenza, bronchitis, acute respiratory	180	30	24	3
{ Diabetes	93	32	14	3
{ Anemia and other blood diseases	210	18	13	2
{ Pelvic tumors	147	30	15	2
{ Appendicitis	80	4	11	..
{ Diseases of the endocrine glands	131	26	6	3
{ Mental and nervous diseases	76	5	3	1
{ All other intercurrent diseases	430	19	28	2
{ Accidents and over-exertion	98	83	25	2
Disregarded in 1942				
{ Infarction of placenta, etc.	19	24	3	..
{ Dry labor	570	28	29	..
{ Edema	107	8	4	1
{ Varicosities	268	..	10	..

The brackets and marginal notations indicate the major changes made in 1942 either by combination of terms or by further subdivision.

In condensing the original list of 60 complications to the present 36, a few terms were given up entirely: placental infarction, dry labor, edema, and varicosities; most of the condensation was made by combining related terms, such

as, all malpresentations other than breech, all lacerations, all previous pelvic trauma, all acute respiratory illness. The largest change of this kind was the combination of six separate terms into "other dystocia." * It was

* Persistent occiput posterior, Bandl's ring, anomalies of the soft parts, disproportion (without mention of abnormality of the bony pelvis), fetal distress, and dystocia without mention of underlying condition.

found that the statements on the certificates do not allow any significant, logical, or consistent distinction between these various forms of dystocia. Some of the conditions described in terms most commonly used on the certificate, such as transverse arrest, arrest of progress, and prolonged second stage, could be due either to persistent occiput posterior position, disproportion, non-dilation of cervix, etc. They might also, of course, be due to inertia, which is still kept as a separate title. The end result is that while the title "uterine inertia" is a fairly homogeneous group, some of the cases of inertia are in the miscellaneous group "other dystocia."

The tabulations have been made to show both an unduplicated count of cases with and without complications, and also, under *each* complication, all cases with that particular complication whether or not it was associated with some other. That is, any case with two distinct complications appears in the tabulation twice, once under each. In

general, it may be noted that there were two distinct complications in 15 per cent of the live births with complications, 31 per cent of the stillbirths, and 40 per cent of the maternal deaths.

Beginning with 1942, it was decided to allow for punching three complications for each case: two puerperal and one non-puerperal; and in addition, to provide for tabulating *all* distinct complications, however many there might be for any particular case. For all cases in which there are more than two puerperal or one non-puerperal complication, these as well as the other necessary data * are entered on index cards and, at the end of the year, added by hand to the machine tabulations.

CODING OF OPERATIVE PROCEDURE

All births have been classified into nine categories for operative procedure, as indicated in Table 2. Three of the

* Single or plural, full-term or premature, home or hospital, operative procedure, birth injury, age of mother, and number of previous live births and stillbirths.

Induction of labor, no other operation *	326	52	44	7

Not available separately in 1940-41

* The disparity in the relative incidence of induction of labor associated with stillbirths and with live births is, in very large measure, due to the fact that the stillbirth certificate, but not the certificate of live birth, contains a specific question regarding induction.

categories used in 1940 and 1941, low forceps, mid forceps, and "other operations," were further subdivided in 1942. A study of unpublished data by one of the authors elsewhere has shown that high forceps and forceps plane unspecified are associated with much much higher fetal loss than either low or mid forceps. As a matter of fact, in a 1 month sample run of the 1942 cards the stillbirth rates for both the former are ten times as high as the rates for low or mid forceps.

CODING OF OTHER MEDICAL INFORMATION

Congenital malformations and birth injuries of the infant (asked for on live birth certificates only) were merely coded "yes" or "no" in 1940-1941, but in 1942 are being coded by a simple one-column code, designed mainly to allow correlating by mechanical tabulation birth injuries with operative procedure and cause of neonatal death. For more detailed analysis, a handwritten card is made out for every case with a congenital malformation or birth injury, copying identifying information, physician's exact statement of nature of malformation and/or injury, physician's name, etc. These cards are used for the matching with the register of crippled children, and for detailed hand-tabulations of type of malformation, etc. The results of this matching for the 1940 births are shown in the 1940 Annual Report of the Division of Vital Statistics, and those for 1941 will be published shortly.

The code used for cause of stillbirth and the rules for treatment of joint causes are those developed by the U. S. Children's Bureau and approved by the Committee on Research and Standards of the American Public Health Association in 1940 for publication and trial in the United States. The tabulation and analysis of the 1940 stillbirths which appeared in the Annual Report

of the Division of Vital Statistics for that year give a measure of the degree of fallacy inherent in any system of selecting a preferred cause. For example, only 198 stillbirths in 1940 were charged to toxemia, while there were actually 391 or practically twice as many cases with toxemia stated as a complication; similarly, diseases in and accidents to the mother were charged with 101 of the stillbirths, but were mentioned as complications in 206 cases.

In coding the weight of the infant at birth, the following nine groups have been found most useful for our particular purposes:

I. *Non-viable* *prematures*

Less than 1,500 gm.; or 3 lbs., 5 oz.

II. *Viable* *prematures*

- (a) 1,500-1,749 gm. (3 lb., 5 oz.-3 lb., 13 oz.)
- (b) 1,750-1,999 gm. (3 lb., 14 oz.-4 lb., 6 oz.)
- (c) 2,000-2,249 gm. (4 lb., 7 oz.-4 lb., 15 oz.)
- (d) 2,250-2,499 gm. (5 lb.-5 lb., 7 oz.)

III. *Normal weight*

2,500-3,999 gm. (5 lb., 8 oz.-8 lb., 12 oz.)

IV. *Overweight*

- (a) 4,000-4,499 gm. (8 lb., 13 oz.-9 lb., 14 oz.)
- (b) 4,500-4,999 gm. (9 lb., 15 oz.-10 lb., 15 oz.)
- (c) 5,000 gm. and over (11 lb. and over)

TABULATIONS

We are confining the basic tabulations to a series of correlations of operative procedure with complications of pregnancy or labor, for eight specific groups each, of live births, stillbirths, neonatal deaths, and maternal deaths. While most of the births in New York State occur in hospitals, many mothers are still delivered at home; in 1941 they numbered 16,750, or 17.3 per cent. For this reason, as well as because of the recognized differences in home and hospital cases, this subdivision was added to the natural divisions into single and plural births, premature and full-term. Thus the tables correlating operative procedure with complications of pregnancy and labor are simultaneously specific for the three dichotomous classifications of plurality, gestation, and place of birth.

TABLE 3

With operative delivery	47.9	73.0	31.2	58.8
No operative delivery	48.8	47.6	19.3	19.0

* Stillbirths plus deaths under 1 month of age

By means of summary punch cards the basic tabulations are used as a source for numerous derivative tables combining live births and stillbirths, stillbirths and neonatal deaths, home, and hospital deliveries, etc. These combinations are obtained by the printing tabulator simultaneously for all the individual categories of operative procedures, with automatic controls and subtotals of any desired identifying categories. Another advantage of the summary cards is the ease with which the data can be accumulated and combined from year to year.

A few of the mortality rates are shown in Tables 3 and 4. It will be noted that while the fetal loss was practically the same for total home and total hospital deliveries, for cases with complications or with operative procedures the mortality rates were twice as high in home deliveries as in hospital deliveries. The same comparisons held for single full-term births only. The facts in detail, as well as an

analytical discussion of them which cannot be presented here, will be published in the near future.

Besides the tabulations for the entire area of the state, exclusive of New York City, detailed tabulations have been made showing for individual hospitals the births, stillbirths, and neonatal deaths, full-term and premature, and also the births by method of delivery.

This outlines the general procedure developed in the New York State Department of Health for handling the medical data on the birth and stillbirth certificates. In the time available for this paper, it is obviously impossible to consider details of procedure or present analyses of the results. It is hoped that this survey will furnish a basis for purposeful discussion here and elsewhere.

Supplemental Birth Certificate Information Used in Planning Crippled Children and Maternal and Child Health Programs*

AMY LOUISE HUNTER, M.D., AND
WILLIAM C. KEETTEL, M.D.

*Bureau of Maternal and Child Health, Wisconsin State Board of Health,
Madison, Wis.*

THE effectiveness of state health work depends on the strength of the local health organizations, while the effectiveness of the local health activities depends upon the interest and understanding of the health officials and their ability to apply health knowledge. In any state, or even within a county, problems will vary. Thus an important function of any state health department is to see that individual community problems are recognized and solved in the order of importance. Every available source of information must therefore be utilized in planning these programs.

Wisconsin is fortunate because of the close working relationship of the Bureau of Maternal and Child Health with the Bureau of Vital Statistics. Early in the days of the expanding maternal and child health program in Wisconsin it was necessary for the bureau to assign one of its staff to make special statistical studies. After training in vital statistics and public health education, this individual was transferred to the Bureau of Vital Statistics,

through which office current reports and special studies are prepared.

Birth certificates are extensively used by local public health nurses, especially in the demonstration programs. Early in the organization of any county work this resource gives the public health nurse information as to the proportion of deliveries done by doctors, and through direct contacts with them she obtains their coöperation in referral of prenatal patients for home contacts. In planning home visits special consideration is given to prematures, first born babies, or babies born to mothers who have lost several children. At one time special follow-up was indicated on any delivery not attended by a doctor. This, however, is no longer a problem, since more than 99 per cent of total deliveries in Wisconsin are by physicians.

THE PROBLEM OF INFANT BLINDNESS

The use of birth certificates as a means of obtaining additional information was not a new departure in Wisconsin. In 1909, by order of the State Board of Health the question—"Was silver nitrate used to prevent infant blindness?"—was placed on the birth certificate. In addition a rule was passed requiring that silver nitrate be

* Presented at a Joint Session of the Maternal and Child Health and Vital Statistics Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

used in the eyes of all new-borns. This made it possible for immediate follow-up on any cases where silver nitrate had not been used. Prior to 1909 at least one-third of the admissions to the schools for the blind were because of ophthalmia neonatorum, whereas now only rarely is a case due to this cause. Another indication of the effectiveness of this procedure was a recent survey of the entire state of Wisconsin (population 3,137,587) which showed only 10 cases of blindness among children under 5 years of age. Four of these were known to have been caused from injuries and 3 were due to congenital conditions. Ophthalmia neonatorum was proved as the cause in only 3 of the total cases—one, an Indian child born in 1939 who had received no prophylactic care. This one question on birth certificates thus played a very important part in solving the problem of infant blindness.

LOCATING PHYSICALLY HANDICAPPED CHILDREN

The second supplement was added to the certificate in 1917—"Was child deformed or physically defective? Yes, No, Nature of Defect." Since that time this information has been used to locate handicapped children. As the current certificates are filed, a copy of any showing a deformity or physical defect is made. Each month these are sent to the Crippled Children's Division in the Department of Public Instruction. In 1941 this source was responsible for 22 per cent of all the crippled children registered. Immediately upon receipt of these certificates a card is made up for the individual child, the color of the card varying according to the type of defect. Defects are thus sorted by color and filed by county. Each field worker then receives the names and all available information on individuals in the territory she serves. If there has been no indication that the child has

died, she writes, telephones, or makes a personal visit to the physician who signed the birth certificate. Such conditions as harelip, cleft palate, and club feet, which need early correction are immediately followed up, and the others as indicated. Usually the family physician requests the visiting staff member of the Crippled Children's Division to consult with the family directly and work out with them a plan for care. Exceptions occur in families of adequate means who prefer to make their own arrangements. In case the local public health nurse has not already made a routine neonatal visit, she is notified if any special demonstration of nursing procedures is needed.

PROBLEMS RELATED TO OBSTETRIC PRACTICE

Wisconsin in 1940 again sought the coöperation of physicians in obtaining additional information on birth certificates, with the hope that it might bring a better understanding of existing problems. The questions were worded to obtain information on complications of pregnancy and labor, prenatal care, test for syphilis during pregnancy, type of delivery, indications for operative delivery, and degree of fetal asphyxia. A statement indicated that this information would not become a part of official copies of the birth certificate. The former questions of illegitimacy, use of silver nitrate, and presence of deformity and type were included in this portion of the certificate. It was felt that this information would be of special value in helping local physicians to recognize their problems and to stimulate interest in their solution. The bureau also hoped to gain further information for effective program planning.

CODING AND STATISTICAL PROBLEMS

The first problem was the coding of this material. A detailed code was de-

vised by the Bureau of Maternal and Child Health which would include as much of this information as possible. The certificates are coded by a clerk assigned to the Bureau of Vital Statistics. Arbitrarily, all material is coded currently as stated, regardless of discrepancies which occasionally arise because the information is not written in the proper space or there are direct contradictions. As questions arise in regard to coding, the certificates are laid aside and several times each week these certificates are cleared with the obstetrical consultant.

Since the old form of certificate without the supplement was coded as "No data," this group was relatively high the first year. A few physicians failed to understand the value of these additional questions; however, letters to these doctors resulted in their coöperation. In 1941 incomplete certificates were less than 3 per cent of the total.

A second problem confronting the

bureau was the tabulation and analysis of this supplemental information. It was necessary to take into consideration the fact that the statistical staff were crowded with work and that facilities were limited. The first tabulations of the new material were considered a special study. However, the present and more desirable point of view is that these tabulations are a routine part of the analysis of birth certificate information.

Each item of the supplemental code is tabulated separately. This is very essential, for once the complete sorting is done, the material is available for combining into any form desired. Table 1 which lists the complications of pregnancy shows how this material can be combined. By early detailed analysis it was possible to eliminate certain items which rarely occurred and to add combinations which appeared frequently.

The statistical consultants of the

Children's Bureau offered valuable assistance in the simplification of sorting procedures. It is to be hoped that the experience of the states that have been using this supplementary information will be of assistance in drawing up a uniform code. A physician's handbook covering such a code would undoubtedly increase the accuracy of recording. It might encourage doctors to fill out the birth certificate themselves rather than depending upon the obstetrical floor nurse. This practice was brought to light by examining certificates from certain large hospitals where almost exact uniformity was noted.

USE OF MATERIALS IN PROGRAM PLANNING

The primary contribution of the supplemental material is to obtain obstetrical morbidity information which previously had not been extensively available. From morbidity and mor-

tality data fatality rates can then be determined, and over a period of years it is hoped that trends may be obtained that will measure the effectiveness of the educational activities. When uniformly coded and tabulated it will be possible also to compare obstetrical results in various sections of the United States.

The actual uses of this material and some of the early results are interesting. One of the first items extensively used was the information on operative deliveries, particularly the information on cesarean sections. Previously the bureau had undertaken an extensive study of this subject and for a number of years had sent out an elaborate questionnaire to physicians on all cases where death followed cesarean section. Questionnaires were also sent to all hospitals and maternity homes to determine the number of hospital deliveries and sections. There was a 100 per cent return from the 225 hospitals and

TABLE 2
Indications for Cesarean Section
(Wisconsin 1940-1941)

maternity homes licensed for obstetrical care. In 1934 there were 868 sections performed in the state, while in 1939 there were 1,221 sections. The number of cesarean sections reported from the birth certificates showed 1,439 sections for 1940 and 1,577 sections during 1941. These 1940 and 1941 figures correspond very closely with the number obtained by the more laborious and less accurate method of direct questionnaires.

Additional information was also made available as to type and indication for section. In 1940 we found 86.4 per cent of the sections were of the classical type, 13.1 per cent were low cervicals, and 0.5 per cent were of the radical type. This contrasts with the 82.4 per cent classical sections, 16.2 per cent low cervicals, and 1.3 per cent radical type shown in 1941. The downward trend in classical sections and the slight increase in the low and radical

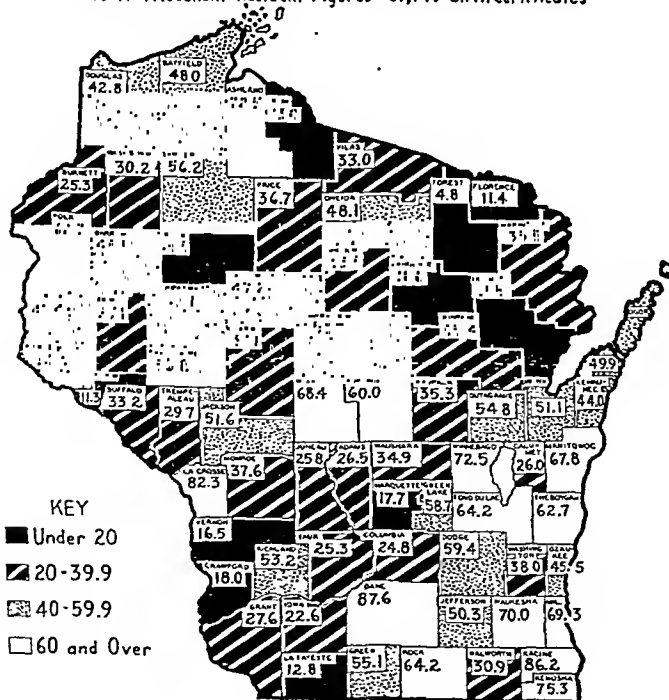

type of section may in part be due to the intensive postgraduate approach to this problem. The indications given for cesarean sections are listed in Table 2. Information of this type will be of great value in observing future trends.

Recent developments very clearly show the value of gathering all available information on births and using this constantly in program planning. As a direct result of the presentation of cesarean section data at the Medical Society meeting in Wisconsin a year ago, local physicians have initiated studies and discussions in their own communities. In certain instances hospital staffs have set up regulations requiring consultation prior to any major obstetrical operation. Several leading obstetricians have presented additional material on cesarean sections and emphasized the responsibility of the medical profession toward such problems. Favorable changes are definitely oc-

FIGURE 1

WAS MOTHER'S BLOOD TESTED FOR SYPHILIS?

1941 Wisconsin Resident Figures - 57,749 birth certificates

curing as a result of tangible information properly presented to the medical profession.

When this supplemental information is tabulated by county, it stimulates the spirit of competition which so frequently seems to further health programs. An example of this is the use of material on the test for syphilis. This information when tabulated by counties as shown in Figure 1 reveals a range from 4.8 per cent to 87.6 per cent in the use of prenatal Wassermanns. When such maps are shown at medical meetings physicians in those counties having the low rates, which show up as black on the map, immediately want to improve their record. The question as worded on the birth certificate—"Was mother's blood tested for syphilis?"—may be confusing as some certificates indicating "yes" definitely stated that this was the premarital Wassermann test which is required in Wisconsin. These maps have also been used in individual contact work with physicians and in postgraduate medical programs. One interesting comment of physicians on this question has been their statement that they have used it to encourage reluctant patients to accept the procedure by stating that the State Board of Health requires them to report it on the birth certificate. After such statement a patient rarely refuses.

Information on prenatal care is considered inadequate. The question as worded—"At what period of pregnancy did patient first consult you?"—gives insufficient information. Undoubtedly some of the early contacts are made for diagnosis and the physician may be seen only infrequently during the intervening months. A further question asking for total prenatal visits would be valuable in estimating the adequacy of prenatal care. The significant point revealed is that among the Wisconsin births in 1941 only 4.1 per cent re-

ceived no medical supervision during the prenatal period, and that in 50.3 per cent medical contact was made during the first trimester of pregnancy.

Trends are apparently changing to earlier prenatal care as indicated by the reports of physicians mentioning the effectiveness of educational programs in bringing expectant mothers to them earlier.

Now for the first time statistical information is available which in spite of limitations may over the years give more tangible evidence of progress. It will make possible comparative studies showing how early prenatal care influences the various complications of pregnancy and labor.

More detailed information on prematurity and its relation to complications of pregnancy and delivery, as well as to asphyxia at the time of birth, is available through this source. By special tabulations it has been possible to present county information on prematures born at home and in hospitals. This facilitates allocation of incubators and encourages their use by doctors.

Supplemental birth information has been of great value in planning programs for postgraduate medical education. During the year there have been opportunities for presenting to the medical profession the fact that toxemia is the leading complication of pregnancy, and that prolonged labor is the most frequent complication of labor. As a result, these problems were given a most prominent place at the recent State Medical Society meeting. Tabulations of all supplemental information by counties has proved very useful in presenting local problems to the county medical societies. Interest is stimulated in their own problems and obstetrical results.

While decreases are to be expected in the leading causes of obstetrical morbidity and mortality, there may be unavoidable setbacks in the years im-

mediately ahead because of the present world situation. In these pressing times the supplemental birth certificate material offers a new source of readily available information. Each certificate is a briefly summarized obstetrical history from which may be obtained information concerning obstetrical morbidity. Over a period of years, trends will be

available to check progress made in meeting specific problems. In order to be of the greatest possible value there should, however, be uniformity in coding and classification. Every director of public health activities should find supplemental birth data of value in program planning, provided it is properly used and interpreted.

Bottlenecks in Our War Nursing Program*

ALMA C. HAUPT, R.N., F.A.P.H.A.

*Executive Secretary, Subcommittee on Nursing, Health and Medical Committee,
Federal Security Agency, Washington, D. C.*

"TIME is short" for the nursing profession to undertake the tremendous adjustments called for if it is to make its maximum contribution to this war. "Time is short" for us to review our programs and break the bottlenecks that slow down or even stop our progress.

Today public health nurses have the opportunity and the responsibility of exerting every ounce of leadership they possess. Courageous leadership is needed throughout the nursing profession. It is needed in our relations to the fields of public health, medicine, hospital administration, nutrition, education, and social work. It is needed in relation to the public, the family at home, the worker at work, the citizen as a member of an organized group, the voter at the polls, and it is needed with relation to the various branches of national, state, and local government.

Before this leadership can be exerted effectively, we must have first, a clear picture of the total war nursing program; second, we must be completely objective in analyzing the bottlenecks in the program; and third, we must be determined to break the bottlenecks and get proper action.

At the risk of oversimplification, I would say that our war nursing pro-

gram consists of four parts: (1) increasing the supply of students; (2) greater use of auxiliary workers both paid and volunteer; (3) finding and distributing graduate nurses equitably for maximum war needs; (4) provision of proper working conditions in terms of hours, wages, and living conditions. No one of these four points of the program can assume greater importance than the other if satisfactory progress is to be made.

Unprecedented demands upon graduate nurses from the armed forces and civilians alike make it necessary to provide a reservoir of potential graduate nurses by increasing the number of students in schools of nursing. Taking cognizance of the seriousness of the situation, Congress made available on July 1, 1941, the first federal aid for nursing education. The sum of \$1,250,000 was appropriated for this purpose to the U. S. Public Health Service. Later a deficiency of \$600,000 was granted, and on July 1, 1942, the appropriation was increased to \$3,500,000.

The 1943 goal of 65,000 new students in schools of nursing is an increase of 10,000 over the 1942 goal. An analysis of the spring classes indicates that this goal is not being met. Actually, the 65,000 quota for new students represents the present training facilities of schools of nursing rather than the true needs of the country. If

* Founded on a paper presented before the Public Health Nursing Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

schools were able to handle the number of new students necessary to meet nursing shortages, the quota would be set at 84,000 for the year beginning July 1, 1943.

What are the bottlenecks to student enrollment?

One is public understanding. Here is a rich field for the public health nurse in her contacts with the lay public. You, better than anyone else, can help prospective students to overcome parental objection.

Monetary rewards are also a major problem. If college and high school girls can go immediately into war work at a good salary, why should they spend two to three years in nursing without salary except in the form of living expenses? To counteract this situation, we have tuition scholarships available through the U. S. Public Health Service programs, and the National Nursing Council for War Service is raising a large National Scholarship Fund. However, it may be necessary to go further and provide some sort of reimbursement to students preparing for war nursing.

We face also the question of accelerated courses. Here again we have bottlenecks—first, in our resistance to the idea. Perhaps if we study carefully the recommendations prepared by the National League of Nursing Education and see how acceleration can be effected soundly, our resistance will break down. The National Nursing Council for War Service recommends that for high school students, theoretical courses in nursing be completed in 30 months, and for college students in from 24 to 28 months, depending on their backgrounds and achievement.

Suppose we find and bring back into service every graduate nurse; suppose we meet our quotas for student nurses; even that will not be enough! We must develop an active program for preparing and employing auxiliary workers. This

is chiefly a problem for each local hospital and health agency. Nationally, the program for volunteer nurses' aides is administered by the American Red Cross in coöperation with the Office of Civilian Defense. Here again, public health nurses are in a strategic position to awaken public interest and to encourage agencies to plan for the wise use of these available helpers.

With the realization that competition from industry and uniformed military auxiliaries is making our quotas increasingly difficult to reach, many members of the nursing and medical profession have presented suggestions for a remedy. These have gone through the mill of committee meetings. The outcome has been the Student War Nursing Reserve, which was approved by the Health and Medical Committee on January 26, 1943, submitted to the U. S. Public Health Service, and is now being considered by Congress in the form of the Bolton Bill.

This plan attempts to meet the competition in two ways, namely, by providing a new appeal and by financial rewards. The appeal is in the setting up of a distinctive corps with rank, insignia, and, possibly, street uniforms. The financial rewards include maintenance, tuition, and a modest monthly stipend for personal expenditures. The proposal is that the government share with the schools of nursing in these costs.

It is important to mention that the Student War Nursing Reserve Plan includes provision for the acceleration of the basic course to either 24 or 30 months. This leaves each school of nursing free to make such plans for acceleration as fit into its local situation. Whereas acceleration presented a difficult adjustment at first to nurse educators, the swift change in public psychology, in educational practices in other fields and in the course of the war will undoubtedly win many schools

of nursing over to instituting the fastest and soundest type of acceleration consistent with the proper care of patients. Where state laws permit, the nurse who has completed her theory might be graduated. She can then apply for a full-time job in the military or appropriate civilian services. If she has omitted certain specialties in her accelerated program, and cannot graduate, some plan should be worked out for her to make up these deficiencies when the war is over.

For students in their senior year who have completed their theory, it is proposed to arrange affiliations in Army, Navy, governmental and civilian hospitals upon the approval of the parent school. It is further proposed that these students, known as "cadet nurses," receive a modest stipend and in addition, because it will be necessary for them to live outside of the hospital, receive from the hospitals the difference up to possibly three-fourths of the salary of a graduate nurse. In these proposals, there is frank admission that student nurses serve while they are learning.

Letters pour in to government offices protesting that many other types of students are paid by the government for their education, whereas nurses give service while learning, pay a tuition, and get no wage. Let us once and for all differentiate between nursing education and nursing service to patients. For the latter, let us agree that the student nurse be paid, and come to a conclusion as to whether the government, the hospitals, or both should foot the bill.

Greater use of auxiliary workers appears to be the only immediate solution to the problem of overcoming the lack of facilities for training additional new students. As a pattern for this phase of the program we have the pioneer work of the American Red Cross, together with the recently de-

veloped activities of the Office of Civilian Defense. Suggestions for making the best use of volunteer participation are to be found in *Volunteers in Health, Medical Care and Nursing*, which may be procured from the Office of Civilian Defense, Washington, D. C.

Before a health department or hospital expands its use of auxiliary workers or volunteers, a critical analysis should be made of jobs done by professional workers for the purpose of ascertaining what duties can be delegated with safety to non-professional people. Agencies that have not made such studies and allocations of jobs are urged to do so immediately.

Reports are still being received which show that graduate nurses in some hospitals are serving trays, filling water glasses, and cutting flowers. In some health departments, graduate nurses trained at considerable expense in the specialty of public health, consume precious time and skill in doing clerical work, making dressings, and serving as receptionists. Critical nursing shortages cannot be met if such waste of nurse power continues.

To supply and distribute graduate nurses equitably for maximum war needs, both military and civilian, we need first to have in each community some central place where the name and pertinent data about each of the estimated 400,000 nurses of the country are assembled. In 1941, our national survey reported some 300,000 graduate nurses—one bottleneck was revealed when it was found that some 100,000 nurses, mostly those retired or inactive—did not reply. That was before Pearl Harbor. In January, 1943, a new post card survey was undertaken by the U. S. Public Health Service working with the national, state, and local Nursing Councils for War Service.

Concurrent with a survey of available supply, should go a study of the

nursing needs in the community. For this purpose, the National Nursing Council for War Service has published *A Guide to the Distribution of Nursing Service During War*. Has your local nursing council used this guide? If not, that is a bottleneck. Of what good is to know where the nurses are unless we know where they must be used? We know that the armed forces will need 66,000 nurses by the end of 1944. We know their needs may go far beyond that number and that they have priority. We know also that government hospitals and public health services, supplied through the U. S. Civil Service Commission, need several thousand nurses. How can these demands be met, and at the same time maintain a reasonable, local, civilian nursing strength? Part of the answer is for each locality to analyze the total nursing situation, to eliminate all duplications, promote economies of nursing time, and utilize to the fullest auxiliary nursing personnel.

It is urgent that we think also of the nursing needs of the new communities and new industries arising out of the war situation. Many of them have no organized care of the sick; some may have as yet no health departments. In nursing we have well accepted patterns for organizing, administering, and financing local nursing service. Each state Nursing Council for War Service should work with its state health department in planning for a proper distribution of nursing service wherever it is needed.

Then comes a tough problem—that of fitting the right nurse to the right war job. For this, the National Nursing Council for War Service has issued *Priorities for Nurses*. Have you read it? If not, that is a bottleneck.

To put these priorities into effect is now our major problem. We are doing everything we can to make the voluntary system work. But the National

Nursing Council feels the need for whatever financial assistance, moral suasion, and authority the government has, and recommended that a Nursing Supply and Distribution Unit be set up under the War Manpower Commission. The purpose of the Unit, as the name implies, is:

1. To determine the availability of nurses for service in the war emergency.

2. To aid in the equitable distribution of nurses so that the nursing needs of the armed forces and of civilians will be adequately met. This distribution will be on a voluntary, not a compulsory, basis.

Finally, we come to the fourth point of the program—that of good working conditions for students, graduates, and auxiliaries. Civilian hospitals are now confronted with a new type of competition, for the Army and Navy pay bill provides nurses with \$150 a month. For some time, the Civil Service Commission has paid junior nurses \$1,620 a year and staff nurses \$1,800. Government salaries for nursing are thereby setting a precedent for the private hospitals to consider as one factor in attracting and maintaining staff.

Hours of work, incentives for advancement, provision for sickness and old age retirement, opportunities for recreation, appropriate living quarters, and good food are some of the other requirements of good personnel policies.

Just one word about the housing of nurses. Emphasis is being placed on letting faculty and senior students live outside of the institution in the community. What we need increasingly is the community viewpoint with regard to nursing. We need to see the patient in relation to his family and his environment. But try as we may to develop that point of view, residence in dormitories seems to have blinded many of our best and most promising faculty and students. The housing shortage may be a blessing in disguise, for living in the community will undoubtedly give

nurses a change in scenery, get them away from rehearsing the day's professional events, and broaden their interest in community activities.

Perhaps one of our major bottlenecks is that we have let nursing be divided into too many tight compartments. Today we must see nursing as a whole. The best way to do this is to lend every support to our state and local Nursing Councils for War Serv-

ice. Through them should come the answers to the distribution of graduate nurses, the increase in the supply of students, and the use of auxiliaries. Through them you make your contacts with the National Nursing Council for War Service and the government's Subcommittee on Nursing. Through them, you may show what leadership public health nursing is able to exert in wartime.

Epidemiology of Pneumococcus Pneumonia

A Study, Including Bacteriological and Serological Observations
in a Rural Community during a Season of High Incidence *

EDWARD S. ROGERS, M.D., M.P.H., F.A.P.H.A., ANNE M.
BAHLKE, M.D., M.P.H., AND ALBERT H. HARRIS II,
M.D., F.A.P.H.A.

*Bureau of Pneumonia Control and Division of Laboratories and Research,
New York State Department of Health, Albany, N. Y.*

BETWEEN January 11 and May 1, 1940, a study was made of the incidence of pneumococcus infection in a sample population in Northville, Fulton County, N. Y. Northville is a relatively isolated village which, at that time, had a population of 1,111. Just prior to the start of the investigation an unusual incidence of Type 1 pneumococcus pneumonia had been noted in

this particular vicinity (see Table 1, A and B).

The sample population was random on a geographical basis, alternate households within the village being enrolled for study. That the sample was well selected is borne out by close correlation in sex and age distribution between it and the population of the village at large as recorded in the 1940

* The figures are given for July to July so that all the cases that occurred in any one "pneumonia season" will appear together.

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-First Annual Meeting in St. Louis, Mo., October 29, 1942.

census. The group was surveyed 4 times in all. The first survey, during which the enrollment was made, con-

sumed approximately 6 weeks (January 11–February 18). Subsequent surveys were accomplished in 3–4 weeks each (February 19–March 13; March 14–April 2; April 3–May 1, respectively). Seventy-eight households comprising 271 individuals were enrolled in the initial survey. Seventy-four households with 259 individuals remained under observation throughout the study period.

At the first interview, identifying data were obtained for each member of the household and further facts of possible significance such as general health, known contact with pneumonia, and gregarious activities were noted in detail for the 30 day interval immediately preceding the interview. At each subsequent survey these data were brought up to date.

Also, at each survey, cultures were made from the pharynx and nasopharynx of the individuals in the study group. One swab was passed thoroughly over the pharyngeal wall and tonsils or tonsillar fossae. Another was introduced through each nostril into the nasopharynx until it touched the posterior nasopharyngeal wall. In this position it was rotated gently against the membranous surface. Both swabs were combined in a tube of blood broth and incubated at the field laboratory which was set up in the central school in Northville. In no case did an interval of more than 3 hours elapse between culture and incubation. This laboratory was equipped and staffed to examine the cultures for the presence of pneumococci of all types. Whenever these microorganisms were isolated they were typed according to the Cooper classification.

The details of the bacteriological technic briefly were as follows:

Culture media included (1) beef infusion broth with 1 per cent dextrose and 5 per cent horse blood, (2) beef infusion broth with proteose peptone and 0.02 per cent dex-

trose, and (3) blood agar plates. After the blood broth cultures had been incubated for approximately 6 hours at 35° to 37° C., a mouse weighing from 18 to 22 gm. was inoculated intraperitoneally with 0.5 ml. of the culture, and a blood agar plate was streaked. Mice that lived overnight were subjected to peritoneal puncture, and the aspirated exudate was examined by the Neufeld technic with Type 1 serum only. Mice that died were autopsied and the peritoneal exudate was examined for all types directly by the Neufeld technic. In addition, the exudate and heart blood were cultured on blood agar which was then incubated for 18 to 24 hours. If the type had been previously determined, the typing was confirmed with the homologous anti-serum by the examination of a suspension of colony fishings picked from the plate; otherwise a complete examination was made to determine the type. Whenever the examination of colonies which were morphologically characteristic of pneumococci failed to reveal a type, solubility tests were undertaken with a 1 per cent solution of sodium desoxycholate and all soluble strains were saved for further study at the central laboratory in Albany. Mice that lived were sacrificed and autopsied approximately one week after injection, and the peritoneal fluid and heart blood were examined as described. The possibility of the occurrence of more than one type of pneumococcus was always borne in mind.

During the second survey and again in the fourth, blood specimens were obtained from a large number of the study group. These specimens were analyzed by mouse protection tests for Type 1 pneumococcus antibodies.

One-tenth ml. of serum was tested in white mice with different doses of a highly virulent 16 hour broth culture of the standard strain. The minimum lethal dose was determined in each test according to the standard method, and the estimate of the protective activity was based on similar results in at least two tests.

During the study period 7 cases of pneumococcus pneumonia developed in the Northville area. These were made the subject of separate investigation. Three of these cases occurred among households enrolled in the study group. However, only the culture results obtained at the regular surveys are in-

* Each type found in a single individual is tabulated separately, making a total of 254 strains of pneumococci among 167 individuals positive for pneumococci.

cluded in the analysis of the carrier status of the sample population. Thus, although there were three known Type 1 cases in the study group none of them happened to harbor Type 1 pneumococci at the time of survey and these three therefore do not appear in the tables concerned with the incidence of pneumococcus infection in the sample population as determined by culture survey technic.

As the term "pneumococcus infection" is used in this paper, it denotes the presence of pneumococci detected as the result of pharyngeal or nasopharyngeal culture or sputum examination, regardless of whether or not the

individual concerned was a pneumococcus carrier in the usual restricted sense of the word, or a case of pneumococcus pneumonia.

Of the 267 individuals from whom cultures were taken, 248 of them at all four surveys, 167 (62.5 per cent) were found to be pneumococcus carriers at some time (Table 2). Pneumococcus Type 19 occurred in 12 per cent, Types 1 and 3 in 9 per cent, and Type 11 in 6.7 per cent of the study population. One hundred individuals carried only one type. Sixty-seven (40 per cent) of those positive carried more than one type; 52 had 2 types; 12, 3 types; 1, 4 types; and 2, 5 types simultaneously.

In general, types detected in a given individual did not show much tendency to persist (Table 3). Of 254 strains recovered in the study group, 198 (78 per cent) were recovered only once, 48 (19 per cent) twice, 7 (3 per cent) three times, and only 1 strain four times from the same individual. Types encountered more than once in a given individual occurred twice as frequently in consecutive cultures as they did intermittently.

The proportion of pneumococcus carriers of all types detected was con-

sistently higher for males than females in all age groups (Table 4). This is compatible with the findings reported by Gundel and Okura¹ and by Ardelean.²

Of a total of 1,061 cultures in the sample group 287 (27 per cent) were positive for pneumococci (Table 5). For the first 7 weeks of the study the proportion of positive cultures remained quite constant. The subsequent irregularity and the high peak of the 9th week during which 60.6 per cent of the cultures taken were positive, remains without a satisfactory explanation. All controllable factors were apparently kept constant. No single pneumococcus type assumed predominance. The age distribution of those cultured during this week was essentially the same as for the total study group. There was no relation to particularly unfavorable weather conditions. The incidence of acute respiratory infection did not change appreciably, nor was there any other form of illness prevalent, with the exception of a small number of cases

of an acute gastrointestinal disturbance the occurrence of which, however, seemed to bear no constant time relationship to the incidence of pneumococcus infection. Furthermore, it will be seen from Table 6 that there appears to be no correlation between the occurrence of either acute upper respiratory infection or gastroenteritis and the incidence of pneumococcus infection in the study population as a whole.

The incidence of pneumococcus infection of all types encountered in households at each of the four surveys does not show appreciable variation (Table 7) but Type 1 appears to have been somewhat more prevalent after the first survey.

Seventy (89.7 per cent) of the 78 households in the sample population harbored one or more infected persons, in this instance all carriers, at some time during the study (Table 8). In approximately 20 per cent of these the same type occurred simultaneously in two or more individuals and in 26 per cent the same type was recovered at

Adults and Children	41	40	12	97.6	29.3

different surveys. Type 1 was encountered in 14 (17.9 per cent) of these 78 households.

Recent studies of pneumococcus carriers by Stebbins,³ Mackenzie,⁴ and Smillie,⁵ have indicated that children seem more susceptible to infection than adults, and it has been further shown by one of us⁶ that they play an important rôle in the dissemination of pneumonia. The relatively small difference in the incidence of pneumococcus infection of all types in households with or without children of school or preschool age becomes marked if Type 1 is considered alone (Table 8). This type occurred in 29.3 per cent of the households with children and in only 5.4 per cent of those composed exclusively of adults of 20 years or older. This observation is consistent with the finding already mentioned that the major portion of those with Type 1 infections are under 10 years of age. The numbers of children of school and preschool age were too small, however, to permit separation, as was attempted by Mackenzie,⁴ of the effect of age

per se from the effect of school contacts as a factor closely linked with age.

As stated, at each survey careful inquiry was made into the activities and close personal contacts of each subject. In the following analysis contacts are defined as "household" to mean persons residing permanently with the family group in question, and as "extra-household" to mean individuals who were not in residence but had a minimum contact of a close nature with the person in question on the average of at least 1 hour a week.

As a collateral study to that of pneumococcus carriers in the sample population, cultures and contact histories were taken from all household and discoverable extra-household contacts, as defined, of known cases of pneumonia in the town and its immediate environs. These data were collected on 49 contacts of 8 cases of Type 1 pneumococcus pneumonia, and among these 49, 10 persons (20.4 per cent) were found infected with Type 1 on immediate or subsequent culture (Table 9). This group, while not strictly comparable,

TABLE 9

¹ Three individuals had contact with both a case and a carrier, but each of them appears only once in this table, their position being determined by the nature of the contact known to have occurred first. On this basis, 2 are in the case contact group and 1 in the carrier contact group.

² This figure is comprised of 7 pneumococcus carriers and 2 primary cases which occurred during the course of the study in the random population sample. One carrier who gave a history of contact with one of these 7 but not with any of the primary carriers or cases is not included in the 9 positives but is in the total 48.

³ The third case of pneumococcus pneumonia occurring in the sample population appears here.

had a rate of contact infection no greater than that for Type 1 infection among the household and extra-household contacts of 11 known index Type 1 carriers. There were 56 contacts of these carriers among whom 13 (23.2 per cent) were found to be infected in the course of the culture surveys subsequent to their initial known contacts.

Both of these rates stand in sharp contrast to the incidence of Type 1 infection in the 198 members of the study population who had no known contact with either case or carrier of Type 1 and among whom 13 (6.6 per cent) became infected either as a case or carrier of this type. It is not presumed that this latter group was free of contact but it does seem reasonable to assume that the duration and intimacy of contact was probably much less than that in the other two groups. These findings tend to corroborate the view that the duration and intimacy of contact with infected persons is an important factor in the spread of pneumococcus infection.

The records of previous known pneumococcus pneumonia in Northville are unfortunately incomplete, but it is known that Type 1 pneumonia had occurred at least once in 1935 and twice in 1938. Pneumonia due to Types 3, 4, and 5 had also been reported during the 5 years prior to the study. In so far as can be determined, however, there had been no occurrence of any of these types beyond that consistent with their endemic levels.

It is unfortunate that no baseline study could be made of the blood antibody levels of the population prior to the onset of the high incidence of Type 1 pneumonia that occurred during the 1939-1940 season. However, if the general observations of Finland⁷ and the studies of Felton⁸ on 281 normal persons can be accepted as reasonably applicable to Northville, the levels of protective antibody found upon titration of the sera of 161 persons from the Northville study group (Table 10) indicate either that the population of Northville had previously had considerable exposure to Type 1 infection or that the infection was currently far more prevalent than suggested by the 9 per cent incidence rate for Type 1 pneumococcus in the sample population obtained by culture methods.

Of 161 individuals studied, 58 (36.0 per cent) showed protective antibodies in the blood at significant levels of 100 m.l.d. or greater. Forty-four (27.3 per cent) showed levels of 1,000 m.l.d. or greater, which suggests the likelihood of relatively recent type specific immunizing experience. Such a possibility seems plausible inasmuch as 2 cases of Type 1 pneumococcus pneumonia and 1 of Type 1 pneumococcus meningitis were known to have occurred just beyond the environs of the village, and 3 cases of Type 1 pneumonia had occurred within the village limits during the 6 weeks preceding the start of the survey.

One hundred and forty-five individuals were tested twice, the first

serological survey being made during the second culture survey and the second serological survey during the fourth culture survey. The trend of antibody level from the first survey to the second suggests that the basic level of exposure remained fairly constant during the study period (Table 11). Nineteen (13.1 per cent) of the sera

serological examinations. All of these had an antibody titer of 100 m.l.d. or more (Table 12). Of 48 individuals who had a history of contact with known Type 1 carriers or cases, 27 (56.3 per cent) had a titer of 10 m.l.d. or less, and 21 (43.8 per cent) 100 m.l.d. or more. All of these people had known exposure and it is reasonable to assume that many of

showed an increased titer, while 26 (17.9 per cent) showed a decrease. Among the 11 persons twice tested who were known to have or have had Type 1 pneumococcus infection, 4 increased and 4 decreased between the two surveys.

There were 12 known carriers and 2 cases of clinical Type 1 pneumonia among the 161 individuals who had

them became carriers at some time even though the infection was not demonstrated bacteriologically. This assumption is borne out by the considerable proportion (43.8 per cent) who had mouse protective antibody levels of 100 m.l.d. or more. In contrast to these are the 99 individuals who had no known contact with a source of infection. As previously stated it is not assumed that

the members of this group did not have contact but it is assumed that their total contact experience was less than that of the so-called "known contact" group. The protective antibody levels among those without contact in which 76.8 per cent had only 10 m.l.d. or less are consistent with this view and it seems likely that had it been possible to have used a finer scale of antibody titration the contrast between the "known contact" and "no known contact" groups would have been greater.

There was little evidence that infection with a heterologous type of pneumococcus appreciably increases the antibody titer for Type 1 (Table 13). All individuals with Type 1 infection found upon culture showed a maximum protective Type 1 antibody titer of 100 m.l.d. or more whereas but 29.6 per cent of the persons found infected with types other than Type 1 showed maximum protective Type 1 antibody titers of 100 m.l.d. or more, and there is ample reason to believe that some of this latter group carried undetected Type 1 infection.

As has already been seen, no single pneumococcus type assumed preponderance at any time (Table 5 and Chart 1). Seven cases of pneumococcus pneumonia (3 Type 1; 1 mixed, Types 1

and 19; 2 Type 16; and 1 Type 7) occurred in the area during the study period (Table 1 and Chart 1). The ratio of cases of Type 1 pneumonia to known carriers of this microorganism was 1:8. Or, if we assume that a Type 1 antibody titer of 100 m.l.d. or greater constitutes evidence that the individual had been a case or carrier relatively recently, then the ratio of cases to these implicit and explicit carriers becomes 1:19. In previous studies of Type 1 pneumococcus distribution in rural areas at Treadwell³ and Schuyler Lake⁴ 2 cases were noted to 32 known carriers (a ratio of 1:16) during a 2 months period in the former area, while in the latter, which probably is not strictly comparable, there were 5 cases to 63 carriers (a ratio of 1:13) for the entire observation period of 14 months. The question of lack of comparability here resides in the possibility that there was selection of individuals for repeated culture on the basis of their known exposure, whereas the Northville data are based upon the results of the four surveys only. The fact that the figures involved are small in every instance, that the seasons and time intervals are not identical, and that one case more or less would make an appreciable difference in the case-to-carrier ratio seems to

CHART I
SHOWING DISTRIBUTION OF POSITIVE CULTURES AND THREE MOST COMMON TYPES BY WEEK OF CULTURE

provide sufficient basis for the relatively small differences in these 3 ratios. They constitute interesting refutation of the prevailing opinion, apparently unjustified, that there is a marked tendency for Type 1, 2, or 5 pneumococcus infection to incite pneumonia in a normally susceptible population rather than to remain harmlessly localized in the upper respiratory tract.

CONCLUSIONS

1. The spread of pneumococcus infection in a community, in so far as it is dependent on person-to-person contact, seems to be governed equally as much by contact with healthy carriers as by contact with the clinical disease.

2. Consideration of the case-to-carrier ratio in this and prior similar studies suggests that the so-called invasive types of the pneumo-

coccus, of which Type 1 is the prime example, are probably not as invasive as hitherto thought, and perhaps no more so than several other types less commonly encountered.

3. In the presence of an abnormal incidence of pneumococcus infection, large numbers of people may acquire type-specific antibodies at what may be assumed to be significant, and in some cases perhaps even protective, levels without having had any signs or symptoms of clinical disease.

4. The immunological data suggest that the culture methods in current usage do not give an accurate picture of the prevalence of pneumococcus infection in a given population group.

5. Further evidence appears in this study to favor the now generally accepted view that healthy carriers occur with appreciably greater frequency in the younger age groups. Whether this is due to actual differences in susceptibility at the different age levels, or to the gregarious peculiarities of the life

of the younger individuals could not be ascertained.

6. The apparently greater tendency of males to become carriers of pneumococci of all types as noted here has seldom been recorded previously in the literature. The numbers in the present study are too small for the figures to be conclusive, but should this difference prove to be a true one, it would be of particular interest in the light of the recognized greater incidence of clinical pneumococcal disease in males.

7. Although the occurrence of type-specific pneumococcus infection in a given population is a prerequisite to the spread of clinical pneumonia of the same type, the presence of such infection is not the sole determining factor in the selection of those individuals who develop the clinical disease. The probable significance of numerous other factors such as the virulence of the invading pneumococcus and variations in host resistance, is well recognized, but a true understanding of many of them is still wanting and knowledge of the manner in which they actually operate is relatively meager.

NOTE: A study of this nature necessarily involves the coöperation and assistance of many persons. The authors are particularly grateful to the people of Northville for the manner of their reception, and to Dr. J. Edward Grant, Health Officer, Dr. K. André Durand, School physician, and Harold Boulton, Principal of the Northville Central School, which housed our laboratory and aided in innumerable ways.

The field team consisted of Dr. Anne M. Bahlke; Emma MacChesney, Helen Bosworth and Beatrice Weaver, public health nurses; and Kathryn Smith, Lillian Stehr, and Dorothy Crary, laboratory technicians.

The serological studies were conducted under the direction of Jessie Hendry.

Grateful acknowledgment is also made of the constant interest and helpful advice of Drs. George H. Ramsey, Ernest L. Stebbins, and James E. Perkins, and for the statistical assistance of Isabel McCaffrey.

Improved Technic for Isolation of Dysentery Bacteria from Stools by Formaldehyde Inactivation of Bacteriophage

I. J. KLIGLER, PH.D., F.A.P.H.A., E. OLEINIK, AND I. CZAZKES

*Department of Hygiene and Bacteriology, Hebrew University,
Jerusalem, Palestine*

DESPITE successive improvements of culture media, the laboratory diagnosis of bacillary dysentery remains unsatisfactory. Laboratory workers repeatedly fail to obtain cultures from stools of typical cases of clinical dysentery. The primary reason for this failure appears to be the age of the stool; stools cultured shortly after they are voided give better results than when culturing is delayed. A possible explanation of the extreme lability of the dysentery organisms is the presence of specific phage in the stool. The frequency of the presence of such phage has led Wheeler and Burgdorf (1941) to suggest its detection as a diagnostic procedure; this was not feasible because dysentery phage is often present also in normal stools. However, the fact that dysentery phage is of common occurrence in stools suggested that the rapid death of dysentery bacteria in stools was due to lysis. Assuming that to be the case, it would follow that an agent which would inactivate phage without injuring the bacterial cells should, when added to the stools, greatly increase the chances of isolating the causative organisms.

The work of Schultz and Gebhardt (1935) and of Kligler and Oleinik on the inactivation of phage by small doses

of formaldehyde indicated that this chemical might serve the purpose. The data presented below show that the simple procedure of adding to fresh stools a concentration of formaldehyde too low to injure the cells, but sufficient to inactivate phage, resulted in a considerable increase of positive cultures.

In preliminary experiments phage was added to stools artificially inoculated with shigella. In 6 hours the inoculated organisms could no longer be recovered. However, this killing effect was inhibited or prevented by the addition of an appropriate concentration of formaldehyde. The following is a typical experiment: 10 gm. of stool from a normal individual, proved not to contain phage, were emulsified in 10 ml. of saline and infected with 2 drops of a broth culture of Shiga dysentery bacteria. The stool was divided into two portions. To one part phage was added at the rate of 0.5 ml. of broth to each gm. of stool. To the other part no phage was added. Each sample of stool was then subdivided into equal parts and various concentrations of formaldehyde were added. Cultures were made immediately and 6 and 24 hours later; during the interval the stool samples were kept at room tem-

peratures. Cultures were made on MacConkey plates and suspicious colonies isolated and identified, in the usual manner. The results are summarized in Table 1.

TABLE 1

	Cultures Made after (Hours)		
	0	6	24
<i>Without phage</i>			
Infected stool	+	+	+
Infected stool and formaldehyde			
1:20,000	+	+	..
1:10,000	+	+	..
1: 7,500	+	—	..
1: 5,000	+	—	..
<i>With phage</i>			
Infected stool	+	—	—
Infected stool and formaldehyde			
1:20,000	+	—	..
1:10,000	+	+	+
1: 7,500	+	+	+
1: 5,000	+	+	—

Both Flexner and Shiga organisms survive in phage-free stools for 24 hours. Formalin in a concentration of 1:7,500 kills the organism in 6 hours. Lower concentrations have no effect. When phage alone was added dysentery organisms could no longer be recovered after 6 hours, but when phage and formaldehyde were added cultures were positive after 24 hours even in a formalin concentration of 1:7,500, presumably because part of the formalin was bound by phage.

A second type of experiment was made with dysentery stools. These fresh stools were diluted and bacterial counts made. To one portion, 1:10,000 formalin was added, the stools were kept 24 hours at room temperature, and again diluted and cultured. The counts of the two sets of plates showed practically the same number of organisms; in one fresh stool the number of Shiga bacteria was 173×10^4 , and when plated after 24 hours with formalin the count was 170×10^4 . The concentration of formalin used had no lethal effect on

the dysentery or other bacteria present in the stools.

The procedure was then applied to dysenteric stools sent to the laboratory for diagnosis. Only fresh stools were used in these tests. Immediately on collection they were tested for the presence of phage and divided into three parts. One part was kept as control, and to the others formalin in concentrations of 1:10,000 and 1:7,500, respectively, was added. The various samples were plated promptly on MacConkey, and again after being 6 hours and 24 hours in the laboratory.

Of the 63 fresh stools examined 47 were positive for dysentery—Flexner or Shiga. All the positive stools contained also dysentery bacteriophage. Of the untreated stools recultured after 6 and 24 hours, only 14 still yielded dysentery bacteria. Of the 63 stools treated with formaldehyde and cultured after 6 and 24 hours, 49 were positive.

Thus the formaldehyde treatment gave a higher percentage of positive stools and the stools remained positive 6 and 24 hours after they were brought to the laboratory. Because of the different consistencies of stools it was found desirable to use two formalin concentrations; when there was much blood in the stool the higher concentration gave better results.

SUMMARY

Dysentery phage is probably responsible for the rapid death of dysentery bacteria in stools brought to the laboratory for diagnostic purposes. Hence stools kept for some time before culturing give negative findings. This handicap is removed by the addition of concentrations of formalin (1:10,000 and 1:7,500) which inactivate the phage but are not lethal for the bacteria. Of 63 dysenteric stools cultured almost immediately after they were voided, 47 yielded Flexner or Shiga bacteria; cultured 6 hours later only

14 were positive. However, when the formalin was added to portions of these stools in concentrations of 1:10,000 and 1:7,500, respectively, 49 of the stools gave positive cultures after standing 6 and 24 hours respectively in the laboratory. This procedure should enhance the efficacy of laboratory diag-

nosis of dysentery, and under field conditions should increase the success in detecting acute and carrier conditions.

Completeness of Birth Registration in the United States in 1940

ROBERT F. LENHART, M.S.P.A.

*Chief, Vital Statistics Consulting Service, Division of Vital Statistics,
Bureau of the Census, Suitland, Md.*

AS many of you know, during the 1940 Census a special effort was made to test the completeness of birth registration in the United States. This test was the first conducted simultaneously for every state in the country. The plans for the test have been discussed before groups of registrars of vital statistics several times and no doubt many of you know very well the procedures that have been used in the test during the past two years. However, for the benefit of those who are not familiar with the major elements of the test, I should like to review it and indicate the results.

A test of the completeness of birth registration has many values. First, it is an indication of the efficiency of the state registration mechanism. Second, the figures resulting from such a test are of considerable value in the analysis and use of birth statistics, both for interpreting the birth rates published annually and for estimating populations. Third, a test of the completeness of birth registration indicates what proportion of the children born in a given year is missed entirely in registration of births so that there is no official record of their citizenship, age, or parentage. The importance of birth registration completeness has been pointed up considerably during the past year by the overwhelming increase in requests to state offices for certified copies of birth certificates and the flood of applications for delayed registration by

persons whose births were not registered.

The 1940 test is based on a list of children born during December, 1939, January, February, and March, 1940, who were enumerated on "infant cards" by census enumerators. These cards contained certain information not available on the regular population schedules, such as exact date of birth, exact place of birth, maiden name of mother, and hospital of birth. To match against this list of children, special copies of birth certificates were obtained from each state bureau of vital statistics for all children born during the same four months. In addition, a special copy of the death certificate was secured for each child born during the four months of the test period who died during these same four months. The object of the test was to match the birth records with the infant cards and the death transcripts to determine what proportion of the children enumerated in the Census was actually registered.

All these records were sent to Washington, where, with the help of a WPA project, the preliminary processing of the records was carried out. The first step was to arrange the infant cards, birth transcripts, and death transcripts by state of birth. This meant, for the infant cards and the death transcripts, a reallocation from the state of residence at the time of the Census, and from the state of death, to the state of birth. When this was accomplished, all three sets of records had been

placed on a comparable basis by state of birth.

The second step was to alphabetize all three sets of records by surname of child. This was by far the most time-consuming portion of the test and took many months to complete effectively.

The third step involved matching infant cards and death transcripts with birth transcripts. This part of the procedure was carried out very carefully. Objective standards for matching were established before this phase of the work was begun. When the matching for a state was completed, every set of matched records was verified by a specially trained clerk to see that the standards had been maintained. By this means, we believe that the results of the test have been kept strictly comparable for every state. When the matching was completed, about 75 per cent of the records eventually matched for each state had been placed together.

The fourth step comprised the writing of 162,000 form letters, chiefly to parents, in an effort to clarify or complete the data on the remaining unmatched infant cards. The letter requested the parents to send to the Bureau of the Census certain data on their child, such as the name of the child, place and date of birth, maiden name of mother, name of father, and the name and address of attendant at birth. The replies represented an unusually high percentage of letters returned compared to the number mailed. By writing follow-up letters and letters to hospitals when no answer was received from the parents, it was possible to obtain data for about 80 per cent of the children whose birth certificates could not be located. The information given in the letters served as an accurate check on the names, places, and dates of birth of the children given on the infant cards. In many cases it was possible to go back to the files of unmatched birth transcripts with the

new information obtained from the letters and find the birth transcripts for the children in question. On the other hand, if, after receiving a letter with full information, a birth transcript could not be located, it was clear that no birth record was available for that child in the file of special copies of birth certificates.

Another type of information gathered by the letters was a statement of date of birth, which indicated whether a given child was born within the four months of the test period, before the test period, or after it. With a verification of this fact from the parents or hospital of birth, it was possible to eliminate from further consideration in the test all infant cards representing births occurring before or after the test period.

The fifth step in the procedure was the tabulation of the results of the work in the Bureau of the Census. The percentage results are shown in the first column of Table 1. The asterisks indicate states which have a special problem due to race. When it is possible to do so at a later date, a race breakdown will be given for these states so that more detailed analysis of the significance of the figures may be made.

The sixth step was to take the unmatched letters from parents and copies of the unmatched infant cards and death transcripts, for which no letters had been received, to state bureaus of vital statistics for a final check in the original files. There were several reasons for this. First, there are certain limitations in matching when relatively untrained clerks match a set of records covering the entire country. The trained personnel of a state office becomes extremely proficient at locating particular records. Such clerks become familiar with unusual names and their variations in a way that newly trained personnel do not. Second, when the birth transcripts for the test were forwarded to

* These states have a special registration problem due to race. Tabulations including a race breakdown will be available at a later date.

the Bureau of the Census, they were generally made only for those children born during the current month whose births were registered on time. Transcripts of certificates filed later often were not included among those sent to the Bureau of the Census. The process of transcription for the test was a special job and in many states certificates

filed late were difficult to locate. As a result, when the matching in Washington was completed, the records for a number of children were actually on file in state offices but were not available for searching in Washington.

The Bureau of the Census was able to send a field agent to almost every state to assist the state registrar in

making a thorough check against his state files. In all states where indexes to the filed records were available, a search was made first through the index, then, if it seemed desirable, a further check was made through the individual certificates to locate any additional records which might not be indexed. Also attempts were made in each state to check adoption files, records from foundling homes and other similar institutions, to determine whether a child for whom an infant card or death transcript had been made was actually registered under another name due to adoption or some other reason. In those states where indexes were not available, it was necessary to do all searching through the original records after sorting the infant cards and the death certificates into an order similar to the filed birth certificates. The matched records were returned to the Bureau of the Census. The unmatched records were left in the state for a further check in the field.

After the matched records were returned to Washington, a further tabulation was made, showing the results of the state office checks. The percentage results are shown in the second column of Table 1. It may be seen that the percentages of completeness of registration for all states are somewhat higher as a result of the state office checks. These are not the final figures of the test. Further modifications were effected by the field checks conducted by each state bureau of vital statistics.

At the time of the check in state bureaus of vital statistics, it was necessary to settle the question of including in the test birth certificates filed late. It was essential to choose a date after which no birth records could be accepted for the test, for it is perfectly obvious that delayed records of birth will continue to be filed for an indefinite period after birth. It was therefore decided that birth certificates filed

after July 31, 1940, would not be included in the test. This date was chosen as a reasonable one, first, because it was assumed that four months after the close of the test period would provide adequate time to secure late birth registrations for the test. Second, as the work on the test progressed and letters were written to parents, it became apparent that these letters were a strong stimulus in effecting greater completeness of birth registration. After receiving letters in which some doubt was expressed as to whether their children's births had been registered, many parents investigated and caused the certificates to be placed on file. If a deadline for receipt of transcripts of delayed birth certificates had not been set at a date prior to the time the letters were sent out, a considerable bias in the test would have resulted.

We requested that the date of filing be shown on each birth transcript forwarded to the Bureau of the Census after the state check. All those birth transcripts filed after July 31, 1940, were not counted in the test as registered births.

The seventh step in the test was the final verification and checking on each child for whom an infant card or death transcript was available but for whom no birth transcript could be located. It was proposed that local health authorities in each state attempt to locate these children to determine, first, whether the child exists, and second, why his birth was not registered. Every state conducted such a program. It raised the percentages of completeness of birth registration from 1 to 3 per cent. In cases where a letter was received from the parents giving the requested information, it was not necessary for purposes of the test actually to locate the child or do further work in the field. It is desirable, however, that the births of these children be registered as soon as possible.

An eighth step was carried out when the unmatched records, which were checked in the field by state bureaus of vital statistics, were returned to Washington. This step was a final nation-wide matching of the remaining unmatched infant cards and death transcripts against the remaining birth transcripts. This check was followed in order to eliminate, as far as possible, major errors in place of birth given on the infant cards and death transcripts. With this step completed, the essential "checking" features of the test were finished and the final tabulations were made. The final percentages are given in the third column of Table 1.

There are probably several questions in your minds about the test which I have not yet discussed: First, by what formula were the percentages of completeness computed? Second, what will happen to states whose completeness of birth registration is less than 90 per cent?

The current formula used for computing the completeness of birth registration is the same as that used by the Bureau of the Census in past tests. It is assumed that the infant cards and death transcripts, against which the birth transcripts are checked, are a representative sample of the children under 4 months of age at the time of the test. The proportion of the infant cards and death transcripts for which birth transcripts can be located, therefore, is assumed to be the true percentage of the completeness of birth registration. In other words, the formula is "the total number of birth transcripts matched with infant cards and death transcripts divided by the total number of infant cards and death transcripts received for the test." This formula is exactly the same as that traditionally used by the Bureau of the Census. It seems to be the most satisfactory method of computing the completeness of birth registration.

According to original standards, a state had to demonstrate that its registration of births was 90 per cent complete before it was eligible for admission to the birth registration area set up by the Bureau of the Census. The policy of the Census Bureau stated in 1936 still stands. At that time William Lane Austin, Director of the Census, said: "The Bureau must continue to make tests to check the completeness of registration, but the object of such checks hereafter will be to help the state with its problems of registration rather than to threaten its removal from the registration area."

State health officers and state registrars are to be congratulated on their active and effective coöperation in making possible this test of birth registration at a time when many normal activities have had to be curtailed or even dropped temporarily because of the national emergency. The special job of transcribing birth and death records for this test was an added burden. The checking in state offices was often done under great difficulty, many times with night shifts and Sunday and holiday work. It was only by sacrifice on the part of the personnel of state health offices that the fine results of this test were possible. To them goes a major share of the credit for this first nation-wide test of the completeness of birth registration.

Final results of the test reveal that in 1940 birth registration for the entire country was 92.5 per cent complete. This means, however, that even after 25 years of birth registration, in 1940 almost 200,000 babies in the United States were not registered! This is indeed a severe indictment of the entire registration system. It is particularly serious at present when millions of adults are searching frantically for every shred of evidence to prove beyond question their age, parentage, and citizenship. Special provisions are being

made to place on file delayed birth records for these people, born before the present widespread and systematic registration of births was established.

The children of 1940 who 20 years from today cannot produce satisfactory birth records will lose even more than their parents. Each step we take toward the goal of social and economic security

for everyone makes more precious each individual's proof of his rights to such benefits. It is the responsibility of the state registrars, the state health departments, and the Bureau of the Census as well, to see that 100 per cent of our children are registered at birth. We must assure today's children their birthrights tomorrow!

Organizing a Large Community for Health Education*

G. LYNDE GATELY, M.D., M.P.H.

Health Commissioner, Boston, Mass.

ORGANIZING a community for health education is part of the democratic process. The people of America rule themselves. They are individuals desirous and capable of standing on their own feet. The health department should help the community to understand its health problems and aid in their solution.

Health education provides a way in which every individual in the community may be enlisted to carry on a part of the health program. By providing an opportunity for them to express opinions, to find and solve problems, by allowing people to help themselves, the health education program is observing our most cherished fundamentals of democracy.

This concept of health education does not agree that a publicity campaign is an adequate program. Publicity, planned and executed by professional workers, is limited in its effect because it is passively received. It is learning and not teaching which is important in education. Without participation, there can be and will be little if any learning. Fanfare may be ignored or quickly forgotten, but hours spent in discussing the problem, in planning, in executing plans cannot help but leave some impression upon the mind of the individual.

There are, of course, many problems associated with organizing the people of any city, large or small, in a health education program based on these principles. I shall discuss what we are doing in Boston as an example of health education.

The first problem which confronted us was the question of unit areas. Should the program be built for the entire city as a unit or should it be organized in separate districts? For many reasons we favored a district or sectional organization bound together by unified administrative policy. No city of a million people has a single set of characteristics. It is, rather, a group of small communities, separate in racial origins, tastes, economic status, and even languages. The greatest number of social groups which will participate actively in the programs are limited in their membership to small sections. Even nation-wide fraternal and labor organizations have their membership separated into posts or locals. Problems, too, differ widely. Tuberculosis may be widespread in one section and all but absent in another. Time and effort would be wasted in urging the people of a section to solve a problem that was nonexistent in that section.

As community organization was to be the responsibility of health educators, it was thought best to limit the activities of each worker to a sufficiently restricted area to enable her to become thoroughly acquainted. The worker should be a person known in the dis-

* Presented at the Joint Session of the American School Health Association and the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

strict, both to the residents and to the other professional workers in the schools, libraries, and social agencies. She should have the opportunity for careful study of the characteristics and the idiosyncracies of her section and for becoming familiar with the facilities afforded by the district which may be valuable in the conduct of her program.

One section of the city was first selected for organization according to this plan in order to work out the basic policy which must guide the entire health education program. In this district a preliminary study was made. Vital statistics were analyzed in order to ascertain what the more pressing health problems were. Lists of professional workers, social clubs, schools, settlement houses, physicians, and dentists were compiled. The peculiarities of the district were analyzed. After the educator had thoroughly familiarized herself with these data, it was possible to begin actual organization of the district.

In Boston, the Health Department is decentralized, each of eight sections having a Health Unit. The educator was given an office in the Unit in her district so that it would be easy for the people working with her to come together for meetings and consultations. The Unit is well equipped for such meetings, having a large auditorium and several smaller rooms for conference work.

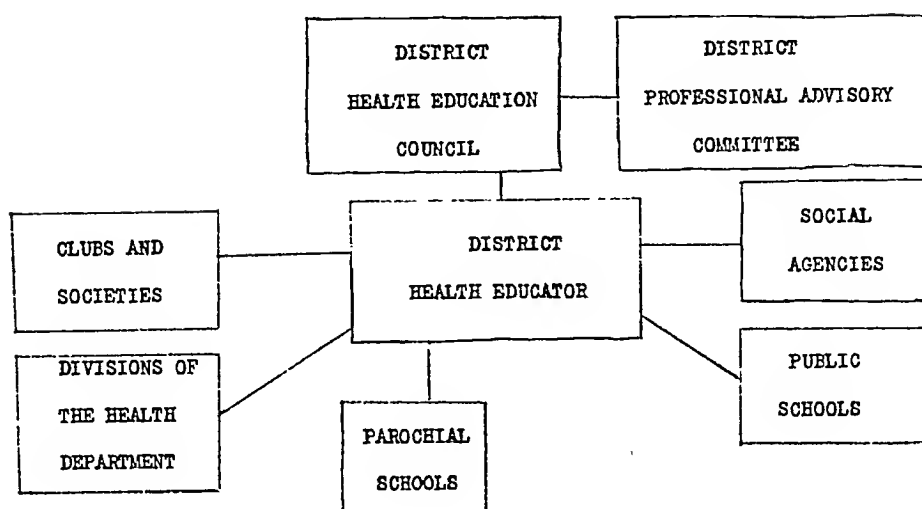

Since much health education and service begins with the private physician and dentist, the educator invited them to a meeting where the aims and policies governing the program were explained. The 30 physicians and 12 dentists were invited by personal visit. A separate meeting was held for each group. At these meetings, they were asked to select a committee of three to represent them in conference with the other groups. In much the same way, other professional workers were ap-

proached and the aims of the program were explained. These groups included the churches of all denominations, both the public and the parochial schools, the settlement houses, the Community Health Organization, visiting nurse agency, and the library.

Up to this point the program had concerned itself only with professional workers. The educator had, however, in her conversations with these workers, learned the names of many individuals living in the district who might be termed "key people." One of these accepted the chairmanship of the district committee or council. Through several conferences between the chairman, the district health educator, and the administrative consultant for the program, Professor Clair E. Turner, other residents of the community were selected to be members of the committee. In order that these lay people who were taking part in the program would not feel overwhelmed by the weight of the professional group, it was thought best to have two committees, one professional and one lay. The two were bound together by the health educator who served as secretary of each and by the chairman of the lay committee who also served as chairman of the professional committee.

The lay committee met each week. The first meeting permitted them to get acquainted with each other and with the aims of the program. They liked the idea of having an opportunity to improve their district. The section has a relatively low economic status and many of the people are employed in the large market area adjacent to it. Parts of the section enclose week-end street markets.

The committee members were frank in their evaluation of their section, and were not reluctant to acknowledge the presence of many health needs. Since it was agreed that only one major problem should be considered at a time,

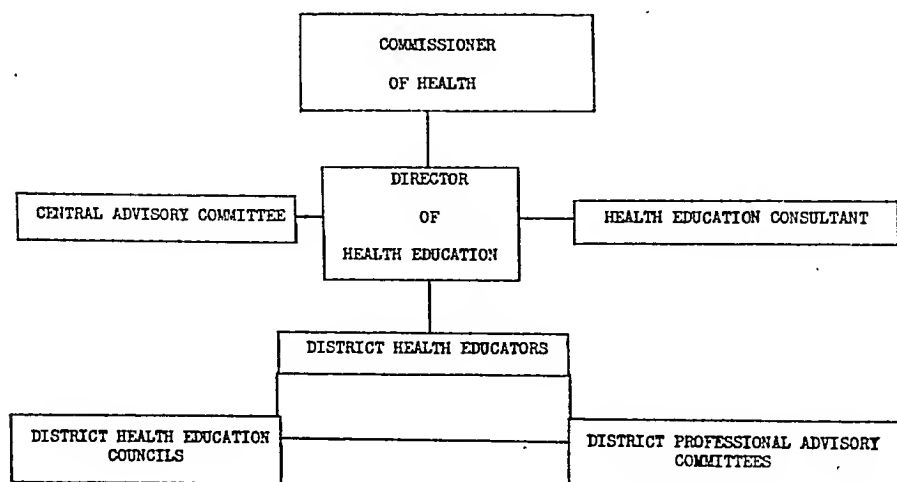

ORGANIZATION OF A DISTRICT FOR HEALTH EDUCATION

they were anxious to select the most pressing need.

The survey method was adopted. Using materials provided by the educator, each member analyzed a given area. These reports were discussed at an open meeting and the problem was selected. The health educator is able to guide the committee to some extent

in its selection since she has the information which enables her to explain needs and problems to her group.

The first problem this group elected to solve was that of rat control. Time does not permit a long description of the activities carried out by the committee concerning this problem. In the course of the months during which this

ORGANIZATION OF THE CITY FOR HEALTH EDUCATION

question was their main concern, they held an open house at the Health Unit, explaining rat control by means of exhibits, movies, and speakers. They helped the educator work out a leaflet and a poster which were printed and distributed. Exhibits were placed in store windows, libraries, and settlement houses. The health educator provided a teaching unit for each teacher in the sixth, seventh, eighth, and ninth grades. Many excellent pieces of pupil work attest to the efficacy of this phase of the program. The children also attended illustrated lectures and movies which the educator provided at school assemblies.

Other divisions of the Health Department coöperated with the program. The nurses distributed fliers announcing public meetings to the people with whom they came into contact. The sanitary inspectors gave advice on rat control. The food inspectors urged all food handlers to take proper steps to rat proof storerooms containing supplies.

After the program was under way, the need was felt to reach every person in the district. The committee members were willing to visit every home but considered themselves inadequate to render expert advice on this subject, even though they had familiarized themselves with all the available literature. The sanitary division of the Health Department was asked to help, and two rat control experts were placed at the service of the committee. It was decided to make a sample survey of a typical block in the district, tabulating the findings of rat infestation and giving rat control advice to every landlord and tenant. Each house and every apartment was to be visited. Survey forms were prepared under the guidance of the consultant in sanitation, Professor Murray P. Horwood. The Division of Predator Control of the U. S. Department of the Interior helped both in the preparation of the survey cards

and in the sample survey. A definite procedure was agreed upon for the uniform recording of findings.

The results of the sample block survey were so convincing that it was decided to survey the entire district. This work is still continuing. The people of the district were anxious to have the survey extended to all parts of the section and urged the committee to have the Health Department inspectors reach their homes. The committee members advised the people of a block that the inspectors would visit them the next week. In this way the inspectors, coming by invitation, are then expected and find all the people very coöperative. The resident accompanies the inspector on his survey so that he may learn what evidences there are of rat infestation and ways of overcoming the rodent. Literature is left with each person. In this way, the survey has become a people's project and involves true education rather than merely survey statistics.

This description of some of the activities of the committee, illustrates the way in which all the facilities of the district are concentrated on a single problem. Unlike short campaigns, this type of program has the advantage of continuity. Children and adults alike are frequently reminded of their part in solving a community problem. There has not been one instance in which co-operation was refused. Some people are more active than others, but that is to be expected.

The problem is by no means solved as yet. Rat control is too big a problem with too many ramifications beyond the control of the individual to be entirely solved in a few months. The program has, however, awakened the people to the recognition of the existence of the problem. They now know the dangers of a large rat population. They know what rats cost the community. They are now beginning to do something about rat control and they have

the information they need to work intelligently.

There is another important feature of our district education organization. It became apparent that unless a large number of the residents felt themselves a part of the program, the committee would resolve itself into just another group in a district thickly studded with social organizations of various kinds. To avoid this possibility, it was decided to form the North End Health League, with individual members who were residents of the district, and group members consisting of clubs, societies, and labor organizations. The lay committee was to be the executive group, calling itself the North End Health Council. Each club joining the League was to have the privilege of sending a representative to the council. The members of the original committee undertook this task of securing group members. The list of social groups was carefully checked and clubs purely political in set-up were eliminated. About twenty-five organizations were invited to join, most of which did so immediately. In this way, such groups as the American Legion posts, the Veterans of Foreign Wars, and many others became members of the council. Their club meetings now became ready-made audiences for the program. There is no need to try to gather an audience, since the total membership of these clubs includes practically every adult in the entire district.

I have described the organization of a single district in fairly complete detail, since it illustrates the principles employed by the health education program. We have a city-wide advisory committee of experts from other organizations, which discusses all plans with the consultant and the health educators. In this way, we have the benefit of their advice and avoid conflict with other programs. Very often valuable assistance is obtained. One of the

representatives of the advisory committee, for example, is the head of our Community Health Association which provides the visiting nurses in our city. These nurses are very coöperative and help wherever possible. Their support of the program, permits a multiplicity of approaches that makes for good education. This type of coöperation also permits an impartial evaluation of the work accomplished and does away with many pitfalls that otherwise might not be avoided.

As a health officer, I am particularly enthusiastic about the benefits of a health education program. Since the educators work in close contact with the residents of the community, they can help in interpreting the work of the other divisions of the Health Department. They form a contact between the people and the technical workers of the department. By interpreting the purposes and services of the Health Department, they make the residents of the city far more receptive to its work.

Since February 1, 1943, the services of five health educators as well as the continued consultant service of Dr. Turner have been available to extend this program on a city-wide scale. The Health Department has always had the complete responsibility for health work throughout the parochial school system. A new curriculum in health education has been completed by the Director of our Health Education Service, working with committees from the Health Department and the office of the Diocesan Director, for use in these schools. The district health educators are also acceptable to the public school system, since they hold the degree of Master in Education as well as the Certificate in Public Health in the field of health education. This makes possible the simultaneous development of school health education and adult education as illustrated by the

rat control program in the North End.

There are, of course, certain city-wide activities of public health education such as printed matter, newspaper articles, radio exhibits, and in-service training of personnel. These are an important part of health education, but I believe a health education program which consists only of these activities is far from adequate. The essence of good health education in a large community, as I see it, is the organization of key people and social groups in the

various sections of the city to find and to help solve their health problems. With such a program, the health department can really become the appreciated servant of the people instead of a policing agency. This recognition and appreciation of the value of a strong and well equipped health department is reflected by active support for new programs and adequate working funds. A health education division, staffed by well trained workers, is an essential part of any public health department.

Development and Management of a Cotton Rat Colony*

D. B. MEYER, D.V.M., M.S., AND MARTHA MARSH, M.S.

Bureau of Laboratories, Michigan Department of Health, Lansing, Mich.

FOLLOWING the announcement made by Armstrong¹ that poliomyelitis virus could be transmitted to cotton rats, the Michigan Department of Health Bureau of Laboratories obtained wild stocks² of *Sigmondon hispidus hispidus* (Figure 1) from Florida and South Carolina, and of *Sigmondon hispidus littoralis* from Florida and Georgia, and has attempted to raise them in captivity.†

Approximately 500 trapped wild rats were the foundation of the colony which was started November, 1939. Subsequent to September, 1940, 7,800 young have been produced from this colony which has averaged about 180 pairs of breeders. At the present time the colony is composed of 250 pairs of breeders which produce about 700 young per month.

EQUIPMENT

A cotton rat colony can be housed in any quarters suitable for the raising of small animals. However, it has been found necessary to design and build a special cage 20" x 10" x 10" for breeding purposes (Figure 2). The cage, constructed of sheet iron and screen, and coated with aluminum paint, has

an enclosed nesting compartment with a removable "Masonite" bottom. The exercising and feeding compartment has screen sides and removable screen bottom. A tray containing wood shavings slides under both compartments. The breeding cages are grouped in units of 25 on movable iron racks.

Young animals following weaning, and animals ready for test, are kept in small animal cages (Figure 3) which are mounted on rubber tired trucks in batteries of four.

WORK SCHEDULE

In maintaining the cotton rat colony the following duties are carried out routinely:

1. Daily: Water and inspect all members of the colony, recording births and deaths.
2. Three times a week: Feed all members of the colony.
3. Weekly: Wean all 3 week old rats, discard nonbreeders, pair new stock, and clean all cages.
4. Monthly. Wash and sterilize all cages and drinking bottles.

FEED

From the great variety of foods which have been offered to the cotton rats, the following diet has been adopted because the rats have eaten it readily, have apparently thrived, and have reproduced satisfactorily.

1. A mixture of 1 part sunflower seed and 3 parts of rolled or whole oats.
2. Equal parts of commercially prepared fox and mouse pellets.

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

† Aided by grant from the National Foundation for Infantile Paralysis, Incorporated, and the Works Project Administration.

3. Fresh apples, carrots, tomatoes or alfalfa cuttings.

4. Water (from glass bottles equipped with hanging drop dispenser).

MANAGEMENT OF BREEDERS

Six week old cotton rats of healthy and sturdy stock are selected for breeders, and are permanently marked by a system of ear and toe markings. At the time of pairing, a breeding record is compiled for each male and female. This record includes information regarding sex, generation from wild stock, identification number, date of birth, and production record.

Under the present system of management, matings of a male and a female are permanent except in certain instances when it is found possible to rotate one male among several females.

Male and female rats from 6 to 7 weeks of age are sexually mature and are ready to be paired. In studying vaginal smears from a limited number of females, it has been found that the estrous cycle is irregular, varying from 4 to 8 days, with an average of 5.7 days. The period of gestation varies from 26 to 28 days. The average number per litter is 5, with 11 the maximum that has been encountered. Newly born animals have averaged 7 grams in weight and are well haired out at birth. They have begun to run around the cage at an early age, have eaten solid food within about 1 week, and have been ready to be weaned at 3 weeks of age.

The average production span of a female cotton rat is not known. The

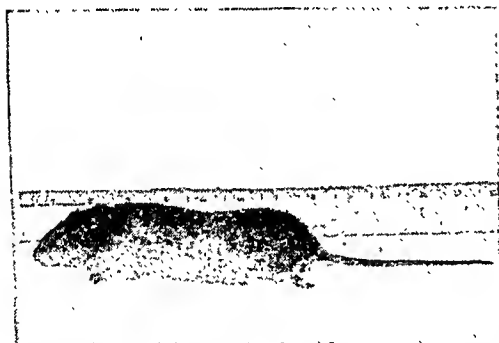

FIGURE 1—Female cotton rat, 1 year old

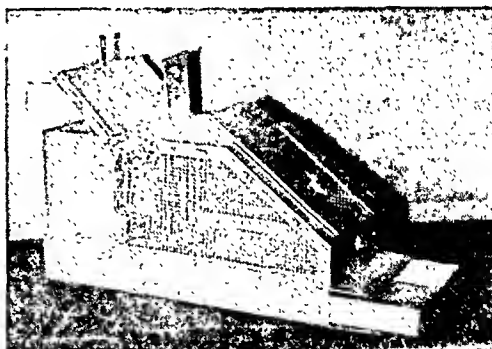

FIGURE 2—Cage used for breeding

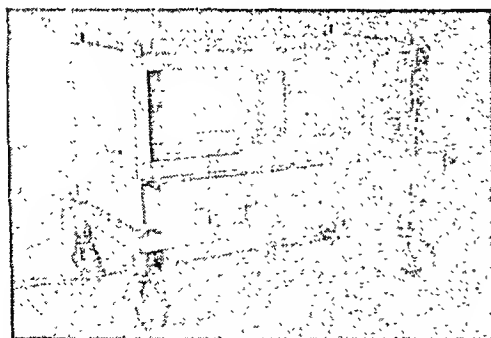

FIGURE 3—Cage used for weaned stock and animals ready for test

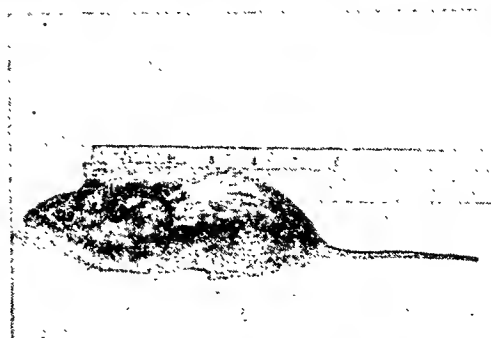

FIGURE 4—Male cotton rat, 6 months old, affected with alopecia

oldest rat in the colony that is still producing is 20 months old. This is a 2nd generation female which has a record of 70 births in 13 litters.

Precautions must be taken in the handling of cotton rats and it is advisable not to disturb the newly born rats. The 8th generation rats, born in the colony, are as nervous and likely to bite as are rats when first trapped. Heavy cowhide gloves must be worn when handling rats 2 weeks or more of age. The animal should be grasped firmly at the nape of the neck, as handling the rat by its tail usually results in stripping off the skin.

Through a system of close inbreeding, it may be possible to produce a specific type of cotton rat which would be more uniformly susceptible to viruses. From a group of 10 brother and sister matings, three pairs were selected to be used as the basis of three pure strains of animals. One strain which showed evidence of lighter hair coloration has produced 4th generation rats of sturdy stock.

LOSSES AMONG COTTON RATS

Losses among cotton rats have been mainly due to three factors: mechanical injuries which have resulted from fighting among mature animals or from improper handling by attendants; sacrifice of rats in an effort to eliminate and control alopecia; and a small percentage loss from possible bacterial infection, internal parasitism, or starvation.

1. Among total deaths in breeding stock 45 per cent have been due to fighting. The loss has been roughly 60 per cent among males and 40 per cent among females subsequent to their pairing or parturition. This loss of breeding stock has been materially reduced by washing each member of the pair with a 1 per cent pine oil or coal tar disinfectant solution in order to destroy their natural odor. A small unknown percentage of animals die as a result

of injury during handling or have had to be killed because of severe injury inflicted by cage mates.

2. A number of rats have been sacrificed in an effort to eliminate and control alopecia, or loss of hair, which has occurred in rats of both species and of all ages. Subsequent to its discovery over 400 rats have been affected to varying degrees by this condition. Alopecia is usually first noticed in the dorsal-lumbar region where the loss of brown-tipped guard hairs results in exposure of the dark underfur. In advanced stages the back becomes almost denuded of hair (Figure 4) and the area eventually extends forward to the head region. The condition has also been exhibited in other specific regions such as around the eyes, on the forehead, and at the base of the tail.

The cause of alopecia is uncertain. Ringworm spores have been found in the shafts of hair taken from affected areas, but they may not be the primary cause of the condition. No animal has ever lost weight or died as a result of the condition.

3. Losses due to bacterial infections, internal parasitism, or starvation have been small. Bacteriological examinations made on rats that died of unknown causes have revealed the presence of a variety of bacteria including green producing streptococci, staphylococci, and organisms of the *Proteus* group. Cotton rats evidently are not very susceptible to organisms of the *Salmonella* group since the colony, for the past year, has been housed with a colony of mice where *Salmonella* infections have been present. Furthermore, cotton rats experimentally have resisted artificial oral exposure to *Salmonella* organisms.

Internal parasites have been recovered from trapped wild animals which died during or soon after shipment. Of 170 wild animals thus examined 49 were found to be infested with either tapeworms, roundworms, echinococci, or

microfilaria. Fleas and lice also were found on the wild stock. No parasites of any type have been found in any of the animals that have been raised in the colony.

Cotton rats apparently are not very hardy and easily die as a result of moderate starvation. In cages where large numbers of rats are kept the food supply occasionally becomes low over week-ends, the rats become weak, refuse to eat, and some of them die.

A loss of 9 per cent has been observed among young animals prior to weaning. The exact cause of this fatality is unknown. Deaths following premature births have been recorded

and some adults have killed their young soon after birth.

SUMMARY

The development and maintenance of a cotton rat colony for use in poliomyelitis research by the Michigan Department of Health, Bureau of Laboratories, has been presented. By careful management, cotton rats can be successfully raised in captivity.

The Opportunity for the Engineer in the Field of Housing*

ABEL WOLMAN, DR. ENG., F.A.P.H.A., AND
ALFRED H. FLETCHER, F.A.P.H.A.

Professor of Sanitary Engineering, and Associate in Sanitary Engineering, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

SIXTY years ago little was known as to the factors required to produce a safe and potable water supply. Today, through laboratory research and controlled field experience, the sanitary engineer has the tools to diagnose and prescribe for almost any specific water supply problem.

The objective, however, will not have been realized until safe potable water reaches the consumer in the home and the waste is returned to some point for safe disposal. The real property inventory surveys¹ made in 1934-1936 indicate that 15 per cent of all families living in cities in the southwestern part of this country do not have running water in their homes, and 32 per cent of all families in southeastern United States are without private indoor flush toilets. Enforcement officials know well that outside community toilets, even when of the type connected to a sewer, are not satisfactory because of the high percentage of stoppages and other insanitary conditions, due to improper use, freezing, use of inadequate flushing devices, and lack of responsibility for maintenance, typical of most outside community toilets.

Other figures on housing from this same study¹ emphasize the magnitude

of the slum phase of the housing problem which is of primary concern to public health officials. For example, 13.9 per cent of all dwelling units in the United States needed major repairs with 2.3 per cent unfit for use. These figures vary from 20 per cent needing major repairs and 3.4 per cent unfit for use in the southeastern section, to 12.8 per cent and 2.3 per cent respectively in the northeastern section.

Of the families living in urban communities, 8 per cent paid less than \$9.99 a month for their living unit. The average percentage figure varied from 5.9 in the northeastern section to 36.6 in the southeastern section. In other words, more than one-third of the families of the southeastern section of the United States did not pay enough rent during this period to finance anything more than a shack without a toilet or sink and without other protection from the weather and insects.

According to Shelby M. Harrison² the 1942 President of the National Conference of Social Work, one-quarter of the population of the United States in 1933 needed public assistance and one-ninth even in 1940 needed it.

INADEQUACY OF PIECE-MEAL APPROACH

The problem of providing safe and healthful housing for all families may appear at first glance to be one primarily of forcing property owners to

* Presented before a Joint Session of the Conference of State Sanitary Engineers and the Conference of Municipal Public Health Engineers in St. Louis, Mo., October 26, 1942.

maintain or improve their property to meet a minimum standard. Tenants, however, have something to do with whether a house is substandard or not. The income from the property is influenced by the neighborhood environment and the state of repair in turn by the income of the tenant. The level of rents varies with the cycles of prosperity and depression and with the shifting of population and consequent change in percentage of vacancies. The difficulty is further complicated by an unbalanced allotment of areas in zoning plans, for business, industrial and residential use, and by heavy street traffic, lack of playground space, lack of nearby schools, churches, and shopping centers, heavy railroad traffic, heavy smoke, or inadequate transportation facilities.

It is not simply a matter, therefore, of the official accepting an assignment from the local newspaper, or a demand of public opinion, or even a request from the city administration to clean up the slums, but rather one of defining and measuring the problem on the basis of facts secured through objective investigation. The executive health officer and the engineer can then develop a housing philosophy and a plan of action commensurate with the importance of good housing as one of the foundation stones in a public health program, and co-ordinated with the plans of other local departments and agencies concerned with the housing problem.

The major effort at this time, however, in both man-hours and manpower, in some, if not most, of the divisions of sanitation in municipal health departments throughout the United States is directed toward the correction of insanitary conditions about the home. Even the directing health officers evaluate most of these programs as of minor public health significance and place them in the nuisance category. At the end of any year's work many of the grossly insanitary

conditions complained of are still uncorrected and at the end of each 10 year period about the same proportion of slums remains.

The Committee on the Hygiene of Housing is urging that the housing problem be met as a coördinated community program, and not as the usual routine enforcement program within the complaint division of many departments without reference to any overall objective and plan.

Dr. Huntington Williams, Health Officer of Baltimore, expressed the same feeling when he commented on his own experience.

It was apparent that the team in question was very much like a group of football players who were placed on a field without uniform, without preliminary coaching or training and under the gaze of an expectant grandstand, were called upon to produce with promptness a series of touchdowns; further, it became promptly apparent that no rules or signals had been established for their teamwork. From the early efforts it appeared as though one or another of the team at the signal secured the ball but ran in the wrong direction and made a touchdown for the opposite side.

A COMMUNITY PROGRAM

Some of the specific projects or programs in any community, which considered jointly make up a well balanced program, may be listed as: low cost subsidized housing projects, a planned long-range health department enforcement program, a sound real property tax delinquent policy, a sound rental policy of the welfare agencies, up-to-date legislation for the control of new housing, an enlightened nursing program, technological programs to reduce the cost of present assembly practices in building houses, an up-to-date balanced zoning plan, private housing construction and maintenance, and a definite plan for the rehabilitation of blighted areas. A coördinated program of this kind requires, of course, a leader

in each community, who must take the initiative in developing such a program and in obtaining the necessary team work for its accomplishment.

Some useful tools³ for measuring and defining the housing situation in any community have been developed by the American Public Health Association's Committee on the Hygiene of Housing.

Minimum standards⁴ for healthful housing have also been developed as a guide for the design and construction of all new housing. Practical standards which enforcement agencies can require as a condition to permitting occupancy in existing housing units, may have to be less than the ideal, and may vary for different communities according to the wage scales and the housing standards already prevailing in the community.

Once these practical standards are established, the annual cost required for remodeling and maintaining existing housing to meet the standard may be estimated. Incomes and rental paying ability of the population, when known, determine the percentage of families not able to pay these rentals. The sections of the city in which these people live will coincide roughly under usual conditions with the slum boundaries or the areas where houses needing major repairs predominate.

Besides the opportunities for leadership in the administrative aspects of the housing program, because of his position as engineer in the local health department, the planning field offers additional ground for action. City and regional planners have given little time and thought until recently to housing as one of the most important factors in the development of a sound plan for any community.

In large cities often as high as one-third of the areas subdivided for residential buildings have never been used, while large high taxed areas in the center of cities are being abandoned by

higher income people to slums and blight. Those who can afford it move to suburban areas which are often unplanned and without satisfactory arrangements for water or sewerage. The problem of supplying public utilities to these new areas and the impending waste of scrapping much of the large piping systems already installed in the old areas needs study and planning for more efficient land use.

The present necessities in supplying war housing must be blended with future objectives. Planning for post-war construction projects to tide us over while both the armed forces and defense industries are being demobilized should be particularly attractive to sanitary engineers, since housing is expected to play an important rôle in that period.

BUILDING AND FINANCING HOUSES

The cost of land, materials, and labor reach a minimum figure of about \$4,500 for a 4 room house with a 60 year life, even when built on a mass scale by the government. Under the normal system of building houses to sell, 80 per cent of all⁵ the new housing built during the boom years of the 1920's was built for sale or rental to the top 18 per cent of the people in the maximum income group.

Data prepared by the Division of Economic Research⁶ of the Bureau of Foreign and Domestic Commerce indicate the influence that the method of financing has on the percentage of people who can afford new housing or the lowest level of income that would support a new home. If a payment of \$20 a month at 8 per cent interest, amortized over a period of 20 years, will finance a \$2,500 house, the same payment of \$20 a month, at 3½ per cent interest and amortized over a period of 40 years, would finance a house that cost over twice that figure, or \$5,200.

The federal government's interest in encouraging private housing construction through the Federal Housing Agency has resulted in longer-term amortization periods, lower interest rates, and inspection to insure sound construction. This has resulted since 1935 in an increase in the production of new houses for families in income classifications previously considered as unsuitable markets for new houses. In 1936, for example, the median FHA valuation of new single family homes on which mortgages were accepted for FHA insurance was \$5,625, including land, while in 1940 this figure had declined to \$5,059. Since 1940 there has been a persistent downward trend in both valuation in homes built, and in the percentages of families having incomes less than \$2,500 and of \$2,000 who had invested in new homes.

Building laws, in some cases too stringent and outmoded, have added to the cost of building, and have limited the income group for which housing was built.

The building industry⁷ has been developed from a number of handicraft trades erecting the luxury type of house. It must be completely reconstructed to provide more efficient and less expensive methods of fabrication before any great saving in house construction can be realized. Cheaper and better materials are also needed. That the construction industry⁸ is awake to this challenge is evidenced by their efforts to encourage courses and training for engineers for recruiting by the industry. Courses are now offered in light construction engineering at 11 recognized engineering schools.

In normal years, 50 per cent of the total construction volume in dollar value is in housing construction. The U. S. Department of Commerce⁹ has recently estimated that the dammed-up demand for housing will reach 40 billions of dollars by 1945.

HOUSING, A PROBLEM FOR LOCAL ATTENTION

Although the problem of housing may be viewed on a national level, it is fundamentally a problem arising from local conditions. The local building, planning, enforcement, zoning, and taxing programs, as they affect housing, must be rationalized on the basis of the actualities in each specific community. Leadership is required to stimulate coordinated action by all those agencies whose individual programs provide the answers to some of the housing questions.

Continuing authoritative information, if available, would be of inestimable value to planners, enforcement officials, mortgage agencies, real estate interests, and even the renters and purchasers of housing who would benefit by a more stable and predictable housing market.

The future holds promise of an expanding program of public health activity in the fields of nutrition, housing, and medical care for all the people. Of these, no one field holds more challenge for the public engineer than that of housing.

No profession or group today, whether architect, builder, lawyer, doctor, or social worker, has the background of education, training, and experience to fit them better to lead in the sound development of a housing philosophy and program than the engineer in the local health departments. Why do they not meet this challenge as they have met other difficult issues in environmental control of the past three decades?

“Doctor Jones” Says—

A letter I saw the other day: there was an article in *Health News* a while back about public health nurses and the war—said what a serious matter it was when one nurse left that was covering a whole rural county and how, in the big places where several nurses were employed by different agencies, their services ought to be coördinated so they could release some to handle these rural situations. It seems this woman read that and she wrote to the Health Department: said a lot of good nurses had gone to work in war industries; she thought there was something wrong, somewhere, when a nurse could get paid more on a job she knew practically nothing about than in the vital work she was 'specially trained for. She's got something there, that woman has.

The folks that're running the war—the Government—they recognize that protecting health on the home front—it's a necessary part of the war effort. In fact it's more important than ever. With people shifting around from this place to that and men coming back from tropical countries with new diseases and so on, there's more danger of epidemics and disease being spread around—to say nothing of morale. And this job of protecting health, it can't be done by just anybody that happens to be handy. It takes people with special training and experience: doctors, nurses,

sanitary engineers and milk sanitarians. It certainly don't look like good management to waste that kind of training and experience on a job somebody else could handle just as well—maybe better.

Of course the doctors—they've got this Procurement and Assignment Service—the Army and so on won't take 'em if this Board says they're essential where they are. Anyway, if I was a soldier and was sick or wounded I'd want a doctor that'd been practicing medicine—not doing public health work. And the engineers—I understand they're organizing the same sort of system for sifting 'em out.

The milk sanitation—in the Army it's all veterinarians. I suppose that's a hang-over from the old raw-milk days when the most they thought of was the cow. A veterinarian at least knew which part the milk came from. But today it's special training and experience that makes milk sanitarians, not what college they graduated from. Just being an M.D. or a D.V.M. don't make a milk sanitarian and some of the best of 'em ain't either one.

Yes, sir. Whether it's war or peace, or men or women, it's a pretty good idea to use folks in the jobs they're qualified for.

PAUL B. BROOKS, M.D.

Health News, New York State Department of Health, Apr. 26, 1943.

Food Handlers in the Army and Their Relationship to Salmonella Food Poisoning*

WILLIAM S. STONE, LT. COLONEL, M.C., F.A.P.H.A.

Office of the Surgeon General, Preventive Medicine Service, Washington, D. C.

THE rôle of the food handler in enteric disease transmission has been extensively studied, but due to the complexity of the factors involved, coupled with inadequate knowledge and means for the detection of dangerous disease carriers, there is a tendency generally to consider them to be of less importance than other factors involved.

In general, this may be true if we consider only the family unit which in normal times constitutes the greater part of the living environment of the world's population. However, the congregation of large elements of the population in armies or cities where other than family contacts predominate in the environmental picture, such as in eating places, places of entertainment, in transportation, places of employment, and schools, presents greater opportunities for disease carriers, and particularly those engaged in food handler rôles, to transmit their infections to non-immunes. These circumstances are always more prevalent during war, disasters, or economic upheavals resulting in mass movements of populations. The present war is no exception—in fact, it is causing a more serious disruption of populations than any experienced

in the past. This is due to the ease with which great numbers of individuals can be transported to distant places with transportation means now available, and to the deep penetration of bombing aircraft into areas other than those of actual combat. This results in a greater destruction of the habitations of man and the basic industries that provide for his livelihood. Aside from the destruction of sanitary facilities and equipment, these factors all tend to break up family units and provide dispersion of disease carriers into non-immune populations, thus setting the stage for major disease outbreaks. It is therefore obvious that our civil population and our armed forces will be increasingly exposed to these detrimental influences.

The Army must by necessity gather its personnel from all sections and classes of our populations and must for training and combat purposes bring them together in large numbers. These individuals may be required to serve in any part of the world and will be exposed to whatever diseases are present in the areas concerned. Under these conditions, the food handler carriers of communicable disease will undoubtedly play an important rôle in the prevalence of disease among our troops.

There is plenty of evidence that the Salmonella group of organisms may be

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

of importance in enteric disease outbreaks that may be encountered. Experience in the Panama Canal Department during 1940 and some of the bacteriological findings in outbreaks encountered to date lend support to this statement. Small outbreaks of food poisoning, diarrhea, and dysentery had been occasionally occurring in various commands in the Panama Canal Department prior to 1940. This led in May of that year to a careful laboratory investigation of the factors involved by the Bacteriology Department of the Board of Health Laboratory, Ancon, Canal Zone, aided by a field investigation conducted by Lt. Col. W. C. Cox, M.C., Assistant Department Surgeon, Panama Canal Department. Twelve food poisoning outbreaks occurred between May and December 31, 1940, and various species of *Salmonella* were isolated as the etiological agents from the cases occurring in eleven of the outbreaks. There was a direct correlation between the species of *Salmonella* and *Shigella* isolated from food handler carriers and the cases of food poisoning occurring in each outbreak. Detection of the carriers and their removal from food handler duty stopped the occurrence of these infections in the commands concerned. It must be pointed out that the food poisoning outbreaks were usually preceded by a few scattered cases, followed by an explosive outbreak — then a continued small incidence of the disease until the food handler carriers were detected and removed from duty, after which no new cases developed.

As a part of the food handler examinations, three stool specimens were collected on alternate days from each individual and cultured for intestinal pathogens. These specimens were delivered to the Board of Health Laboratory within 24 hours of their collection and, for the detection of the *Salmonella* typhoid groups present,

were planted in Selenite F broth, followed by incubation of the broth at 37° C. for 18 to 24 hours. Heavy inoculations of the seeded broth were then made to large Endo plates (150 x 12 mm.) and bent glass rods used for streaking. It was our experience that proper separation of sufficient colonies could not be obtained by using the small Petri dishes. Further, if inhibitive media were used for plating instead of the Endo medium, that colonies picked would frequently not be in pure culture and would require further plating on Endo or E.M.B. medium before carrying out definitive studies.

After plated cultures were incubated overnight, suspicious colonies were picked and inoculated into Kligler's iron medium. Cultures on this medium giving characteristic reactions of the *Salmonella* or *Shigella* groups were tested for agglutination in 1–100 dilutions of O and H group specific sera. Those giving specific agglutination were further studied and classified by the use of sugars and morphological examination. Positive cultures roughly classified in the *Salmonella* group were then forwarded to Dr. P. R. Edwards of the Department of Animal Pathology, University of Kentucky, Lexington, Ky., for definitive species identification, as certain specific H agglutinating sera were not available locally.

Sixty-six hundred and seventeen stool specimens were examined from approximately 2,000 individuals. Of this group, 49 were found to be carriers of intestinal pathogenic bacteria, or an average incidence of 2.45 per cent. Of this group, 40 were carriers of *Salmonella* other than *Salmonella typhi*, 4 of *Salmonella typhi*, and 5 of *Shigella*.

The *Shigella* carriers were made up of 3 positive for the Sonne bacillus, and 2 for the Flexner group of dysentery bacilli. Fourteen species of *Salmonella* were isolated. The type and number of carriers of each species are given in

Table 1. The findings on all carriers were confirmed by additional cultures after the first isolation. Some of the *Salmonella* carriers yielded positive cultures over a 60 day period.

TABLE 1
Panama Canal Zone, 1940

<i>Species</i>	<i>Number of Carriers</i>

	<hr/> 44

The distribution of food handler carriers by place and type of personnel is given in Table 2.

TABLE 2
Carriers, Salmonella, Found on Stool Examination during 1940, by Place of Duty and Status

<i>Place of Duty</i>	<i>Military Personnel</i>	<i>Civilians</i>	<i>Total</i>
Albrook Field	2	1	3
Fort Amador	3	1	4
Fort Clayton	3	20	23
Post of Corozal	2	0	2
Panama	0	1	1
Camp Paraiso	3	1	4
Quarry Heights	2	1	3
Fort Randolph	0	2	2
Rio Hato	0	1	1
Fort Sherman	1	0	1
Totals	<hr/> 16	<hr/> 28	<hr/> 44

The distribution of the carriers by posts shows a total of 23 for Fort Clayton. A possible explanation of this occurrence was the size of this command and the fact that three fair-sized outbreaks of food poisoning occurred at this post during the period of investigation. The principal organism isolated from cases and carriers at Fort Clayton was *Salmonella paratyphi* B Var. Java.

The medical history of most of the food handler carriers was essentially

negative for gastrointestinal symptoms or a history of food poisoning or diarrhea within 6 months of their detection as carriers. Six of the group gave a history of diarrhea within 3 months' time, but none of them within a period of 1 month prior to the examination. One gave a history of diarrhea 2 years previously and one gave a history of right upper quadrant pain for about 1 month previous to the time of examination.

All positive food handlers were hospitalized and were not allowed to assume their vocation until repeated stool cultures over a 30 day period showed the absence of intestinal pathogens.

SUMMARY

The potential rôle of food handler carriers of *Salmonella* and *Shigella* as a possible source of epidemic disease outbreaks during the present war is

discussed and the Army experience in the Panama Canal Zone during 1940 with food handler carriers of *Salmonella* and *Shigella* presented. Two thousand food handlers were examined—44 were positive for *Salmonella*, and 5 positive for *Shigella*; 14 species of *Salmonella* and 2 species of *Shigella* were isolated. Positive food handlers were generally asymptomatic and were associated with small epidemic outbreaks of food poisoning and diarrhea.

Use of Ratings in the Evaluation of Exhibits

HOMER N. CALVER, F.A.P.H.A., MAYHEW DERRYBERRY,
PH.D., F.A.P.H.A., AND IVAN N. MENSCH

Secretary, American Museum of Health, New York, N. Y.; Chief, Field Activities in Health Education; and Junior Social Science Analyst, U. S. Public Health Service, Washington, D. C.

THE evaluation of exhibits in health education becomes increasingly essential as public health workers make more frequent use of that medium. At almost all state or county fairs, conventions, or other large gatherings there will be found one or more health exhibits, many of which are complicated and expensive. Despite increased interest in using exhibits, there is little objective evidence concerning their effectiveness. Generally the sole evaluation of an exhibit before it is put on display is the judgment of the exhibitor and his associates. Are such ratings dependable, and can large expenditures for exhibits be justified on subjective opinions?

That the validity of ratings may be open to some doubt is suggested by previous studies of ratings on the quality of drawings, English compositions, and handwriting. As early as 1910 Thorndike asked 30 judges to rate 37 specimens of handwriting for quality.¹ In rating one of the specimens, one judge stated that the writing was of the highest quality; 5 stated it was of the poorest; and the ratings by the other 24 judges were distributed throughout the range between best and poorest. Later, Thorndike,² Cohen,³ and others showed similar variations in ratings of drawings, and Hillegas⁴ demonstrated that

ratings are unreliable measures of quality in English composition.

Although as a result of such studies those in educational measurement no longer use ratings as a means of evaluating educational materials or products, constructors of health exhibits have seldom utilized any other measure of effectiveness. For that reason it has seemed advisable to investigate exhibit ratings to ascertain whether such evaluations are reliable; and the New York World's Fair presented an excellent opportunity for that investigation. Grouped in the Medicine and Public Health Building were many exhibits prepared by many health workers, with extremely diverse ideas as to effective exhibit technic, including all sorts of combinations of movement, color, and arrangement. Twenty-six major ones were selected for study.

In evaluating, two questions were posed: Could professional workers agree on the most effective exhibits in the group? Could they also agree in selecting the least effective displays?

RATINGS BY PROFESSIONAL WORKERS

Two hundred and seventy-one professionally trained persons, including public health workers, educators, students in professional school, and professional exhibitors were asked to

TABLE 1

Relative Frequency with Which 26 Health Exhibits Were Rated as "Best" or "Worst" by Professional Workers

Name of Exhibit	Percentage of Professional Workers Rating the Exhibit as One of the Three—	
	"Best"	"Worst"
Maternal Health	51.7	4.1
Maze of Superstition	26.9	10.3
Education of the Blind	25.8	1.1
Industrial Sanitation	24.7	0.7
Cancer	20.7	4.4
Dental Science	18.1	3.7
Pneumonia	17.7	8.5
Milk Control	15.5	5.7
Carrel-Lindbergh Apparatus	14.4	8.5
Heart and Circulation of Blood	12.6	8.1
Allergy	12.6	5.9
Glands of Internal Secretion	10.7	4.4
Immunity, Infections, Viruses	8.9	4.1
Syphilis—"Shadow on the Land"	6.6	5.9
Housing for Health	6.3	22.9
Tuberculosis	5.2	12.9
Chest X-ray Demonstration	4.8	17.7
Mental Hygiene	4.4	8.5
Social Hygiene in Your Town	3.7	3.3
Your Health Department	3.3	28.0
Medical Education	2.6	13.3

The Anemias, Story of Diabetes	2.2	13.3
Anesthesia	2.2	8.1
Veterinary Medicine	1.9	11.8
Child Health	0.7	16.2

review the exhibits and select the first, second, and third best as well as the three which they considered as the worst of the 26. Judgments were to be made in accordance with the following instructions:

Please rate the exhibits in the Hall of Medicine on the basis of *at least* the following characteristics: (1) clarity of presentation, (2) general attractiveness, (3) integration of panels, and (4) value of information portrayed.

In addition, the rating form provided space for the judge to state his reason(s) for rating any given exhibit as "best" or "worst."

A tabulation of the frequency with which each exhibit was rated as one of the three best or one of the three worst is shown in Table 1.

Low percentages appearing in both columns for a given exhibit indicate marked lack of agreement among the judges on its relative merit. On only one exhibit (*Maternal Health*) did as many as half the judges agree that it

was among the three best exhibits shown, and even on that one 11 of the 271 raters (or 4.1 per cent) considered it as one of the three worst.

No other exhibit was placed in the best or worst position by a majority of the raters; only 6 others were rated in a similar fashion by as many as one-fifth of the raters. For example, 73 judges rated the *Maze of Superstition* exhibit as one of the three best, but 28 others called it one of the three worst. Clearly, these data indicate that the criteria which the raters used were not applied consistently by the 271 individuals.

Further evidence of the lack of agreement between the judges is afforded through the following quotations from the rating blanks on given exhibits.

It may be argued that much of the disagreement may have been due to the different types of professional groups asked to rate the exhibits. To test that hypothesis, the judges were divided into four more or less homogeneous group-

QUOTATIONS FROM RATING BLANKS

Anesthesia Exhibit

"This exhibit portrays the place of anesthesia in modern surgery in such a manner that fear of possible pain and fear of anesthetic accident is removed. The scene of operation is quite accurately portrayed, with no attempt to dramatize the situation. The life-size moving figures are convincing. One leaves the exhibit with a feeling of reassurance."

"Here is an opportunity for a fine piece of work and what is there here—nothing but a hospital operating room—offers nothing to onlooker in an educational way. One glance and people walked away."

Dental Exhibit

"Presented very clearly and attractively; panels very well integrated. Affords definite information as to cause of dental decay and malformation impressing necessity of prenatal care, area (enamel) attacked first, correct method of cleaning teeth, value of early and regular visits to dentist; how personal appearance is improved by insertion of dentures. An excellent visual method of emphasizing care of teeth, especially for children."

- " 1. Negative
2. Uninteresting
3. Rather gruesome
4. Poorly organized
5. No participation by observers
6. Exhibit lost a fine opportunity of presenting some fine lessons in practical dental health education."

Social Hygiene Exhibit

"The general idea of presentation I thought was very good as well as being attractive. It makes one conscious of what the community can do for one. The general placing of the institutions was instructional. Exhibits of this type would lead to better health (mental and physical) and a general improved community life. It showed good integration."

"The colors are dull and lack all visual appeal. The name social hygiene, I believe, should be explained to the lay public. It is a somewhat misleading term. Many illustrations are used as a method of conveying information. These are inadequate, due to poor workmanship and lack of sufficient explanation. The name 'social' leads to much confusion on the entire exhibit. The integration of panels is without any logical sequence."

ings: public health workers (112 in number), educators (84), students of medicine or education (66), and professional exhibitors (9); and their ratings tabulated separately. The percentage of agreement in each professional group is shown in Table 2. There is no evidence in that table to indicate that there is any closer agreement when the ratings are tabulated by homogeneous professional groups than when they are considered as though made by a mixed group of professional workers. In only one homogeneous group and for only

one exhibit (the students, in rating *Maternal Health*) was there a majority opinion on a specific exhibit. The same general lack of agreement exists throughout the table.

WHAT THE PUBLIC THINKS OF EXHIBITS

In order to determine whether the reactions of the general public (who, after all, are the ones for whom the exhibits were prepared) were more reliable than the judgments of experts, 18,449 lay spectators also were asked to rate the exhibits. Their instructions

were to check, on a rating form, the exhibits at which they had stopped. On the form were listed the 26 major exhibits which had been rated by the professional workers, and beneath the list were the following instructions:

"Of the exhibits checked above, please list the three exhibits you liked most and the three you liked least."

Spaces were provided for the choices.

Tabulation of their preferences, as shown in Table 3, indicates no direct overwhelming agreements. For only 8 exhibits did more than one-fifth of the spectators express a preference.* It would seem that judgments by laymen are also unreliable as criteria to judge the effectiveness of exhibits.

DO PROFESSIONAL WORKERS AND THE PUBLIC AGREE?

There was also considerable disagreement between the ratings of the professional group and those of the laymen. Of the former, 51.7 per cent rated the *Maternal Health* exhibit as best, but only 11.9 per cent of the laymen gave it the same rating. Similarly, 16.0 per cent of the laymen rated *Glands of Internal Secretion* as worst, whereas only 4.4 per cent of the professionals gave it the same rating. In rating another exhibit (*Tuberculosis*) 28.1 per cent of the laymen indicated it as one of the best, yet only 5.2 per cent of the professional raters made a similar selection.

Thus, there was disagreement among the professional groups constructing, using, and evaluating exhibits; among the members of the public for whom the exhibits were intended; and between those making the exhibits and those for whom the exhibits were made. What, then, is the value of ratings of this type in the evaluation of exhibits?

SUMMARY AND CONCLUSIONS

The increased interest in exhibits and their use for health education warrants an evaluation of their effectiveness if expenditures for exhibits are to be justified. An attempt at such an evaluation of the health exhibits at the New York World's Fair was undertaken in 1939. This paper reports the reliability of ratings as one technic of measuring the value of the exhibits.

In the study reported, 271 professional workers comprising public health personnel, educators, students of education or medicine, and professional exhibitors; and 18,449 lay spectators rated 26 major exhibits. The professional workers designated the three "best" and the three "worst," and the lay raters indicated the three "liked most" and the three "liked least."

On only one of 26 exhibits did as many as half the professional raters agree it was among the three best exhibits shown, and even that one was rated among the worst by 11 of the 271 judges. Only 6 others were rated similarly by as many as one-fifth of the raters. The ratings indicate that the raters' criteria were not consistently applied by the 271 individuals. There was no closer agreement when the ratings were tabulated by homogeneous professional groups (public health, educator, student, or exhibitor) than when they were by the total.

On only 8 of the 26 exhibits did as many as one-fifth of the lay raters express agreement in preferences. Apparently, judgments by laymen are also unreliable as criteria to judge the effectiveness of exhibits.

Consistent with the disagreements found in the professional and lay groups were the differences between the two groups of judges. The raters who normally construct, evaluate, and use exhibits did not agree with the lay public for whom they make exhibits.

With such disagreements among the

* As an example, 2,195 laymen rated the *Maternal Health* exhibit as one of the three best, but 1,531 others rated it as one of the three worst.

raters, it may be concluded that ratings are of little or no value in the evaluation of exhibits. Methods of evaluation which are more valid and reliable and depend more upon the behavior of the spectator must replace ratings, if the true value of health exhibits as educational media is to be appraised.*

Subsequent papers will describe the use of such technics of evaluation as: (1) timing the length of stay at an exhibit and checking it with the time required to read the legends, (2) checking the spectators' statements of the objectives of the exhibit, from viewing it, with the objectives as stated by the

exhibitor, and (3) testing information and attitudes of spectators as they have been affected by exhibits. It is hoped that similar objective studies may be undertaken of the effectiveness of pamphlets, posters, movies, and other accepted health educational technics. Only thus can we assemble the evidence necessary to justify increases in budgets for popular health education.

NEED FOR EXTENSION OF LOCAL HEALTH SERVICE

ATTENTION of JOURNAL readers is called to the report of the Association's Committee on Local Health Units. This report appeared in the April, 1943, issue of the JOURNAL, and is carried under the title, "Units of Local Health Service for All States." It is perhaps one of the most important and significant documents ever published by an Association committee. Here is a statesman-like plan for reasonably adequate local health service in all communities of the United States; a setting forth of broad general principles and objectives. The report represents thinking in terms of the whole and all of its parts, and heralds a consciousness that advance in quality and quantity of public health service rendered in the United States must no longer be limited to a nibbling and chipping process. It insists, too, upon local initiative and responsibility, and recognizes the importance of the private physician and of hospitals in providing public health services.

The committee which submits this report has been working diligently for a number of months. It has carefully analyzed the extent and character of local health service as it at present exists. It has set forth certain ideas which it considers basic and, with these in mind, and in conference with the respective state health officers concerned and with members of the medical profession, has laid down as a preliminary the estimated number of units which probably would be necessary for complete coverage in each state. The results of deliberation along these lines were presented graphically for the several states at the last Association meeting. These maps attracted a good deal of interest and aroused a lot of discussion, which is what was intended. The committee will continue its work by further conference with appropriate officers of state government and with representatives of state medical societies; will analyze existing state laws bearing upon establishment of local health services; and will study further the costs and personnel needs which should on the average be met in jurisdictions of one size or another.

The committee will, of course, encounter difficulties in the development of its program, but these are to be expected. Thus the committee advises adminis-

trative districts that would in some instances cut into and across existing civil jurisdictions. Members of state legislatures and local office holders are inclined to look upon this sort of suggestion as political dynamite, and will invoke in full measure the sanctity of tradition and local autonomy. Further difficulty will be encountered in obtaining legislation that will permit or require provision of health service as a function of local government. The permissive type of law is more readily passed by a state legislature, and in fact exists in many states, but it leaves much to be desired. With such a law, local authorities must first be persuaded to decide upon and pay for health service and from then on, even though performance is competent, the local service constantly stands in jeopardy of discontinuance because of local decisions which have but little to do with the merits of the case. No community would think of discontinuing schools because an influential local group disliked the Superintendent of Education, but this can happen and has happened in new ventures in public health. In contrast to the permissive legislation, a law requiring that local jurisdictions provide and expend money for local health purposes would be more difficult to get through the state legislature but this type of law is probably, in the last analysis, a very necessary instrument if health service coverage is to be complete and continuing. Finally, the plans of this committee will undoubtedly receive some opposition from some of the state health officers. Part of this will be justified and part of it unjustified. State health officers as a genus do not like to have persons in remote places, perhaps behind desks, tell them how to organize and administer public health work in their respective states. In many instances in the arguments that will ensue, this state health officer or that one will be right and the committee will be wrong, for the latter cannot know of all the complexities in each locality. Opposition on this basis will be constructive for, in the long run, divergence in detail as to districting, organization, and administration, will tend to prevent too rigid a pattern and stagnation. On the other hand, there ought to be no opposition to general principles if those principles are sound. On this point, one is encouraged by the background and character of the persons who make up the committee. They possess both technical knowledge and long administrative experience.

If the plan of the committee has any inherent weakness, it is that it visualizes only present conventional public health service, taking no cognizance of the fact that the health department of the future is quite likely to be concerned with medical service of one form or another. Health officers are loath to consider this for, while few of them can give undivided support to the thesis that all is well with today's medical care, most of them distrust measures tending toward a socialization of medicine. Further, they know from past experience that in any combination of medical service and conventional public health activities there is likely to be trouble in administering the first and a probable atrophy and disruption of the second. The committee may have been wise in avoiding this question, which is of itself a major issue. To include it certainly would complicate the picture, diffuse the objectives, and increase the opposition.

Be all these things as they may, we urge that JOURNAL readers become detailedly familiar with this report of the Committee on Local Health Units; that members of the Association become apostles for the general idea of complete coverage of the nation by adequate full-time local health service under government auspices; and that the committee continue its good work.

THE DEATH OF DR. A. GRANT FLEMING

DR. ALBERT GRANT FLEMING, Professor of Preventive Medicine and Public Health, McGill University, died in Montreal on April 9 after some months of illness. His death was not unexpected, but this does not lessen the sense of loss of those who knew him or knew of his work.

Dr. Fleming was President-Elect of the Canadian Public Health Association, and in the American Public Health Association he was a member of the Governing Council. In 1939 he served as Vice-President of the latter Association. In the last war he won the Military Cross for gallantry under fire, and at the time of his illness was scheduled to head the section of preventive medicine in the Canadian Army. He received the King's Jubilee Medal in 1935 and won the Coronation Medal in 1937. In the period 1936-1940 he was Dean of the Faculty of Medicine in McGill University, and since 1928 was Director of the Department of Preventive Medicine and Public Health in that Faculty.

This record and these accomplishments did not arise through accident, for Grant Fleming possessed a rare combination of medical competence and sound administrative ability. Exhibiting in finest measure the caution of the scientist and the vision of those who see beyond today, he was equally comfortable in laboratory and debate; and, endowed with an unusual personal graciousness, he could be forceful without dogmatism, could disagree without being disagreeable.

With our Canadian colleagues we share in the loss of a leader in the field of public health; and with the people of Canada we sympathize in the death of one of her public health statesmen.

THE U. S. PUBLIC HEALTH SERVICE IS COMMENDED

SOME two months ago there appeared in the *Washington* (D. C.) *Post* an article entitled "Crackdown on Vice Scatters Disease-Bearers." This was written by Agnes E. Meyer and is one of a series in which the author reports shrewdly and frankly upon conditions existing in centers of war activities. It is not, however, the series as a whole or the findings set forth in this article with which we are concerned, but rather with an excerpt from it. This is in reference to the U. S. Public Health Service, and is as follows:

"Mayor Devin's (Mayor of Seattle, Washington) words of gratitude to the United States Public Health Service expressed a feeling that has been growing steadily in my own mind as I traveled through the country. Wherever I have encountered members of this Federal department whether in central positions or in the most remote outposts of our social battle line, I have found such a uniformly high quality of character and ability, such passionate and fearless devotion to unending duties, that it seemed to me as if the highest manifestation of unselfish idealism is manifest today among the men of science."

Mrs. Meyer, who is the wife of the publisher of the *Post*, is known as one who does not make this sort of comment without careful and skillful weighing of evidence, and it is therefore particularly gratifying that she pays such a tribute to a great Service. Many of those engaged in public health work, and the federal government in particular, are inclined to take the U. S. Public Health Service for granted, tend too much to believe that it is just another government bureau; and Congress, under the pressure of military necessities, is likely to lose sight of how

competently and quietly the Public Health Service has met the multifold and complex problems imposed upon it by the war.

The qualities of skill and devotion to duty in these Public Health Service officers whom Mrs. Meyer met are to be expected. They have been carefully trained and thoroughly indoctrinated in the fine traditions of the U. S. Public Health Service. They are thus conscious not only of duty but of responsibility to maintain the justly-acquired prestige of the organization they represent. And, too, their very presence in the various mushroom communities in military and industrial areas of the country where Mrs. Meyer met them indicates forehandedness and intelligent planning on the part of the Surgeon General and his staff. Not only are these Public Health Service officers concerned with control of venereal diseases, but with malaria control, industrial hygiene, with measures directed against typhus fever and plague, with control of stream pollution, acute communicable disease control, with strengthening local and state programs against tuberculosis, and with the day by day task of building up ordinary routine health services. One encounters them, too, in Public Health Service research laboratories; as medical officers for the Coast Guard; in Marine Hospitals; and in a few unusual and distressing situations where the loss of physicians has created an emergency, one finds them temporarily rendering actual medical care.

The remarkable aspect of this participation of federal health officers in state and local health work is that there has been no complaint of invasion of states' rights, no usurpation of local authority, no friction. On the contrary, they have been requested, welcomed, and relied upon. They are well oriented as to the ethics and legalities of the situations in which they find themselves and of the limits of their authority as federal officers; and state health officers, through years of cordial relationship with the Public Health Service, have come to trust the wisdom and integrity of that Service.

We set these matters forth with two things in mind. The first is to concur in Mrs. Meyer's words of praise of the Public Health Service; and the second is to reëmphasize, to the medical profession and other public health workers, and to the public, that this organization is the logical federal agency around which to build national health programs in both war and peace.

LETTERS TO THE EDITOR

TO THE EDITOR:

Under existing conditions with fluid milk shortages in the offing, it is more desirable than ever to have a uniform milk code to be able to shift milk supplies over a wide area. The *U. S. Public Health Code* is generally advanced for this purpose.

The main difficulties with the *U. S. Public Health Code* are no provision for the detection and elimination of thermophilic and thermoduric bacteria contamination of milk by dirty utensils and the lack of personnel and transportation for such farm inspection, and the lack of material and labor for such changes as the inspection would indicate. Also there is no guarantee that milk produced under adequate conditions would be of adequate quality.

The milk code of the Boston Health Department could serve. This code is based on continuous inspection of the quality of the milk as it arrives at the creamery, rather than on production conditions, as determined by one farm inspection a year.

1. A sample of each farmer's milk must be taken once a month and analyzed as follows:

- a. A Breed smear for approximate raw count and presence of udder infection.
- b. Laboratory pasteurized count—plated at 32° C.—for washing and sterilizing of equipment.
2. If the count is over 400,000 raw or 20,000 pasteurized, an official warning is sent the farmer.
3. A recheck must be taken in 10–15 days. If the 2d sample is high, the farmer is shut-off until a check sample is found to meet requirements.

In actual operation it is the responsibility of the country plant manager to visit the farmer after the first high count to insure against a second high count for a shut-off.

Centralized laboratory facilities could simplify the operation and supervision and reduce expenses. In most cases existing laboratory facilities can be converted to cover large areas adequately.

Any milk under 400,000 raw, 20,000 pasteurized and free from all udder infection as insured by laboratory analysis would meet approval from most milk inspection authorities.

THEODORE MARCUS, M.Sc.,
Dorchester, Mass.

THE following letters bring to a close the discussion of certain points, statistical in nature, raised by Mr. H. M. C. Luykx of New York University College of Medicine. Mr. Luykx' letter appeared in the April issue of the JOURNAL.

TO THE EDITOR:

The comment of Mr. Luykx on the convention of attaching a measure of sampling error to a statistic by means of a \pm sign, and his speculation concerning probable interpretation of it, is interesting from many points of view. There would probably be complete agreement that it should always be stated whether the measure following

\pm is a "probable error" or a "standard error." And there can be no question but that there is need for clearer understanding of how the error measures are correctly to be interpreted, particularly in view of the wholly erroneous statements repeatedly occurring in a very recent textbook on vital statistics. But there is likely to be conflict of

opinion on the view that "the use of the \pm following an average is distinctly undesirable," especially when supplemented by the view that a careful reader would "make it his business to understand the meaning of standard error." The reader is not likely to become careful just because a \pm sign is not there! Intellectual laziness may indeed be encouraged by a sign which obviously indicates an error range of some sort, but surely only in those not likely to be aroused by the presence of a substitute expression.

The question to this writer frames

itself somewhat in this way: Isn't there more to lose than to gain by dispensing with a sign which even the uninitiated realize immediately indicates a measure of uncertainty? His personal opinion at present is definitely in the affirmative. But let us be careful to define our measures and to understand them, without which no form of statement will be of much avail.

ALAN E. TRELOAR,
Associate Professor of Biostatistics,
University of Minnesota Medical
School

TO THE EDITOR:

Several points are raised by the comments of Mr. H. M. C. Luykx.

1. The "Epidemiologic Note" in the January issue of the *American Journal of Public Health* stimulating the comment of Mr. Luykx has been taken from material in the summary of the original article appearing in the November 14, 1942, issue of the *Journal of the American Medical Association*. Discussion of statistical procedure should have been directed preferably to the author, who knows best of all what he did and why, or at least to the organ publishing the original material.

2. Had Mr. Luykx reconstructed the calculations based on the data presented in the original article, he would have found the \pm attachment to be the *standard* error of the mean and *not* the *probable* error on which the commentator makes so detailed an explanation.

3. It is a well known fact that the standard error is a more acceptable measure than is the probable error. For that reason common agreement almost tacitly assumes a \pm attachment to be the standard error without so designating it. The user of the probable error, because he is departing from accepted

procedure, carries the burden of an explanation. In the illustration at issue the observer is well within accepted practice. However, because, as Mr. Luykx points out, there are some readers who could be misled, it might have been desirable for the author to have stated, perhaps in a footnote, that the \pm attachment used was the standard error of the mean.

4. Since Mr. Luykx believes the \pm attachment is usually the probable error and has made his comments on the interpretation of the probable error, in order not to mislead the reader who participates in this controversy I shall continue with the probable error. I accept the comments offered by Mr. Luykx in his third paragraph, stressing, however, that the average of 12.2 days is the *obtained* or *observed* mean. With the *one* probable error attachment the *true* average lies somewhere between 11.1 days and 13.3 days on odds of 1 to 1. On odds of 22 to 1 the true average lies somewhere between 8.9 days and 15.5 days which are the limits set by the obtained mean of 12.2 days and three probable errors [$12.2 \pm 3 (1.1)$].

5. I do not accept the comments offered by Mr. Luykx in his fourth

paragraph. The ± 1.1 days are a constant calculated from the *observed* mean of 12.2 days and should not be used with any of the limits set by this observed mean and its \pm attachments such as to the 8.9 days or the 15.5 days, as if these limits again were *observed* centers or means. The ± 1.1 days belong to the observed mean of 12.2 days. The statement made by Mr. Luykx actually describes the limits set by the observed mean and *six* probable errors [$12.2 \pm 6 (1.1)$]. The error measures are attached to observations. The ± 1.1 days describe the amount of fluctuation inherent in sampling, the amount which by chance alone one can expect the observed mean of 12.2 days to vary.

Sampling errors, preferably *standard* errors should be stated with their observed measures. As long as there is a

remote possibility for confusion it might be desirable to mention whether a \pm attachment is the standard or the probable error with a statement that the *observed* measure and its attachment sets the limits within which by chance the *true* measure will lie. However, I believe, the reading public is becoming sufficiently conscious of sampling and of the use of a \pm attachment as referring to the standard error that a detailed explanation is unnecessary. The uninformed but interested reader will consult the reference for that explanation, thus relieving the observer of the responsibility of incorporating statistics instruction in his article.

MARGUERITE HALL, PH.D.,
Assistant Professor of Public
Health Statistics,
School of Public Health,
University of Michigan

TO THE EDITOR:

Mr. Luykx appears to dislike the use of the " \pm " notation to indicate the measure of sampling error to be attached to a statistical constant. Except for the fact that this notation is sometimes used for other kinds of errors, this writer sees no objection to it. Certainly it should be clearly indicated what measure of sampling error follows the " \pm ." It is not apparent why one might prefer the standard error (S.E.) to the probable error (P.E.), except that the latter requires the additional step of multiplication by .6745. Since the limit of sampling error is often taken as 2 S.E. (or 3 P.E.), it would be in harmony with this usage to attach this measure.

As Mr. Luykx says, working on the

assumption of a normal sampling distribution, the true value of the corresponding statistical constant of the universe may readily differ from that observed by as much as 3 P.E. in either direction. It does not follow that the constant for another comparable series of observations can differ as readily by 6 P.E. from that observed. Indeed, if another series gave us the same P.E. (as it should *theoretically*) then P.E. of the difference would be $\sqrt{P.E.^2 + P.E.^2}$ or $P.E.\sqrt{2}$ and a difference of 3 P.E. $\sqrt{2}$ or 4.24 P.E. might be adjudged significant.

Professor of Biostatistics,
De Lamar Institute of Public
Health, Columbia University

REPORTS OF COMMITTEES

The By-Laws of the American Public Health Association provide that no standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council. Except where specifically noted to the contrary, the following reports are in the nature of progress reports from committees, most of which have had Section approval, but which have not been presented for Governing Council action, and therefore are not to be interpreted as standards approved by the American Public Health Association.

Disinfection of Dishes and Utensils

Engineering Section

YOUR committee on the washing and disinfection of dishes and utensils submits herewith a brief progress report of such work as it has been possible to do under adverse conditions this year.

Last year the committee reported on a survey of dishwashing machines as they were being operated in public eating establishments. The report showed a general lack of uniformity in turning out visually and bacteriologically clean dishes. This was not surprising in view of the observed lack of control of wash and rinse water temperatures, the times of washing and rinsing, and the concentrations of detergent.

Among other things, further study was suggested to determine the optimum ranges of these and other factors that would tend to give more satisfactory efficiency of operation. The data obtained served to emphasize the importance of controlling these important factors within certain limits.

In continuing work this year, the committee planned to develop a standard soiling material consisting of mixed foods that could be applied to standard dishes with a view to having the

percentage removal of such soil indicate the degree of effectiveness of the washing operation. It was desired to make this soil just difficult enough to remove so that the dishes containing it, when properly racked in a good machine functioning as it should with fresh wash water at optimum temperature and containing a fair concentration of a good detergent, would lose the soil in 1 minute.

Using such dishes intended to be uniformly difficult to clean it should be possible, with a machine especially equipped to permit changing temperatures and other factors at will, to study the effect of varying each factor while maintaining the others constant. The amount of soil remaining could be determined approximately by comparison with a set of standard dishes containing fractions of the amount of soil placed on the test dishes.

Such dishes also should serve to show a comparison between the efficiency of various dishwashing machines as operated in public eating establishments. Valuable information also could be obtained by comparing such results with those secured in the same ma-

chines under more favorable operating conditions.

Most of the limited time available this year has been devoted to experimenting with combinations of foods to make a soil to fill this specification and with methods of drying such soils uniformly.

It became apparent that greases could be removed readily by hot water alone as could such substances as egg, milk, and flour unless very thoroughly dried. At first drying was done in an oven at 105° C. for 1 hour.

Tests showed drying to be quite a critical factor. Tests with plates in similar positions, other factors being constant, showed variable results. Considerable work was required to get uniform drying throughout the film on each dish and uniformly on every dish. Oven drying, even with agitation of the air by a fan, did not prove satisfactory. Finally a device was made to introduce a large volume of air heated to about 135° C. tangentially into a cylindrical chamber of slightly larger diameter than the dish to be dried and just below the soiled surface of such inverted dish. Dishes dried in this manner for 2, 4, and 6 minutes respectively showed little variation. A drying time of 4 minutes at this temperature appears to give satisfactorily uniform drying after the soil has dried overnight at room temperature. This is time consuming as each dish must be treated separately.

When the drying factor was variable it was impossible to standardize the soil. With that factor now fixed it should be possible to develop a satisfactory soil in a short time to permit work along the designated lines to be undertaken during the coming year.

The work this year also included some observations of dishwashing machines in operation with a view to determining weaknesses both in construction and operation. Some of the

outstanding points are discussed below.

Most wash tanks are not so designed that all surfaces can be easily cleaned. The immovable superstructure frequently interferes with the operator reaching and viewing the inner surface of the tank. There are sharp angles to hold dirt and obstructions such as tray or belt conveyor angle irons, pipes, and bolts. Particles of putrescing food adhering to the walls of the tank when it is emptied pollute the next batch of wash solution.

The design of pumps also is such that they cannot be cleaned easily and they also contribute to the collection of decaying food solids.

The use of easily disassembled sanitary pipe lines also would improve conditions by making it easier to keep the pipes and jets clean and functioning properly.

A number of instances have been observed in which the hand operated valve controlling the supply of water to the wash tank was leaking badly. These valves often are placed so that the handle projects into the working space where it is bumped by trays or other objects. The wheel handles are broken off and the stems become rounded so that the handle slips, making it difficult to close the valve tightly. The valve seats also corrode. On one machine the valve was in such condition that the operator could not close it and a stream of water ran continually through the wash tank. Under these conditions the detergent added was promptly diluted beyond the point of usefulness. A large quantity of hot water also was wasted. The use of good valves such as stainless steel seated globe valves on these water lines properly placed to protect the handles would improve conditions.

Some washers have revolving spray arms mounted on brass bearings. Sometimes these bearings bind, resulting in poor coverage of the dishes. In

other instances they become so worn that the leakage reduces jet pressure and volume.

The size and area of spray slots and jets vary considerably in different machines. Some jets are as small as $\frac{1}{8}$ in. in diameter or 0.012 sq. in. in area, while at the other extreme some slots are as large as $\frac{3}{4}$ by $\frac{3}{32}$ in. or 0.07 sq. in. in area. Small jets may serve the purpose of building up pressure at the jets but they clog too easily.

In one single-tank machine the fresh water rinse jets were found badly clogged. The dishes although showing an alkaline residue looked fairly clean. The rinse spray jets were cleaned and the dishes came out noticeably dirtier rather than cleaner than before. The explanation is that the greater volume of rinse water from the cleaned rinse jets diluted the detergent to such an extent as to make washing ineffective. It also may have raised the temperature of the wash water above the optimum.

Strainers usually are cumbersome and hard to remove and clean. As a result they often become bent or broken allowing food particles to enter the pump spray lines where they tend to clog the spray jets.

Some single-tank machines depend upon the hot rinse water and sometimes on an auxiliary gas burner to maintain the temperature of the wash water. As jets clog the quantity of rinse water decreases and temperature drops. Auxiliary gas burners generally do not have sufficient capacity to compensate for normal heat losses. In one machine the

operation of the wash sprays for 1 minute caused a drop in temperature of wash water of 5° F.

This is simply a cross-section of some of the weak points of dishwashing machines that have been observed.

With this summary of the work and observations of the year we suggest the continuation of these investigations and make the following recommendations which are in accord with those made last year:

1. That minimum satisfactory time intervals for washing and for rinsing under fixed operating conditions be determined and that as soon as practical new machines be built to insure such periods.
2. That optimum temperature ranges for washing and for rinsing be determined and when feasible new machines be equipped to maintain such temperature automatically.
3. That new machines be designed to prevent excessive dilution of the detergent in the wash water and more satisfactory methods be devised for maintaining the concentration of detergent.
4. That more attention be given to sanitary construction and ease of disassembling machines for cleaning.
5. That further studies be made along the lines herein suggested to determine if possible just what dishwashing machines are accomplishing or failing to accomplish in the cleaning of soiled dishes.

The committee wishes to acknowledge the active assistance of Clarence W. Weber in testing and observing equipment.

Microbiological Examination of Spices, Fermented Foods, and Fruit Juices*

Food and Nutrition Section

THE committee has continued the program of bringing together each year a few practical methods for the examination of foods with a view to compiling eventually enough material for a publication on Standard Methods for the Microbiological Examination of Foods.

Microbiological Examination of Spices

The bacteriological examination of spices is important since they are used as ingredients in many types of prepared foods. It is known that most types of spices are very high in bacterial count¹ and thus may contribute to the spoilage of the food products in which they are used, as for example, in such products as meats of low process such as luncheon meats, sausages, etc.² It is because of the importance of such spoilage problems that the committee believes that a standard method for the bacteriological examination of spices should be proposed.

Spices may be divided into "whole spices," such as allspice, cloves, cinnamon sticks, etc.; "ground spices," such as pepper, coriander, ground cloves, etc.; and spices of bulky nature such as bay leaves, herbs, sage, etc.

METHOD

Sampling—Take a 50 gm. sample from each of three containers and pack carefully in glass jars to prevent loss of oil, and send to laboratory.

Preparation of Samples for Culturing—Weigh spices on sterile paper or directly into the dilution flask in a dust-free room or

cabinet. Due to differences in bacterial counts, bulk and character the following amounts of spices are recommended:

Whole spices	10 gm.
Bulky spices	2 gm.
Ground spices	1 gm.

Add sterile water to spice to 100 ml. mark and shake vigorously for 5 minutes. Allow coarse material to settle out and use appropriate dilutions in various media.

Making Bacterial Counts—Counts should be expressed as numbers of bacteria, molds, spores, etc., per gm. of spice.

a. Total bacterial count:

Use either nutrient agar (Difco) or Brom-Cresol Purple-tryptone-glucose agar (Difco) and incubate for 48 hours at 37° C. and 55° C.

b. Acid-tolerant bacteria and molds:

Use wort agar (Difco) and incubate at 25° C. or room temperature for 5 days.

A special agar of the following formula may be used for the detection of *B. thermacidurans*:

I. Proteose peptone	5 gm.
Yeast extract	5 gm.
Glucose	5 gm.
K ₂ HPO ₄	4 gm.

Dissolve above ingredients in 500 ml. of distilled water and adjust to pH 5.0 and autoclave.

* Report of the Committee on Microbiological Examination of Foods.

II. To another 500 ml. of distilled water add 20 gm. of agar and autoclave.

Mix the contents of flasks I and II just prior to use.

Incubate plates at 37° C. and 55° C. for 2 days.

Detection of Spores—Boil spice suspensions for 5 minutes and make up loss due to evaporation with sterile water. Plate appropriate dilutions using: (A). Brom-cresol purple-tryptone-glucose agar and incubate at 37° C. and 55° C. for 2 days. Report total spore count, flat sour spore count and non-flat sour spore count; (B) For the detection of spores of aerobic gas producing bacteria use Jensen's medium* and incubate at 37° C. or 48.9° C. for 5 days. (More rapid gas production will be obtained at the higher temperature.)

Anaerobes

a. For putrefactive anaerobes use liver broth medium⁴ stratified with agar and incubate at 37° C. for 5 days;

* Jensen's Medium: Fill culture tubes half full with finely ground or chopped spiced ham (from a sound can) and wet down with solution made of 0.4 per cent sodium nitrate and 2 per cent sucrose. Autoclave at 15 lbs. pressure for 15 minutes.

NOTE: (a) No trapped bubbles of air should appear in the medium. (b) Medium should be covered with at least ¼ in. of water. (c) Tubes should not be more than half filled.

b. For thermophilic anaerobes not producing H₂S use liver broth medium⁴ stratified with agar and incubate at 55° C. for 48 hours. The liver broth should be freshly exhausted prior to use.

c. For thermophilic anaerobes producing H₂S use the following medium (a modification of 5):

Tryptone, Difco	10 gm.
Na ₂ SO ₄	1 gm.
Agar	20 gm.
Water	1,000 ml.

After the above ingredients have been dissolved by boiling, add 10 ml. of a 5 per cent solution of ferric citrate. Tube in 10 ml. amounts and autoclave at 15 lbs. pressure for 30 minutes. Use appropriate dilutions of spice and incubate at 55° C. for 48 hours.

Microbiological Examination of Fermented Foods

There are a number of different types of fermented foods which might be considered under this heading. The methods to be discussed in this section do not deal with dry products which have undergone fermentation during preparation, such as coffee, tea, cocoa, etc., nor with fermented beverages such as beers, wines, etc. Rather they apply to fermented products such as sauerkraut, pickles, olives, and okra either as raw or as processed products. Of these, sauerkraut is the only one which is not materially changed after the fermentation process, that is, by sweetening, spicing, or similar pickling change.

Sauerkraut is normally sold as a processed food or as a raw product. It

may be abnormal in several ways some of which may lead to an abnormal microbial flora. Usually such conditions are caused by faulty salting or improper temperature of fermentation, and may cause an improper acid development. With this in mind it seems essential that after superficial examination of the food, analysis for total acidity and salt should be made.

The more common undesirable microbial changes occurring in fermented foods are due to yeasts. Since excessive numbers of yeast cells, mold hypha, or Gram-negative rods are indicative of an abnormal condition, a microscopic examination of a Gram-stained preparation is desirable.

The direct microscopic method

(*Standard Methods of Milk Analysis*, 8th Ed., 1941, pp. 40-53) should be used. Brine from the product should be mixed, and a 0.01 ml. sample spread over a 1 sq. cm. area. After drying, the preparation is fixed with heat and stained with Gram's stain. A high count of Gram-positive rods and cocci should be expected and is desirable, since they are the bacteria responsible for a normal fermentation. A high yeast count or presence of mold hypha is indication of faulty conditions such as excess salting, exposure to contamination from the air, or drying of the surface.

The total plate count has little significance in indicating the condition of raw kraut. It is used primarily for isolation of organisms from the kraut but it may also be used to study the types of colonies developing upon the plate.

Processed kraut or pickles sometimes may be given too little process or may become recontaminated. Plating may be used to demonstrate this contamination.

Processed sauerkraut or pickles should contain no microorganisms. The raw products will contain large numbers of organisms, the colonies being small, gray white, round, 1-3 mm., or lens-shaped subsurface colonies or

larger, 3 mm. surface colonies. The presence of larger white or cream-colored colonies or smaller colored colonies indicates an abnormal product.

PLATING METHODS

All equipment (pipettes, dilution bottles, Petri dishes, hot air ovens, autoclaves, thermometers, incubator, water, peptone, agar, and sugar) used for bacteriological examination of juice should meet the specifications of the A.P.H.A. *Standard Methods of Milk Analysis* (8th Ed., 1941, pp. 16-22). Yeast*

	Per cent
Agar, best quality, granulated or shred	1.5
Yeast extract, Bacto or equivalent	0.3
Tryptone, Bacto or equivalent	0.5
Glucose	0.1
Water, distilled	
Adjust reaction to pH 6.6 to 7.0	
Sterilize in an autoclave	

extract should be used rather than beef extract.

Plating—Melt the agar in an autoclave, in flowing steam, or in boiling water. Cool to 41-42° C. and hold at this temperature until ready to pour into Petri plates.

The juice of the fermented product should be mixed thoroughly, especially from top to bottom.

For processed food prepare Petri plates in duplicate containing 1 ml. and 0.1 ml. of juice.

For raw products plate at dilutions of 1:10,000 up to 1:1,000,000. Pour approximately 10 ml. of agar in each plate and mix by rotating gently. Cool, invert plates and incubate at 32° C. for 48 hours.

* Use tryptone-glucose-yeast extract agar of the following composition:

Microbiological Examination of Fruit Juices

The processing of fruit juices is a relatively new industry in many ways but one which will require close supervision in order to control the quality of the products. Control of quality is essentially a control of cleanliness and handling of the food in the plant.

METHOD

The agar plate method of examination of fruit juices may be an aid in determining the quality. The method for estimating microorganisms consists of counting the microbial

colonies or growths which develop upon a nutrient agar plate after mixing and incubating a suitable dilution of the juice. The colonies are counted after incubating for 72 hours at 32° C.

All equipment (pipettes, dilution bottles, Petri dishes, hot air ovens, autoclaves, thermometers, incubator, water, peptone, agar, and sugar) used for bacteriological examination of juice should meet the specifications of the A.P.H.A. *Standard Methods for the Examination of Dairy Products* (8th Ed., 1941, pp. 16-22). Yeast extract should be used rather than beef extract.

Use tryptone-glucose-yeast extract agar of

the composition given under fermented foods and/or a more acid medium as suggested for *B. thermoacidurans*.

Plating—Melt the agar in an autoclave, in flowing steam, or in boiling water. Cool to 41–42° C. and hold at this temperature until ready to pour into Petri plates.

From the viewpoint of method of examination and of interpretation of results, fruit juices should be considered as of three types:

(A) Pasteurized, (B) raw, and (C) frozen or cool storage.

Pasteurized juices should be relatively free of microorganisms.

Before opening, examine the container, the contents of the container, as well as the closure for signs of fermentation or mold growth. Abnormal cans may show loss of vacuum or even hydrogen swells. Bottle caps may bulge due to fermentation.

Mix the contents by inverting several times.

Open bottles while passing a flame over the cap.

Open cans after burning alcohol over the top.

With a pipette delivering 1.1 ml., prepare in duplicate, Petri plates containing 1 ml. and 0.1 ml. of juice.

Pour approximately 10 ml. of agar in each plate and mix by rotating gently. Cool, invert plates, and incubate at 25° C. for 72 hours.

Raw juices will always have much higher counts of microorganisms.

Observe juice for fermentation or for mold growth.

Mix the contents by inverting if in bottles, or by stirring if in larger containers.

Prepare dilutions from 1:100 up to 1:10,000 in duplicate in Petri plates. Pour agar, rotate, cool, and incubate as directed above.

Frozen or cool storage juice when freshly packed might be considered as raw juice. During storage certain types of microorganisms die, while others accustom themselves to low temperatures.

Examine the surface of the juice for mold growth. Thaw and mix the juice immediately. Plate at dilutions of 1:100 to 1:10,000. Pour agar, rotate plates, cool, and incubate at 21° C. for 5 days. Better results will be obtained at this temperature on frozen and cool stored juices. Examine after 2 days and 3 days, and count the plate if it becomes apparent that mold or spreading bacterial colonies may spread over the plate.

INTERPRETATION OF RESULTS

Counts on pasteurized juices must necessarily be low in order to insure keeping quality, but spore-forming bacteria and mold spores often survive pasteurization, especially if the products have not been handled properly. Plate counts up to 5 per ml. may be expected. Mold or bacterial colonies in excess of 10 indicate faulty washing of fruit and cleaning of equipment, or inadequate processing.

In raw juices the total number of organisms is an indication of the cleanliness of equipment as well as the age of the juice. Total counts in excess of 100,000 per ml. may indicate growth during the handling of fruits. High mold or bacterial counts are indicative of poorly cleaned equipment. A high yeast count is an indication of fermentation.

Frozen products are similar to raw juices, although a reduction in count should follow prolonged storage. An excessive yeast count may indicate growth of yeast during a slow freezing operation. Occasionally mold growth or yeast growth may take place during cool storage if the temperature rises somewhat.

A New Method for Measuring the Quality of Urban Housing

A Technic of the Committee on the Hygiene of Housing *

THREE years ago the committee undertook to develop a method of measuring the quality of housing in urban slums. The direct stimulus for the committee's work in this field of appraisal was a number of requests from public health officials that we translate the substance of our "Basic Principles of Healthful Housing" into a yardstick of housing deficiencies, as a basis for enforcement work in problem areas. Although other survey procedures have been developed for city-wide application—such as the standard real property inventories and the 1940 Housing Census—more intensive methods are clearly needed for limited areas which are known to be generally substandard or of marginal quality.

The dramatic slums of any community are likely to be well known in a general way, but this is not enough. Effective programs of control (or post-war rehousing on the scale generally anticipated) will require closer definition and measurement of substandard housing than is possible with present appraisal methods. Such definition and measurement is needed both to delimit the problem areas, to evaluate their deficiencies, and to indicate whether a solution lies in the direction of law-enforcement, demolition and rehousing, or ultimate conversion from residence to

other uses. The standard city-wide survey technics are not designed to provide this type of information.

Although relatively close measurement is needed, this does not mean a researcher's type of survey, turning out bushels of tabulations and acres of maps on every aspect of the problem that might conceivably be of interest to other research workers; rather it means an administrator's inventory, producing only the data needed for policy-making and concrete action—and these data in concise graphic form that will command the attention of already overburdened public officials.

The committee believes that appraisals of a type which will answer basic questions of housing policy can be made by the permanent inspection staffs of health departments and other city agencies concerned with housing. If so, the procurement and interpretation of essential housing data can become a regular function of city governments rather than a job to be done at those rare intervals when special research funds and personnel may be available.

American cities devote thousands of man-days every year to housing inspection service in their slums, but it is a rare community in which this effort provides usable answers to the questions on which a long-term housing program must be built. Such questions, for example, as: Just what is the size and nature of the extreme slum areas? How much worse is district A than dis-

* Adapted from a paper presented for the committee by Allan A. Twichell, Technical Secretary, at the Seventy-first Annual Meeting of the American Public Health Association, St. Louis, Mo., October 28, 1942.

strict B, and in what respects? How many dwellings should be designated unfit for habitation, and either demolished or rehabilitated? Aside from the condition of dwellings, are the problem areas, as neighborhoods, fit to live in?

An experienced city manager has recently pointed out some of the chief reasons why traditional methods of housing inspection fail to supply the needed answers.¹ He cited the common practice of inspecting only on complaints, the waste of effort through unnecessarily overlapping inspections, and the absence of an official minimum dwelling standard to which both enforcement and rehousing programs might be related. Other limitations can be added. Forms and records are seldom designed to be useful or understandable to others than the inspection agency. There is usually no central clearing-point for essential housing data. Often too little thought is given to summarizing inspection findings as a measure of the total problem in areas which are large enough to be significant for planning.

The Committee on the Hygiene of Housing has sought to overcome these limitations in its method of inspection and evaluation. This method has been developed and tested by a Subcommittee on Appraisal of Residential Areas, under the leadership of Rollo H. Britten of the U. S. Public Health Service.* The principal test surveys have been made in New Haven, Waterbury, and Stamford, Conn., in coöperation with public health, housing, and city planning agencies of these cities, and with both technical and financial help from the Connecticut Department of Health. The object of the following

discussion is to describe the appraisal method thus developed, to illustrate the type of results it will produce, and to sketch its implications for local housing policy.

THE COMMITTEE'S APPRAISAL TECHNIC

The central purpose of the committee's method is to make it possible, by assigning a part of inspectorial energies to the systematic appraisal of known problem areas, to measure the quality of housing in a way which will serve the policy-making purposes of all local agencies concerned with housing. The principal features of the technic are as follows:

1. It reports and evaluates housing deficiencies which may adversely affect health, safety, or essential livability.

Factors covered for dwellings include water supply, sewage disposal, toilet and bathing facilities, condition of repair, safety of egress, adequacy of daylight, type and distribution of heating facilities, sanitary condition of the premises, completeness of landlord services in multiple dwellings, room sizes, overcrowding, rent, family size and composition, and family income. In presenting the results, distinction is made between relatively fixed physical conditions and the changeable factors of occupancy and maintenance, since remedial action must recognize these characteristics.

2. The neighborhood environment, largely ignored in previous survey methods, is recognized as an essential element in housing adequacy.

Neighborhood criteria include crowding of land by buildings, industrial and commercial uses intermixed with residence, hazards associated with streets and nearby railroads, adequacy of public utilities, and availability of essential community services: schools, transportation, parks and playgrounds.

3. The quality of housing is measured by a tested system of numerical scores.

Scores are expressed in terms of the dwelling conditions, neighborhood characteristics and these two combined. Instant comparisons of quality are thus made possible as between blocks or groups of blocks, individual dwell-

* Other personnel of the subcommittee: Frederick J. Adams, F. Stuart Chapin, Andrée Emery, Alfred H. Fletcher, L. M. Graves, M.D., Maynard W. Meyer, Robert B. Mitchell, M. Allen Pond, Allan A. Twichell, Secretary, Anatole Solow, Research Associate.

ings, types of dwellings, or other wanted categories.

4. Clear, well designed forms are provided for data collection. Systematic procedures for analysis and graphic presentation of the significant findings are an integral part of the technic.

Items calling for subjective judgment by the inspector have been replaced by those of an objective, measurable type which will give consistent results from different enumerators. Sampling is used when this is appropriate to the purposes intended.

5. The method is suitable for execution by the regular personnel of city departments, after brief instruction.

The appraisal of dwelling conditions is particularly adapted for execution by the inspection and clerical staffs of local health or building departments. The survey of neighborhood characteristics can be made by the staff of an active city plan commission, or under the direction of a sanitary engineer or the technical director of a housing authority. Either the dwelling appraisal or that of the environment can be made alone, but the soundest results are obtained when both are made, for only the combined results give a true picture of the total housing problem.

The scoring system is the distinctive feature of the method, and lies at the heart of its effectiveness. The obvious value of a scoring system is that it *measures* total quality and expresses this measurement by a convenient index figure. There is almost no kind of analysis of housing data which is not tremendously facilitated by the use of scores. But the scoring system must be sound. Much of the committee's work during the period of development has gone into tests of the scoring method. This testing has convinced the committee and numerous outside critics that the present rating scales are accurate differentiators of housing quality.

The scores consist of penalty points assigned to conditions which fall below reasonable standards. These standards,

largely derived from the "Basic Principles of Healthful Housing," have been checked with local officials as to their reasonableness for enforcement or other official purposes. Scoring is done from the completed schedules in the office rather than in the field, for it is believed that the enumerator should report conditions only, and should not complicate either his work or his attitudes by the assignment of ratings. While the standard rating scale is believed applicable in most particulars to any American city, it can easily be modified to fit local or regional conditions, since the rating forms have been developed separately from the enumeration schedules.

The recommended rating scale provides penalties for various deficiencies ranging from 1 to 30 points, depending on the seriousness of the conditions as a threat to health, safety, or essential livability. "Basic Deficiencies"—conditions any one of which may make a dwelling substandard for enforcement or rehousing purposes, such as totally inadequate fire-escapes or the absence of inside toilets—are counted separately as a kind of auxiliary score.

Under this scheme, dwellings and neighborhoods which are essentially up to standard will show penalty scores of 0 points. Extreme slum sections in the cities of our test surveys have incurred total dwelling penalties of 200 points or more per dwelling unit, with characteristic total scores for the neighborhood environment running around 125 penalty points per block or street frontage.²

A JOINT STUDY TO SHAPE OFFICIAL POLICY

The technic was originally intended for execution by local health departments. It soon became evident, however, that such a method could serve the needs of other bodies too, and that it would be most valuable when car-

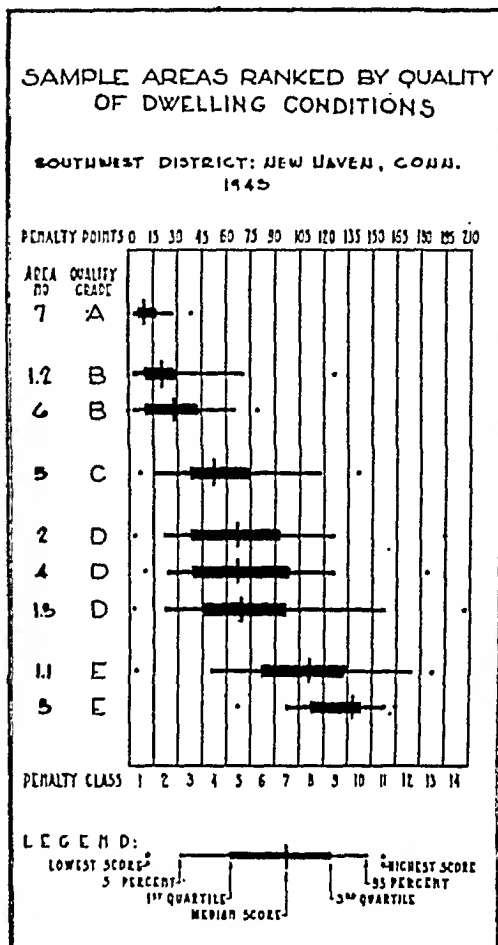

ried out jointly by a group of local agencies. This coöperative approach is well illustrated in the most recent demonstration survey, now being concluded in the Southwest District of New Haven, Conn.

This district takes in about one-fifth of the city's developed area and houses 42,000 of its 160,000 persons. It includes extreme slums, areas of problematic quality, and fringes of clearly self-sustaining neighborhoods. The health, building, and fire departments recognize the district as one of excessive inspection and enforcement burdens. The housing authority desires to find sites there for post-war housing projects. The city plan commission has undertaken a replanning study of the district, and wishes also to delimit clearance areas for enlargement of a terminal market and warehouse district. And the social agencies are wondering whether the housing future of the district will warrant investment in certain additional community center facilities.

In this area of diversified problems a joint appraisal has been sponsored and conducted by the committee and five governmental agencies: the local Health Department, City Plan Commission, and Housing Authority; the State Health Department; and the U.S. Public Health Service. The purpose of the study is to lay the groundwork for a coöordinated long-term program of housing enforcement, replanning and reconstruction for the district. Personnel or funds were supplied by each of the sponsors, and the work has been directed by the committee's staff. The interests of the several sponsors and their responsibilities have been set forth in a formal working agreement. It is thought by the partners in the undertaking that this "memorandum of understanding" may provide a pattern for a most fruitful type of joint attack on local housing problems.

After a preliminary screening study

FIGURE 1

of the 1940 Housing Census data, seven sample areas totaling 35 blocks were selected for appraisal.* These groups of blocks were chosen to represent the range from thoroughgoing slums to neighborhoods clearly free from serious housing problems. Fifty per cent of the 2,500 dwelling units in these blocks were inspected, and 30 of the blocks were completely surveyed for environmental characteristics. The accompanying figures give some highlights of the findings.

Figure 1 shows the quality of dwelling conditions (excluding environmental

* For purposes of analysis sample area 1 was later subdivided into three sub-areas (1.1, 1.2, 1.3), giving the nine areas of Figure 1.

characteristics) in the sample areas, and illustrates how the technic measures the range of over-all conditions from one area to another.

At the top of the figure is indicated the range of total penalty scores incurred by all dwelling units—from 0 to 208 points. This range is divided into penalty classes of 15 points each, as shown at the bottom of the chart. Units with total penalty scores of less than 15 points fall in penalty class 1; those with penalties of 140 points in class 10, and so on. The solid horizontal bar for each sample area represents the range of scores for 90 per cent of its dwelling units, and the scatter of 5 per cent of the cases at either end of the scale is shown by a terminal dot. The score of the median dwelling unit for each sample area is shown by a vertical bar; scores at the first and third quartiles are shown by breaks in width of the horizontal bar.

Thus, for example, the highest grade sample area (No. 7 at the top of the chart) shows a range of penalty scores from 0 to 38 points, but its median dwelling unit has a score of only 10 points. Fifty per cent of the units (from first to third quartile) show total penalties between 6 and 17 points; 90 per cent have scores between 2 and 28 points.

The chart reveals the relative quality of the sample areas at a glance. Two extremely poor areas show at the bottom of the figure; one quite good and two fairly good ones appear at the top, with four of distinctly worse quality between. These areas have been classified into five quality grades, from A to E (as given at the left of the chart), according to the penalty class and the number of basic deficiencies shown by the median dwelling unit for each area.

As a generalization for the present study, we may take the break between grades C and D as a rough dividing line between areas of more or less passable dwellings and those in which general corrective action by city departments will be needed. Over fifty per cent of the dwelling units in grade

D areas are substandard in the sense that they show one or more basic deficiencies as defined by the local sponsors. In the less bad of the two grade E areas, 94 per cent of the units have one or more basic deficiencies and 31 per cent show four or more. Further analysis indicates that grade E areas are clearly beyond acceptable rehabilitation of their present housing on any economic basis, and that housing of grade D is full of problems for the agencies charged with enforcement or rehousing.

Some of these problems are indicated in Figure 2. This gives the distribution of salient housing deficiencies, for the sample areas grouped by quality grade. Thus, while Figure 1 *measures* the range of the problem, Figure 2 *describes* the problem in various parts of the range. Here selected environmental factors have been included with the dwelling characteristics.

Although room crowding is not the chief difficulty of this district, a considerable problem of overcrowding abatement is indicated by items 21 and 22 of Figure 2. Areas of grades D and E show from 42 to 69 per cent of their dwelling units with physical defects which usually cannot be remedied without expensive or impracticable structural changes (items 8, 9, and 13). Over one-third show extreme disrepair (item 18), serious daylight obstruction by adjacent structures (item 5), and inadequate room sizes (item 15), the latter two at least being usually curable only by demolition. Separate analysis of D and E grade areas, of course, shows considerably higher deficiency rates in the latter than the figures given here.

Environmental characteristics shed additional light on the difficulty of rehabilitating such low-grade areas to meet contemporary housing standards. Fifty-eight per cent of the street frontages in grades D and E have a very

			Per cent of Blocks or Street Frontages Incurring Penalty Scores within the Qualifying Range		

*Per cent of Blocks or Street Frontages
Incurring Penalty Scores within
the Qualifying Range*

1. For most of the deficiencies the range of possible scores begins with 1 or 2 penalty points. In order to show here only the really significant defects, those dwellings or street frontages with slight penalties for any item have been excluded.
2. Space limitations preclude an accurate statement here of the criteria on which this item is scored. As noted in the text, all deficiencies are reported in terms of objective characteristics, not in such loosely descriptive terms as are necessary here. Scoring is done from precise rating tables.
3. Applicable only to tenements with public halls.

high concentration of industrial or commercial uses (item E5), typical of downtown slum districts. This problem is emphasized by the almost equally high percentage showing severe degrees of specific nuisances (E7) such as noise, vibration, conflagration hazard, odor,

and smoke associated with non-residential uses. Public playgrounds within normal walking distance (E22) are lacking for over two-thirds of the blocks in grades D and E. Crowding of the land by buildings (E1) is not so serious here as will be found in many slums,

but the prevalence of street hazards (E10) is the earmark of a district so cut up by traffic arteries as to be unsuitable for housing without replanning the traffic pattern.

Figures 3 and 4 give the characteristics of a typical dwelling in a grade E area. In Figure 4 is used the rating form prepared in the office for each dwelling unit, which shows the specific judgments for individual dwellings made possible by the technic, in addition to general evaluation of areas. The dwelling whose photograph and score are given here is the median case for Area 1.1, and is thus both better than half and worse than half of the others in this group of blocks. This dwelling unit is on the second floor rear of the building pictured. The three basic deficiencies of this unit and its structure are: lack of exterior or incombustible means of egress available to all dwelling units; disrepair of floors and plaster amounting to a definite safety hazard; and a family size which, in relation to both the number and substandard size of the rooms, causes excessive crowding. Additional defects include serious obstruction of daylight by neighboring structures, a bath tub rendered largely meaningless by lack of piped hot water, and stove heating for only two of the five rooms. It is clear that slum conditions are not restricted to the shared toilet, overcrowding, and the lack of repair which provided the grist for the hopper of old-line housing literature.

In these D and E grade areas, then, we have a sketch portrait of thorough-going slums, many of which should be cleared out as soon as possible, and which meanwhile call for correction orders and systematic reinspection. Even archaic law is clearly violated by many of the conditions brought to light. At least the eight blocks comprising the grade E areas of the present study are definite candidates for demolition, since they show considerably higher

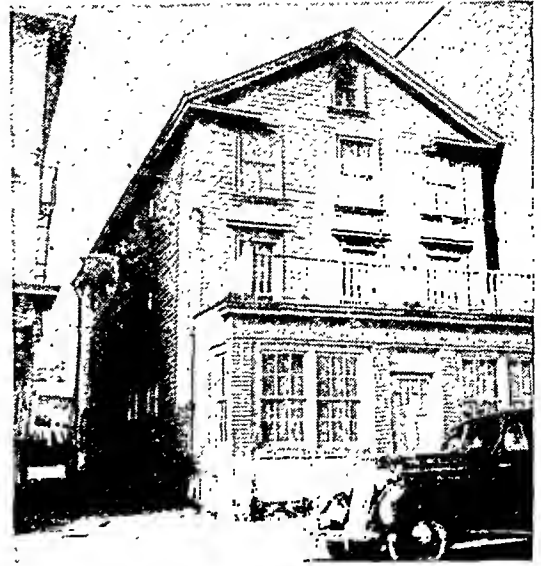

FIGURE 3—Typical Dwelling of a Grade E Area

penalty scores and a wider spread of basic deficiencies than a block in another part of the city which was cleared and rebuilt by the local housing authority because of the impossibility of rehabilitating it.

But what is the extent of these slums in the Southwest District as a whole? What proportion of the families live, for instance, under the conditions implied by grades D and E? How large are the areas which appear ripe for slum clearance? Where is drastic housing enforcement indicated? Where are the mild problem areas in which blight can perhaps be stopped and rehabilitation encouraged? The accompanying map (Figure 5) makes it possible to begin answering questions of this type, and these answers can be refined as necessary by further analysis of the appraisal data.

This map classifies all blocks in the Southwest District by quality grade of dwelling conditions as discussed above, with grades D-E and A-B combined for the sake of simplicity. The blocks of the sample areas are shown in heavy outline. For these the quality grades are definitive findings of the coöperative survey. The remaining areas have been

provisionally classified by scoring the 1940 Housing Census data for these blocks, using a rating scheme based on that of the committee's technic.

Under this scheme, the Census data for blocks of the sample areas were first compared with the survey findings; penalty scores were then assigned for the three most diagnostic items of the Census to give a

FIGURE 5

basis for computing presumptive quality grades. When the scoring formula had been refined so as to produce substantial agreement between the grading obtained from the Census data and the grading of the complete appraisal method, classification by presumptive quality grades was extended to the remaining blocks of the district. The map gives the result of this process, slightly generalized for legibility at a reduced scale. While the validity of such use of the Census data must be further tested in other cities before it can be recommended for general use, it is clear that for this section of New Haven this rapid method of projecting the survey findings is accurate for broad policy-making purposes. Projection of the environmental appraisal throughout the district by an index method would be desirable to refine the map, but since close agreement has been found in this particular section between the quality of dwellings and that of the environment, the present map can be taken as a reasonable approximation of the combined appraisal. This would definitely not be true in many other places.*

One large and several smaller concentrations of presumptive D and E grade housing appear as the core of the problem. These are connected by continuous belts of C grade blocks. The areas mapped as grades D and E account for 3,200 dwelling units, or 25 per cent of those in the Southwest District. Obviously not all dwellings in this group will warrant clearance or even drastic remedial action, but on the other hand a considerable number of the blocks provisionally classified from the Census data as grade C (accounting for another 28 per cent of the dwellings) can be expected to show marked concentra-

tions of grade D or E conditions when further analyzed. Therefore 3,000 families seems reasonable as a preliminary figure for the number of families in the district needing correction of their housing conditions by official action, whether this be mandatory improvement of existing dwellings or slum clearance and reconstruction.

The encroachment of grade C blocks into higher grade areas indicates a spreading of blight which local agencies will wish to check, both as a protection to the remaining unspoiled neighborhoods and as a safeguard to the city's tax base.

Local agencies are now planning to extend the appraisal throughout the city, with the purpose of delimiting all problem areas and of analyzing these areas as necessary with the committee's full appraisal technic.

When the appraisal is carried through successive stages in the normal process of the technic, special problems of enforcement and rehabilitation reveal themselves sharply. These will extend at least into C grade and often somewhat into B grade areas. In one survey area, when the findings were classified by tenement and non-tenement buildings, attention was focused on the need to extend legal controls beyond the old-line tenement law in force, for in some respects the conditions were worse in one- and two-family dwellings than in the larger structures. In another case the special need of Negroes for housing relief was clarified, for it was shown that in a district of mixed white and Negro occupancy the Negro houses were 35 to 150 per cent worse in every rental bracket than those occupied by whites, as measured by median penalty scores for physical facilities of the dwelling.

Does such an appraisal cost too much? Can man power be found for it in these days of personnel shortage? Data collection for the 1,280 dwelling

* This method of employing the Census findings to project a qualitative judgment throughout considerable areas has not yet been tested outside New Haven, but there it has shown very satisfactory results. It is hoped that further tests in other cities will justify the use of the committee's technic and the Census data in combination to obtain relatively rapid evaluations of an entire city as a guide to official policy. The importance of this possibility can hardly be overstressed, for the Census data are available block by block for all cities of over 50,000 population, and they offer, if translated into a screening measure of housing quality, an invaluable and most economical method for delimiting problem areas for further intensive study.

units in the Southwest District study was done with 4 man-months of inspectors' time. Office processing and primary analysis of the dwelling data required between 3 and 4 months' time of one clerk.*

This moderate amount of work is making it possible for the city authorities to arrive for the first time at a basic understanding of housing needs in a substantial portion of the city. It is worth remarking that had not the 4 man-months of field work been assigned to this productive purpose, they might well have been spent on relatively aimless investigation of nuisance complaints to the health department. A sanitary engineer in the group which viewed the first findings of this study exclaimed, "I would be glad to see my inspectors drop all work based on nuisance complaints for two years if necessary, to get this kind of rock-bottom information. On the basis of such material we can begin to plan for some kind of lasting remedy. We could go on for twenty years with ordinary inspection methods, and at the end of that time be exactly where we started."†

IMPLICATIONS FOR OFFICIAL HOUSING POLICY‡

The committee believes that the use of such an appraisal technic on any considerable scale will have effects of the first importance for public policy in housing and city planning. We believe, furthermore, that public health departments have a striking opportunity to promote among other city agencies the

idea of jointly measuring and interpreting the local housing problem, for purposes such as those discussed.**

Only by appraisals of some such type can neighborhoods be classified as to their fitness for continued housing use or their need for clearance and reconstruction. As another of our subcommittees has said, "We must begin to think of comprehensive housing programs in which systematic inspection and official designation of substandardness by areas will serve to guide the agencies of reconstruction into slum areas where improvement under the police power is hopeless, but which may offer prime opportunity for rehousing or other rehabilitation projects. In other words, the vigorous and imaginative exercise of regulative powers may supply for the first time a method of earmarking whole districts, helping to indicate both the relative urgency and the

† Throughout the development of the technic, the committee has stressed the need for simplicity in methods of gathering and analyzing the data, both in order to insure that routine personnel could be used (with a reasonable amount of skilled direction) and in order to minimize the amount of tabulation and analysis required to yield significant findings. The scoring system, for example, since it provides an index or summary expression of over-all housing quality, eliminates the need for certain refined tabulations and analyses ordinarily required with other technics. Scoring the schedules, which might be thought a cumbersome procedure, has been reduced to a rapid and purely mechanical office routine by designing the field schedules in relation to this scoring process. Finally, it may be pointed out that while very large-scale appraisals with this technic might well make use of machine punch-cards and electric card-sorting equipment for tabulations, we have designed our procedures around the simpler manual system of marginal punch-cards. This type of card is processed by a method of needle-sorting which can be quickly learned by any intelligent clerk; and there is almost no expense for equipment. In using these cards we have developed simple and extremely rapid methods of analysis by percentage scales. Use of these scales eliminates the need for manual counting of the sorted cards—which need has usually been regarded as the basic limitation of the marginal punch-card system.

‡ For a fuller discussion of the applications of the technic see section IV of *Public Health Reports, Reprint No. 2359*, previously cited.²

** A manual of the complete procedures for this appraisal technic is being prepared, in order to make the method available for general use. The committee welcomes inquiries from local agencies which might be interested in using the technic.

* These figures exclude time of the committee staff, divided between supervision of other personnel and developmental work on the procedures. They exclude also time required for the environmental appraisal. No comparable figure can yet be given for this part of the technic, since it was carried out complete for the first time in the Southwest District, being conducted in part with experimental procedures. The experience of the study, however, has pointed the way to simplifications in the environmental appraisal which should result in comparable economy with this part of the technic.

types of constructive programs needed for improvement or rebuilding."³

Specifically, this type of appraisal will help in directing enforcement toward the kinds of control most needed in a given area or for different types of housing. It can supply part of the basis for redrafting obsolete ordinances or statutes to meet the urgent housing problem of the community. It can be used during the war to disclose marginal dwelling structures with unused capacity and worthy of reconditioning to meet the emergency demand. Its findings should be of major value, when appropriately presented to the general public, in rallying popular support for needed housing appropriations or legislation.

Finally, and perhaps most important, surveys of this type, conducted rou-

tinely in problem areas by the regular personnel of collaborating city departments, will supply answers to many of the policy and technical questions involved in housing and rehabilitation schemes for the post-war period. If a large and well planned housing program is to be an actuality in our democratic peace, there is much groundwork to be laid at once.

NEWSPAPER SUPPORT, SOUTHERN STYLE

On April 14, the health officers of 33 cities and counties in 18 states were notified by wire that their communities had won awards in the 1942 National Health Honor Roll, annual contest in community health promotion and protection sponsored by the Association and the U. S. Chamber of Commerce. Washington County, Miss., was one so honored. Dr. J. P. Ward is the Director of the Health Department.

On April 30, the Greenville, Miss., *Delta Democrat-Times*, a daily with a circulation of 6,000, nearly all in Washington County, issued a 12 page tabloid supplement devoted entirely to health. Banner headlines announced the winning of the coveted award; a three column cut of the Health Department personnel adorned page one; the history of the department was detailed, and the story of the National Health Honor Roll told with completeness and accuracy. Local advertisers used full and half page space, in many instances, to congratulate Dr. Ward and his staff. Pictures of various health department activities were featured and each received mention and credit in an individual headlined story. One article candidly emphasized in a 20' caption that the "TB Program Is County's Weakest."

If the citizens of Washington County do not know now what they pay some of their taxes for, and are not satisfied that they are making a good investment,

it is not the fault of the *Delta Democrat-Times* nor of Dr. Ward and his colleagues.

COÖPERATIVE SYPHILIS STUDY IN CLEVELAND

The Joint Social Hygiene Committee of the Academy of Medicine in Cleveland and the Cleveland Health Council has published an informative study of the cases of syphilis under treatment in Cuyahoga County, Ohio, in March, 1942, comparable to studies made each March since 1938. Through the coöperation of 1,516 practising physicians and the directors of hospital out-patient departments, hospitals, and institutions, it was found that cases of syphilis under treatment by private physicians and in hospital out-patient departments, hospitals, and institutions, after decreasing each March from 1938 to 1941, increased in the year ending March, 1942. Infectious cases of syphilis increased from 537 in March, 1941, to 641 in March, 1942.

Dr. James A. Doull, Chairman of the Joint Social Hygiene Committee, points out that a rise in the number of patients treated does not necessarily mean higher incidence of the disease but may be indicative only of greater activity in case finding.

The report is a first rate example of a pattern for problem solving at the level of the local community, where resources are mobilized for a well planned effort against an important menace.

SOURCE MATERIAL FOR TEACHING HYGIENE

Those who attended a session of the

Laboratory Section of the A.P.H.A. at the St. Louis Annual Meeting in October, 1942, will recall a scholarly paper by Colonel Edgar Erskine Hume, M.C., U. S. Army, on the Contributions of the Medical Corps of the Army to the Public Health Laboratory. This manuscript has been published in *Science* for April 2, pages 293-300, and should be useful to those who seek fresh sources of material keyed to the present-day emphasis on military medicine for teaching purposes.

WELCOME TO VOL. 1, NO. 1, ESTADISTICA

The first issue of *Estadistica*, Journal of the Inter American Statistical Institute, has just come through. Halbert L. Dunn, Director of the Census, is Secretary General of the Institute, and Juan De D. Bojorquez is Director and Editor-in-Chief of the Journal. The purpose of the official Journal of the Institute is stated to be that of the Institute itself "to advance statistical science and administration in the nations of the Western Hemisphere and to further the practical use of statistics in the solution of social and economic problems which are common to these nations."

The magazine is published in Mexico City and will be issued quarterly. The first number is dated March, 1943. It is printed in clear, open-faced type, is pleasant to look at and to handle. The twenty-odd major and short articles occupy 191 pages. At least half are in English with summaries in French, Spanish, and Portuguese. The others are summarized in English. The lead article, which describes the structure and program of the Inter American Statistical Institute, appears in full in Portuguese, English, and Spanish, with a summary in French.

There is no emphasis on vital statistics in this issue, beyond a discussion of the 5th Census of Brazil, indicating by inference some of the problems facing

the public health worker in that country, but the Conference has a Committee on Demographic Statistics to which a number of projects have been assigned and upon which reports may later be expected. The projects have to do with the addition of an alphabetical index, in Spanish and Portuguese, to the *International List of Causes of Death*; the development of standards for collecting and compiling vital statistics and the establishment of a model center as part of a vital statistics system; establishment of a uniform system for the maintenance of current health statistics and hospital statistics and the cultural classification of Indians in the population census.

The subscription price of *Estadistica* is \$2.00 per year and subscriptions may be placed with Dr. Halbert L. Dunn, Inter American Statistical Institute, Bureau of the Census, Washington, D. C.

VISITORS FROM ABROAD

Every now and then, and more frequently this year than last, one of the staff comments, "There must be a lot of boats in. See these letters and magazines from England, from Russia and from Switzerland."

These safe arrivals, after long and hazardous journeyings, are heartening in many ways. They tell us mutely that progress is being made in the war against the U-boat. They assure us that the lamps have not gone out all over Europe. They give testimony to the courage and fortitude of public health workers overseas, who, under the most difficult circumstances, work, write, and see things through the press.

The English medical and health journals are no longer months late. That they could be published at all remains a miracle.

The League of Red Cross Societies continues to distribute mimeographed material from its office in Geneva.

Publication No. 5, 1942 series, recently received, contains articles on "The Nurse in Industry," "Mental Hygiene," and one on the vitamin C content of Swedish briar rose hips. The cultivation of briar rose hips may have significance for the United States, if, as is claimed, they are superior to oranges as a source of vitamin C and, further, that they may be brewed to provide a "most excellent beverage, far healthier than either coffee or tea."

The U.S.S.R. Society for Cultural Relations with Foreign Countries has been responsible for the appearance in this country of many interesting documents. Late arrivals include copies of general magazines, pamphlets on various aspects of Russian life, and an impressive volume on Pushkin—all published in Moscow and in English. If you have a periodical to exchange for publications of the Society, it would be worth while to suggest the arrangement. The address is: B. Gruzinskaya 17, Moscow 56, U.S.S.R.

THE HIGH SCHOOL VICTORY CORPS

High School Victory Corps are being established in many schools throughout the country. Coöperative efforts of the U. S. Office of Education, the Army, and the Navy have launched this national effort to secure the active participation of high school youth in the community's war work, and to train youth for war services which are ahead when school days are over.

Building and maintaining physical fitness is an important part of the program. Two manuals prepared by the Office of Education in coöperation with the Army, the Navy, the U. S. Public Health Service, the Office of Defense Health and Welfare (now called the Office of Community War Services), and other agencies offer detailed suggestions to schools in developing physical fitness programs. They are entitled *Physical Fitness through Physical Edu-*

cation for the Victory Corps and *Physical Fitness through Health Education for the Victory Corps*.

In reprinting the advance digest of the second manual in *Health Briefs*, Tennessee Department of Public Health monthly, the Editor, Dr. Robert H. White, remarks in a footnote:

Although this article is worded for high schools organized in the Victory Corps program, the potential application is much wider. The proposed health measures include the same fundamentals that every school should be giving balanced emphasis to, regardless of secondary or elementary level, whether inside or outside of the "Victory Corps" framework.

A FOOTNOTE TO THE PHYSICAL FITNESS PROGRAM

Dr. Carl A. Wilzbach, Health Commissioner of Cincinnati, under whose direction school health services are conducted, writes of recent experiences in his city. We quote:

When the physical fitness program was started we had a meeting with the Superintendent of Schools, and decided that there would be no physical fitness efforts made until we had again examined senior high school boys and girls to be sure that they could undergo vigorous training.

The examinations have been completed in the public schools and we are at the present time taking the parochial schools. Some 2,000 boys and girls were examined in the public schools, and I want to mention only a few things which we found. We set up a scheme to take care of the physical defects which we found in advance. These included the private physicians, and dentists, the community facilities including the public health clinics and out-patient dispensaries. We found that 1,552 had defective teeth, 335 weak and flat feet, 153 with vision defects, 100 with hearing losses, 131 with heart and cardiovascular system abnormalities. Public health nurses are now following all of these children discovered to see that their physical defects are cared for. We were surprised to find how many could go to private physicians and this, of course, made the clinic and public health load much less.

I think there is no doubt of the importance of this effort because these boys will soon be called before selective service boards and

the girls will either be in some branch of the armed forces or in industry.

ADVENTURES OF A MEDICAL OFFICER IN THE PARACHUTE INFANTRY

Captain John Y. Battenfield, Surgeon, Army Medical Corps, illuminates one aspect of army medical life in some recent letters. Dr. Battenfield, before he was commissioned, was connected with the National Society for the Prevention of Blindness, New York. He received the M.P.H. degree from Johns Hopkins in 1942.

Here are excerpts from two letters written six weeks apart:

"You may be interested to know that I went from Sheppard Field to the Medical Field Service School at Carlisle Barracks and from there to the Parachute School at Fort Benning where I qualified as a parachutist on December 5 and very shortly thereafter was ordered to foreign service. At present I am a Surgeon in the Parachute Infantry and am enjoying my work very much. All our medical enlisted men and the medical officers jump with the troops both in training and in combat.

"We have had several very interesting jumps since we have been here. On one we got about 200 men into the jungles, including ourselves, due to an erroneous weather report on wind velocity. I was the second officer on the ground, or rather in the trees, and it certainly was quite exciting to watch the remainder of the 200 land in the trees. Not a man was seriously injured.

"My Commanding Officer has requested that I prepare a pamphlet for the men on jungle health. In order to understand the problems concerned better than I could by consulting the literature only, I took 15 men, including myself and another officer, to act as guide for an 8 day jungle hike. Believe me, it was certainly educational. I have never seen so much rain and mud. We walked up and down mountains of rocks and mud, waded rivers, slept in wet, cold hammocks, were bitten by mosquitoes, chiggers, ticks, ants, and buffalo gnats. We ate jungle rations which are excellent, and C rations which are very heavy to carry and very unpalatable. We were resupplied by transport plane and parachute packages. We had only two cases of dysentery during the trip. Our water was of course chlorinated. Prac-

tically the entire contents of first aid kits were thrown away after the second day because of the weight, as well as everything else not absolutely essential. All in all it was very interesting but not something one wishes to repeat very often."

"Since my last letter we have been extremely busy and have had a number of unusual problems. Your letter has remained unanswered so long because shortly after its arrival we had a night jump with the task of capturing one of the large airports here (just a training problem) and I was number 21 man and last in my stick of jumpers. By the time I made my exit from the door of the plane we had overshot the jump field and I made a very hard landing against a steep hill about 200 feet high. The night was so black it looked perfectly level and I did not expect such a terrific jar. The result was that I fractured my right foot and suffered a mild cerebral concussion. The joke of the situation was that I had the Surgeon of this area as a guest inspecting our evacuation facilities under difficult circumstances and I was the first casualty. We lost 10 per cent of our command as jump casualties because of the darkness and a high wind, but captured the airport completely."

DESK BLOTTERS PROMOTE HEALTH EDUCATION OF DOCTORS

The Bureau of Social Hygiene of the New York City Department of Health, of which Dr. Theodore Rosenthal is Director, has recently distributed an informative blotter to doctors which carries the following information.

Sulfathiazole is the accepted drug for the treatment of gonococcal infections.

Sulfathiazole may be administered on either a 5-day or a 10-day plan. The 5-day plan is preferred, provided there are no indications for the longer course. The total amount of the drug is prescribed at the first visit, but the patient should be seen every 48 hours.

FIVE-DAY PLAN: Administer 1 gram (15 grains) of sulfathiazole 4 times daily, after each meal and at bedtime, for 5 days (total dosage 20 grams).

TEN-DAY PLAN: Administer $\frac{1}{2}$ gram ($7\frac{1}{2}$ grains) of sulfathiazole 4 times daily, after each meal and at bedtime for 10 days (total dosage 20 grams). No local treatment of any type is necessary.

If the patient is not cured with the first course of treatment, stop sulfathiazole for

one week and then repeat the course of sulfathiazole as before. In the interim, local therapy with mild antiseptics should be given.

In women, acute gonococcal salpingitis requires treatment in bed. Two grams of sulfathiazole per day as prescribed in a suggested form of oral treatment. Fever, pain and tenderness almost or entirely disappear in from 48 to 96 hours in most cases. Pelvic or Bartholin gland abscesses must always be treated surgically.

Consultation is desirable in the presence of complications or failure to react promptly and favorably. Routine serologic examination for syphilis on all patients is recommended.

SPRING TONIC (PRINTED)

As cheerful as a dandelion and with the same high visibility among a host of less imaginative materials on the subject is a nutrition leaflet entitled "For Health" for which the Mississippi State Board of Health, Felix J. Underwood, M.D., Executive Officer, is responsible. Dandelion-yellow, garlanded with fruit jars and vegetables, and with casual hand-lettered vegetable-stand signs on its front cover, it makes one hungry for a tomato and lettuce sandwich and a glass of fruit juice. What more than that can a leaflet on fruits and vegetables do?

REPORT OF THE NRPB

The alacrity with which the Report of the National Resources Planning Board was dropped from the newspapers has been equalled only by the short shrift given two years ago by the press generally to the findings of the Temporary National Economic Committee. That the newspapers of the country failed to follow through with the implications to the public for a happier, more secure post-war world, set in perspective by the recommendations of the NRPB, is obvious by the results of a recent Gallup poll. Indeed, it is obvious that the original and, in most instances, the only notice taken by the nation's press of this significant study was totally inadequate. The

Gallup poll indicated that the public is uninformed and therefore unimpressed. Seventy-five per cent of the persons queried knew nothing about the report. Thomas Jefferson said if he had to choose between good government and good newspapers, he would select the latter. Where are the good newspapers of the country on the issue of social security?

New York's daily, *PM*, has done the exceptional job with the report of the NRPB. It has not only followed through, but it has skillfully related many of the individual recommendations to a present Army sergeant and his family, translating the technical language to the language of the man in the street, in this case, an ex-railway employee, who expects to return to his \$30 a week position when the war is over. There is no generalization; instead, each recommendation is projected into the man's life in terms of him, his wife, his child, and his pocketbook. This is finding him where he lives. This is interpretation of a high order, recommended to public health workers as a technic.

RELATIVE CONTRIBUTIONS OF PROTEIN RICH FOODS

A new and vivid method of visualizing the contributions to the dietary of protein rich foods has been published by the Division of Maternal and Child Health of the Oregon State Department of Health, of which Mrs. Laura P. Wells is consultant in nutrition. Using circles to represent the daily requirement of a specific nutrient, the contribution of a given portion of various protein rich foods is indicated graphically in such a form that it could be used in the average family kitchen. The chart is colorful and commendable in that it does not complicate the picture by an exhaustive treatment.

The chart was compiled by Dr. Margaret L. Fincke, Associate Professor of

Foods and Nutrition in the Oregon State College, and has been published jointly by the State Board of Health and the Oregon Nutrition Council. The charts are obtainable in quantity lots at a cost of \$1.25 per 100.

THE HOUSING AUTHORITY AND THE HEALTH DEPARTMENT

The relation of the health officer to the slum clearance and low rent housing movement is not as close here as it is in England; yet nevertheless even in this country there are numerous and important points of contact. A survey of a group of recent housing authority reports prepared for the *Journal* by C.-E. A. Winslow, Dr.P.H., Professor of Public Health at Yale University, brings out some of these relationships.

The importance of housing to the health department is indicated by statistics in the report of the Boston Housing Authority, showing that on the slum sites replaced by eight projects of the Housing Authority, 21 per cent of the original dwellings had no water-closet within the dwelling unit, 62 per cent had no tub or shower, 47 per cent had no supply of hot water, and 93 per cent had no central heating. It is clearly desirable that the health officer should have a clear idea of the distribution of such substandard housing in his area. Memphis, Tenn., has played a pioneer rôle in obtaining such information, partly, no doubt, because Dr. L. M. Graves, City Health Officer, is also a member of the Housing Authority; this Authority in its last annual report refers to a study of the whole area within a five mile county radius, revealing the fact that 62 per cent of the dwellings in that area are substandard. Baltimore, Md., is another city which has made notable contributions in this field, and Dr. Huntington Williams's last report as health officer notes the approval of two new ordinances giving the

Commissioner of Health broad powers in dealing with unhygienic housing and the increase in housing inspection made possible by an increased field staff.

In many communities, voluntary associations coöperate with both the health officer and the Housing Authority. Thus the Pittsburgh Housing Association reports continuing intensive surveys of the city section by section which should prove invaluable in constructive planning. The Washington Housing Association has done an admirable piece of work in preparing a comprehensive housing code effectively coördinated with projected revisions of local building and health codes. It also reports on a comprehensive study of the rodent problem, which is leading to a city-wide campaign under a sanitary engineer employed by the Health Department.

Many housing authority reports refer to the development of clinics and health centers in the projects themselves—another type of coöperation of substantial significance. The Los Angeles Authority reports that "young America must be kept healthy—so the Los Angeles Health Department sees to it that youngsters are kept germ-free in its well-baby conferences, held at various locations throughout the city including public housing developments." The report of the New York City Housing Authority notes that "the Child Health Stations at East River Houses and Kingsborough Houses were designed with a new type of room arrangement to permit greater privacy to the patient, more quiet for the staff, and less congestion for all. The Authority enlisted the coöperation of the Department of Health in making these design changes. The combined study by the two agencies resulted in sound improvements apparent in the plan for the proposed Child Health Station for Amsterdam Houses."

The Pittsburgh Housing Association report says: "Much of the Associa-

tion's program is devoted to direct coöperation with other social agencies, such as the Public Health Nursing Association . . . The Public Health Nursing Association, always aware of problems of sanitation and safety in the home, reported 52 per cent of the housing complaints received in the last year." As to results achieved, the Peoria Housing Authority cites the following comments by tenants: "The first winter in several years I have been able to walk" (from an arthritic). "The steady heat and warmth have done my joints more good than all the doctors and their medicine" (from an elderly woman with rheumatism). "We have not had a single cold all winter." "All my three children had pneumonia last winter because the house was so old and cold; this winter they have not had a slight cold."

More authoritative to the readers of the *Journal* is the following comment by Dr. J. I. Linde, Health Officer of New Haven, in the Report of the New Haven Housing Authority. He says:

"Of all city officials, the health officer, by virtue of his official duties, is in the best position to sense the connection between housing and health. Historically, housing laws (tenement house acts), together with those concerned with the control of contagion and the laws of hygiene, have formed the basis of the Sanitary Code.

"The three low rent government housing projects have been quick to demonstrate the positive effects upon healthful living which good housing offers.

"Demolition of entire blocks of slums has eliminated housing complaints from these areas to the Health Department, so that the health inspector's functions in such areas are reduced to that of health educator. No overcrowding, sanitary plumbing, adequate heat,

light, ventilation, numerous safety features—all of these have exerted a direct influence upon the physical side of the occupants' lives by serving to keep the incidence of disease and accidents to a minimum.

"Provision of adequate play space for children, nursery care of children of working mothers, recreational facilities and educational programs for adults, construction of homes to suit occupants' needs and comfort, and planning throughout the homes for the healthful living of the occupants—these have contributed immeasurably to the psychological factors in health which make for balanced mental hygiene for the individual and sound family and community life of groups.

"Finally, establishment of health centers in the housing projects to carry on health programs (such as dental care, prenatal instruction and care, infant hygiene, health education classes, etc.), is bringing necessary health services closer to the citizens of New Haven.

"Thus, the housing project is becoming the generator of healthful living, immediately influencing the lives of its residents as well as those in the surrounding areas."

In his participation in the housing movement, the health officer can obtain substantial aid from our Committee on the Hygiene of Housing. This committee has recently prepared an appraisal procedure for the measurement of the quality of individual dwellings and environmental areas which is far superior to any hitherto available and yet so simple that it can be applied by the average health department inspector. The committee is also making studies of the principles underlying the legal control of housing, particularly through the application of sanitary codes, which should prove of substantial value.*

* Information in regard to the work of the committee may be obtained from its headquarters, 310 Cedar Street, New Haven, Conn.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Osler's Principles and Practice of Medicine—Originally Written by Sir William Osler. Designed for the Use of Practitioners and Students of Medicine—By Henry A. Christian. (14 ed.) New York: Appleton-Century, 1942. 1,500 pp. Price, \$9.50.

For the past fifty years Osler's *Principles and Practice of Medicine* has been one of the outstanding medical textbooks in the English language. The 14th edition revised by Dr. Henry A. Christian maintains the tradition of Osler's original volume in that it is written entirely by a single author. The comprehensive manner in which disease is treated in this newest volume is a tribute to Dr. Christian's breadth of interest and experience in internal medicine.

The question may be debated as to whether a single individual is justified in undertaking the tremendous task of revising or writing a textbook of medicine in this age of rapid advance in medical knowledge. Vast as the subject of medicine was in 1892, its essence was contained in Osler's original volume, which he compiled almost single handed. Medicine then, however, was largely a descriptive science. Much was known about the clinical manifestations of disease and its morbid anatomy, but of etiology, pathogenesis, and specific therapy there was but fragmentary knowledge. Today the author's task is far more difficult. The premedical sciences in particular have added a prodigious body of facts not known to the physician of the last century. No longer can all of medicine be mastered by a single mind. The day has come when a textbook of

medicine cannot be sufficiently comprehensive unless compiled by a series of contributors, each of whom is qualified as an expert in a specific field of medical science. Although Osler's *Principles and Practice of Medicine* will continue to be widely used by American students of medicine, it is doubtful if it will remain among the leading textbooks in the English language if subsequent revisions are made by a single author.

W. BARRY WOOD

Fundamentals of Immunology—By William C. Boyd, Ph.D. New York: Interscience Publishers, Inc., 1943. 446 pp. Price, \$5.50.

The primary value of this book is its extensive modern discussion of antibody-antigen reactions and the considerations of the various theses involved. The author states that the point of view adopted has been, so far as possible, the point of view of the chemist, and it would appear that this is a very true statement of the approach. The book scarcely deals with specific problems of infection and for that reason has little of applied value to the clinician or the diagnostic laboratory worker. However, for the individual who is seeking a background of current investigation in terms of physical chemistry, there is much to be gained; in fact, the book is so weighted in this direction that many of the other sections seem to be included only for the sake of completeness in headings. It is quite clear that the author deliberately avoids discussion of mechanisms of infection and immunity except as serological reactions. The final chapter, dealing with laboratory

and clinical technic, would serve well in outlining a course to illustrate the various immunological procedures.

There has been need for a book attempting, in a descriptive manner, to make the basic reactions of immunology clear in terms of modern concepts without losing the student in a mass of symbols. This effect has been gained.

THOMAS FRANCIS, JR.

Orthopedic Conditions at Birth—Nursing Responsibilities—*By Jessie L. Stevenson, R.N. New York: Joint Orthopedic Nursing Advisory Service of the National Organization for Public Health Nursing and the National League of Nursing Education, 1943. 80 pp.*

Nurses as professional workers are becoming increasingly aware of the orthopedic content of everyday nursing care, and the need for the interpretation of orthopedics in terms applicable to the responsibilities of the nurse caring for the infant, supervising the health needs of the preschool or school age child, or providing nursing care for the individual confined to bed for a long period of time because of some infectious process. This handbook, *Orthopedic Conditions at Birth—Nursing Responsibilities*, will be welcomed by those nurses who are interested in the interpretation of orthopedic care as it relates to the care of the infant and young child.

A general review of anatomy, etiology, and pathology is presented for each of the several conditions discussed. Present trends in treatment are briefly reviewed. The discussion is directed toward the nursing responsibility for recognition of these conditions and prompt reporting of observations to medical authority in order that diagnosis may be made and early care instituted. Considerable emphasis is placed on the responsibility of the nurse in giving interpretation and support to

the family during a prolonged treatment period, and in promoting desirable family and community attitudes toward conditions which cannot be totally corrected.

The material presented in this handbook, together with the references cited, constitute a means of rapid review for those familiar with these conditions and a means of developing a more extensive fund of information for those less familiar with the conditions cited. It should prove of particular value to both institutional and public health nurses engaged in any phase of child and maternal care.

FLORENCE PHENIX

A Surgeon's Fight to Rebuild Men (An Autobiography)—*By Fred H. Albee. New York: Dutton, 1943. 349 pp. Price, \$3.50.*

The publisher characterizes the author as "the world's foremost Ambassador in White," even though the title indicates that the book concerns something so undiplomatic as a "Fight." But before one has progressed far beyond Part One it is obvious that the title does fit the book, and after reading Chapter XXIV, which describes Dr. Albee's controversy with the New York County Medical Society, this reviewer was sure this theme had destroyed any possible effectiveness of the book.

Dr. Albee describes his bone graft surgery simply and well, both in the body of the book and in the appendix. That he is a master in this field is universally acknowledged, but one wishes he had admitted a few mistakes instead of tacitly corroborating Lowell Thomas's statement in the foreword that he is "one of the great surgeons of all time." The apparent purpose of the introduction into the book of several testimonial letters from former patients is to support this thesis.

The book lacks continuity, even

though there is a disingenuous attempt to show that his career as a bone graft surgeon was largely determined by observing his grandfather graft apple trees. The style is jerky, due to the author's tendency frequently to go rather far afield. In thus doing, he makes numerous loose, inaccurate statements, such as that Richard Strong "abolished" typhus in Serbia, that army medical officers at Hoboken were "compelled to deflu embarking troops," that the author's research in U. S. General Hospital No. 3 at Colouia, N. J., was "probably the only animal research performed in any army hospital in this country during the First World War." The author's statements concerning his status and activities at General Hospital No. 3 include numerous inaccuracies as well as several figments of a fertile imagination—this on the authority of his commanding officer, Col. Upshur, to whom Dr. Albee gives no credit for organization or administration. Dr. Albee's statement that he himself organized the hospital is overdrawn, to say the least, for he had no authority or responsibility at that hospital beyond that of any chief of a surgical service.

Much space is devoted to the Carrel-Dakin treatment, leaving the reader with the impression that this is still the preferred treatment, while only seven lines are devoted to the Orr technic, which is one of several technics which have practically superseded the Carrel-Dakin method. EDWARD G. HUBER

Food Poisoning—By G. M. Dock, Ph.D., M.D. Chicago: University of Chicago, 1943. 138 pp. Price, \$2.00.

A colleague of the late E. O. Jordan, student of F. W. Turner and an authority on food poisoning, Dr. Dock has had this book published at an opportune time. The individual concern about our food; the necessity for feeding large numbers of groups in war

production plants, naval and military areas, and the exodus of food handling personnel to more lucrative employment justify its being read and studied and kept as a reference manual.

Besides the introductory chapter, botulism, the Staphylococci, the Salmonella, the little known alpha-type Streptococci, poisonous chemicals and poisonous plants and animals are covered. Botulism and the Staphylococci are included, rightfully, in one-half of the book. The interest in and encouragement of home canning and the many outbreaks due to the Staphylococci justify this.

Although not replete with references, it is refreshing to observe that 90 per cent of the references cited are from publications of the past twenty years rather than those of the era when "ptomain" was the only cause of food poisoning.

Preventive means are given for practically every known type of food poisoning. Tables for use by the statistician, bacteriologist, and investigator are given, as well as suggested forms for questionnaires that may be used by the public health worker.

This book should be in the hands of every dietitian, army and navy mess officer, health department food control and laboratory personnel, as well as in hospital and other institution libraries. It should be consulted frequently before and during any investigation of food poisoning outbreaks.

FERDINAND A. KORFF

Plumbing Practice and Design, Volume 1—By Svend Plum. New York: Wiley, 1943. 308 pp. Price, \$4.50.

This book is an attempt to consolidate the scattered data on plumbing, to present these data in uniform terminology and in a manner usable for solving the many problems occurring in the design of plumbing systems. The

material is set forth and its use is left to the ingenuity of the reader, depending upon his knowledge of the underlying principles.

First there is a discussion of the types and causes of corrosion and how different materials react to corrosion. The remainder of the book in format resembles a set of specifications since recommended standards for all materials, piping, fittings, controls, accessories, pumps, etc., are included. Fire protection codes and regulations are included as well as a chapter on air piping and equipment.

The writer is to be commended in using only recognized accepted standards and specifications sanctioned by the federal government and the various technical societies, such as the American Society of Testing Materials, American Society of Mechanical Engineering, American Water Works Association, National Board of Fire Underwriters, New England Water Works Association, and for his frequent references to ASA Standards.

C. P. STRAUB

Intensive Rural Hygiene Work in the Netherlands East Indies—

By J. L. Hydrick, M.D. *Introduction by Professor J. Snapper. New York: The Netherlands Information Bureau (10 Rockefeller Plaza), New York, N. Y. Bull. No. 7, 1942. 83 pp.*

Dr. Hydrick has presented, in this pamphlet, in an objective and practical manner, the development and functions of a general public health program in the Netherlands East Indies.

He found from his work in Java that success depended upon a complete separation, administratively, of the program in community hygiene from the medical care program. In the United States, the trend has been to coordinate all community-wide activities in the promotion of health. Some health administrators believe that the medical

care program should be incorporated in the activities of health education.

Dr. Hydrick is convincing in his arguments that these two activities should be completely separated. He first discusses in some detail the principles of good public health education, and then shows in a realistic way the application of these principles to people in rural areas where superstition is common, and where approximately 65 per cent are illiterate.

The fundamental plan on which he developed his work is that any worthwhile and permanent public health program must of necessity win the active cooperation of the people. Furthermore, it must stimulate people to activity and to the practice of good habits of personal hygiene.

He found that the most successful means to accomplish this objective was through home visits and personal instruction. At the outset, trained nurses were used for this educational work, but they were found "to remain on a far too high level for the work." He then devised a plan in which hygiene teachers (*hygiene-mantris*) were used in home instruction in hygiene with considerable success. *Hygiene-mantris* are men who are carefully chosen on the basis of their personal qualifications. They are given an 18 months' course in hygiene before they are sent into the field. Their work is entirely educational. This plan succeeded where all other plans had failed.

He also found another individual to be valuable in village education: this was the trained midwife, who is sent into the villages to train the unskilled and untrained midwife (*doekoen-beranak*) in the elements of maternal and child health protection.

Dr. Hydrick emphasizes the fact that physicians were of little value to him in his health education work. He insists that medical personnel need special training before engaging in public

health, and believes that in the future the training of physicians in hygiene and protective medicine should be begun in the medical school. Plans were made for this training with the coöperation of the Public Health Service, in the Medical School at Batavia.

This pamphlet is a report of the Netherlands East Indies Health Service, first published in Dutch in 1937. The English translation may be obtained from the Netherlands Information Bureau, 10 Rockefeller Plaza, New York, N. Y. It is worthy of careful reading by all public health workers who are especially interested in rural health education. W. G. SMILLIE

Man in Structure and Function (2 Volumes)—By Fritz Kahn, M.D. Translated from the German and edited by George Rosen, M.D. New York: Knopf, 1943. 742 pp. Price, \$10.00.

Fritz Kahn's work, *Man in Structure and Function*, is an extraordinary production. It is distinguished in two respects: its illustrations and its statistical or numerical versions of anatomical and physiological data. The first is by far the more noteworthy. Dr. Kahn has the rare gift of visualizing his data, and he reveals a superb skill in projecting his visions in the form of three-dimensional, dynamic drawings. He has also a keen aptness in literally drawing analogies, and these serve to make abstruse relationships and functions easy to grasp.

The work, consisting of 742 pages of text and 470 illustrations, systematically surveys the entire body both anatomically and physiologically. Interspersed in the text are numerous references to pathogenic agents and conditions, showing the mechanisms by which these produce disorders in the human body.

Man in Structure and Function should prove particularly useful to health educators, biology teachers, and

nurses. But it is bound to be of interest to everyone who is concerned with the constitution and operations of the human organism. The translator, Dr. George Rosen, has rendered the text of the work, originally published in German, in clear and facile English. The publisher, too, deserves commendation for having produced a very handsome twin book.

There is, however, one observation that must be made concerning the text of the work and its illustrations. Both are at times too definitive and too categorical in substance and in implication. Those are the inevitable handicaps of simplification. Yet, without some simplification none but the expert could understand the human body in structure and function. With this minor reservation, Dr. Kahn's work can be welcomed as a valuable contribution to popular medical literature.

IAGO GALDSTON

The Infectious Diseases of Domestic Animals—By William Arthur Hagan. Ithaca, N. Y.: Comstock Publishing Co., Inc., 1943. 665 pp. Price, \$6.00.

The author's preface rightly describes this book which is an outgrowth of his lectures on "pathogenic bacteriology and immunology" at the New York State Veterinary College. It is not a textbook on bacteriology, as much of the material usual in such books has been omitted, it being taken for granted that the general principles of the subject have already been learned by the reader. On the other hand, it contains an unusual amount of material on the fungi, protozoa, and viruses pathogenic for domestic animals. The author states that it will be used by himself in his teaching and hopes it will be found useful to others giving similar courses.

The text is well and interestingly written. In describing the diseases due

to bacteria, enough of the cultural characteristics and methods of isolation of disease-producing organisms is given to make the subject clear. The discussion of diseases which are common to man and animals, or those which are transmitted from animals to man, is well done and sufficient.

The giving of proper credit for work is not as exact or complete as it should be. The reviewer believes in the historical method of teaching and is especially concerned in giving Americans credit for their work. For example, mallein was first made by the late Dr. Leonard Pearson, though usually credited to Kalning, a Russian. In a book by a veterinarian and intended for veterinarians, this seems an unfortunate omission, especially in view of the tendency of European writers to ignore American work—a tendency which has been to a certain extent now overcome. The author perpetuates the error of giving 1898 as the date of Theobald Smith's differentiation between human and bovine tubercle bacilli. It is true this date is correct for one of Dr. Smith's papers, but the first on the subject appeared in 1896.

The illustrations are on the whole good and abundant enough. On page 37, the picture showing the bleeding of horses for the production of anti-toxin is not in accord with general practice, and the legend misleading.

The book can be highly recommended as covering the ground outlined in the Preface. We wish that human physicians could be induced to read books of this sort. Even to those who have already done a fair amount of reading of veterinary medicine, the book is a revelation of the many infectious diseases to which domestic animals are subject. It is not out of place to repeat here the often given warning concerning the number of diseases which are transmissible from the lower animals to man, and the large

part which veterinary bacteriology and veterinary medicine in general play in the health and welfare of the human race.

The text is well documented, the references being conveniently placed at the end of each chapter. The printing is good. An excellent Table of Contents and a good index add to the practical value of the text.

MAZŸCK P. RAVENEL.

Infant and Child in the Culture of Today—the Guidance of Development—By *Arnold Gesell, M.D., and Frances L. Ilg, M.D., with the collaboration of Janet Learned, M.A., and Louise B. Ames, Ph.D.* New York: Harper, 1943. 399 pp. Price, \$4.00.

Arnold Gesell and his colleagues have produced another unique volume based upon their exhaustive studies in the Yale Clinic of Child Development. This time, however, the material is presented in such a manner as to be of considerable practical value to parents and child welfare workers alike. It is permeated with a philosophy which has a distinct value in orienting our present-day culture toward democratic ideals as opposed to a totalitarian type of culture. The chain of evidence running through the entire volume is linked to the theme—"This volume conceives cultural guidance in terms of the optimal needs of the individual organism. The cultural pattern must be adapted to the growth pattern because in the final analysis all individual development depends upon intrinsic self-regulation. There is no adjustment to culture other than self-adjustment" (page 53).

Part One of this fascinating book deals with Growth and Culture and considers "The Family in a Democratic Culture" as well as "The Personality and Acculturation" of the child. "The Cycle of Child Development" concludes this section.

Part Two takes up systematically The Growing Child in successive stages of growth and development. It is divided in a way to be especially helpful to parents by outlining the behavior profile for each age period followed by the various functions carried out in a Behavior Day.

In Part Three the Guidance of Growth is presented in a series of chapters taking up in considerable detail sleep, feeding, bowel and bladder control, personal and sex interests, self-activity, sociality and self-containment.

The Appendix is designed to be practical and helpful for all those concerned with child care. It gives a Behavior Day Chart for Self-Regulation Scheduling; lists of toys, play material and equipment, books for preschool children, and musical records for infants and young children. A well chosen list of selected readings concludes this part. The illustrations and line drawings have been selected with care, and a comprehensive index is included.

This is a volume that can be read from cover to cover with rapt attention and with great profit. The publishers are to be commended for the excellent format and illustrations.

RICHARD A. BOLT

Manual of War-time Hygiene: A Supplement to a College Text-book of Hygiene—By Dean Franklin Smiley, M.D., and Adrian Gordon Gould, M.D. New York: Macmillan, 1942. 86 pp. Price, \$1.00.

In a short booklet the authors, from the Department of Hygiene and Preventive Medicine at Cornell University, Ithaca, N. Y., aim to redirect and reorient the college student's work in the field of hygiene. This is because today the students are definitely preparing themselves for commissions in the armed forces or for equally important positions in civil life during the

greatest of all wars. Personal hygiene, always important, takes on added significance for the collegian who on graduation may be assigned the responsibility for the health and well-being of groups of soldiers or other military personnel. The pamphlet seeks particularly to give the college man a summary of and reading references related to the matters of hygiene of import to an officer in military service.

The greater portion of the text deals briefly with elementary military hygiene, fitness for service, the prevention of specific diseases by vaccination or inoculation, camp sanitation, nutrition, the organization of military medical care, recreation, and the battle against the venereal diseases. There follows a short section on civilian defense with emphasis on the emergency medical services and the problems of chemical warfare. The third main segment of the booklet is devoted to war-time first aid and this is followed by appendix material on artificial respiration. There is a good bibliography that should be relied upon heavily by any student who desires to take the matter of hygiene seriously in times of war.

The short hour or two needed for a thorough study of the pamphlet will well repay any college man. The pages devoted to the insect-borne diseases and the combat against the venereal diseases are among the best in the volume. Everyone should know the matter presented in regard to chemical warfare and first aid. If the authors have compiled their matter to a large degree from available authoritative documents, there can be no particular objection to this. However, while it is recognized that civilian medical service will be limited in war-time, it may be a bit severe to put the "must" in the expression, "The military forces must have 6 or 7 physicians for each 1,000 officers and men."

HUNTINGTON WILLIAMS

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Preventive Measures against Keratoconjunctivitis—This committee report sets forth the present-day understanding of the nature, the clinical course, the treatment, period of infectivity, and preventive measures against epidemic keratoconjunctivitis.

ANON. Epidemic Keratoconjunctivitis. J.A.M.A. 121, 14:1153 (Apr. 3), 1943.

Rural Sewage Disposal—Recommendations of a notable committee on rural sanitation will serve as a guide to satisfactory field practice concerned with sewage disposal methods. Working drawings for the construction of acceptable home disposal plants are included.

ANON. Recommendations of Joint Committee on Rural Sanitation-Rural Sewage Disposal. Pub. Health Rep. 58, 11:417 (Mar. 12), 1943.

They Still Need Help—Though the amount of money available for food does influence the quality of the meals, it was found in this survey that nearly half the families, which spent enough for the table, still had poor diets. Instruction is still badly needed in the newly self-sufficient families, even those in which someone has learned to prepare a suitable diet for a tuberculous patient, for this knowledge seems to have little effect upon the family dietary pattern.

DOWNES, J. Recent Changes in Income and Food Expenditures among Tuberculous Families in Harlem (and) A Study of Food Habits of Tuberculous Families in a Harlem Area of New York City. Milbank Quart. 21, 2:158 (Apr.), 1943.

Healthy Hearts Behave Variously—In normal young men pulse or blood

pressure, at rest, is not indicative of ability to work. Estimates of capacity for hard muscular work should be based upon ability to do it, and speed of recovery of heart after the exercise.

BROUHA, L., and HEATH, C. W. Resting-Pulse and Blood-Pressure Values in Relation to Physical Fitness in Young Men. New Eng. J. Med. 228, 15: 473 (Apr. 15), 1943.

About Lead Poisoning—As these are the days of industrial hygiene's glory, it would seem that the attention of all health workers should be called to six important papers on the industrial health hazard of lead poisoning. Only the first is listed below, because of the limitations of space, not because it should be singled out for mention.

BUXELL, J. The Measurement of Industrial Lead Exposures in Air Analysis (and five papers on other aspects of lead poisoning). J. Indust. Hyg. & Toxicol. 25, 2:35 (Feb.), 1943.

Once Upon a Time—When we had nurses to spare, the ailing well-to-do's were coddled by the private duty nurse, and the ain't-got-nothing's called in the visiting nurse, but the in-betweens had less nursing service than high or low income groups. Somebody should have told Mrs. Middle Income that she too could have the services of the visiting nurse.

COLLINS, S. D. Variations in Nursing Service with Family Income and Size of City. Milbank Quart. 21, 2:188 (Apr.), 1943.

Coliform Test Gets Court K. O.—Maybe you had better study this report yourself, but it seems that occasional cases of typhoid fever undoubtedly are due to public water supplies which meet approved standards, and that a

factor of safety provided by millions of coliforms per each *Eberthella typhosa* might help to improve this situation.

KEHR, R. W., and BUTTERFIELD, C. T. Notes on the Relation between Coliforms and Enteric Pathogens. Pub. Health Rep. 58, 15:589 (Apr. 9), 1943.

What's Past Is Prologue—Here you will find an answer to the question "How well educated were the nurses of 1941?" In a nutshell, it is "Pretty well, I thank you."

LANDAN, H. Academic Qualifications of Registered Nurses as Revealed by the 1941 National Survey of Registered Nurses. Pub. Health Rep. 58, 12:465 (Mar. 19), 1943.

Tuberculosis in Teachers—In the city of Quebec and in the year 1940, and in a group of school teachers, 16 were found tuberculous; most were in an early stage of the disease and were unaware that they were a danger to the pupils. The following year a Provincial law was passed requiring x-raying of all teachers. This time 128 were found to have active tuberculosis of the lungs, 176 non-active, and 484 more needing observation.

LA BERGE, L. Detection of Tuberculosis in School Teachers in the Province of Quebec. Canad. Pub. Health J. 34, 3:121 (Mar.), 1943.

Cheerful Note —Excellent results were obtained in the sulfonamide treatment of gonococcal ophthalmia neonatorum—93.8 per cent recovering with normal eyesight. However, exacting pediatric and nursing care are matters still of great importance.

LEVIN, I. M., and BLATT, M. L. Gonorrheal Ophthalmia Neonatorum. Am. J. Nurs. 43, 4:351 (Apr.), 1943.

The "Must" of the Month—Very emphatically, you must read all the leading articles in the May 1 issue of the J.A.M.A. Eleven papers are too many to mention individually in this crowded bibliography, but a partial list

of subjects—tropical diseases, epidemic influenza, malaria, nutritional diseases, trends in scientific research, health as a world problem, and inter-American coöperation—will indicate to you the necessity of reading them all, thoughtfully and immediately.

MACKIE, T. T., *et al.* Papers Read before the National Conference on Planning for War and Post-War Medical Services. J.A.M.A. 122, 1:1 (May 1), 1943.

As Others See Us—Praise-Singing Department—An English visitor charitably tells all that he found good in our courses in public health—both in undergraduate and in graduate medical schools—and concludes that the British educational practice may have something to learn from us.

MACKINTOSH, J. M. The Teaching of Preventive Medicine in the United States. Public Health. 56, 6:65 (Mar.), 1943.

"Boilermaker's Ear"—Plastic ear plugs molded to fit the individual's ear canal are suggested for workers in noisy industries. These plugs shut out the ear shattering, deafening, high-frequency noises, yet permit conversation.

MCCOY, D. A. The Prevention of Ear Disability in Industry. J.A.M.A. 121, 17:1330 (Apr. 24), 1943.

Glad Tidings for the Middle Aged—Hypertension is so common after 40 that a "moderate" degree can no longer be considered abnormal. Normal limits should be raised, concludes this paper.

MASTER, A. M., *et al.* Hypertension in People of Forty. J.A.M.A. 121, 16:1251 (Apr. 17), 1943.

"Them as Has, Gets"—There were fewer physicians per capita and a greater proportion of old-timers in poorer than in wealthy counties, and as might be expected, the rich counties are getting richer in young physicians and the poor, even poorer in all kinds.

MOUNTIN, J. W., *et al.* Location and Movement of Physicians, 1923 and 1938—Age Distribution in Relation to County Characteristics. Pub. Health Rep. 58, 12:483 (Mar. 19), 1943.

S. D. R. I. P.—Do you remember recent newspaper accounts of the "cure of cancer with egg white"? Well, here is a report that the treatment was with-

out effect upon two dissimilar cancer cases for which it was tried. This paper seems to indicate that what is needed these days is a S.D.R.I.P. (Society for the Discouragement of Rushing into Print).

RHOADS, C. P., and ABELS, J. C. The Administration of Egg White and Avidin Concentrates to Patients with Cancer. J.A.M.A. 121, 16:1261 (Apr. 17), 1943.

ASSOCIATION NEWS

THREE-DAY WARTIME PUBLIC HEALTH CONFERENCE AND SEVENTY-SECOND ANNUAL BUSINESS MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 12, 13, 14, 1943

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Dr. Fidel Alonso-Cainas, P. O. Box 415, Barce-
loneta, Puerto Rico, Director, Municipal
Hospital and Clinic Physician.
Rene F. Bruneau, M.D., D.P.H., Shefford Co.
Health Unit, Granby, Quebec, Canada,
Medical Officer.
Oscar W. Davison, M.D., 417-19 Huron Bldg.,
Kansas City, Kans., Asst. Director of
Health, City Health Dept.
George P. Gannon, M.D., 604 Glowood Drive,
Pittsburgh, 10, Pa., Director, Pittsburgh
Syphilis Control Program.
Francis A. Glass, M.D., 12 Main St., Haver-
straw, N. Y., Health Officer, West Haver-
straw.
James F. Hawkins, D.D.S., M.P.H., 8026
Sangamon St., Chicago, Ill., Dental Health
Officer, Cook County.
Donald J. Hunt, M.D., 1146 Flood Bldg., San
Francisco, Calif., District Medical Director,
U. S. Indian Service.
George James, M.D., Obion County Health
Dept., Union City, Tenn., Director, Obion-
Lake Health Dist.
George M. Jewell, M.D., 1455 Cypress, Paris,
Ky., Director, Bourbon County Health
Dept.
Nathaniel Jones, M.D., 700 W 10th St., Jack-
sonville, Fla., Director, City-County Ven-
ereal Disease Clinic, P.A. Surgeon(R)
U.S.P.H.S.
Raymond M. Lauer, M.D., 525 W. Market
St., York, Pa., Director of Public Health,
Dept. of Public Safety.
Heinz W. Markwald, M.D., Steele Road, New
Hartford, Conn., Health Officer.

Abraham Pressman, M.D., Colorado River
Relocation Project, Poston, Ariz., Director
of Health and Sanitation.
Robert S. Quinn, M.D., 816 Fourth St., Santa
Rosa, Calif., Asst. Health Officer, Sonoma
County.
Camerino Rodriguez-Lopez, M.D., C.P.H.,
Centro de Higiene, Taxco, Guerrero, Mex-
ico, Medical Officer of Health.
Martin H. Seifert, M.D., 1159 Wilmette Ave.,
Wilmette, Ill., Commissioner of Public
Health.
Mark T. Sheehan, M.D., 245 Center St., Wal-
lingford, Conn., Health Officer.
Joseph J. Smith, M.D., 1280 Stratfield Road,
Bridgeport, Conn., Health Officer, Town
of Easton.
Reuben Thalberg, M.D., 32 N. Main, South-
ington, Conn., Health Officer.

Laboratory Section

Gladys E. Duffy, M.A., Jeffery Hale's Hos-
pital, Quebec, P. Q., Canada, Technician.
Elizabeth A. Garrison, 215 E. 12th St., Marys-
ville, Calif., Laboratory Technician, Sutter-
Yuba Bi-County Health Unit.
Faith F. Gaston, M.S., Health Dept., Court
House, Kelso, Wash., Senior Bacteriologist.
Nancy K. V. Green, M.S., State Hygienic
Laboratory, Jackson, Miss., Bacteriologist.
Thomas G. Maynard, State Dept. of Public
Health, Springfield, Ill., Asst. Milk Sani-
tarian.
Lieut. Thomas W. Mou, M.A.C., Base Hos-
pital, Army Air Base, Alliance, Nebr.,
Laboratory Officer.

Vital Statistics Section

Paul W. Shipley, New Orleans, La., Assoc., Public Health Representative, U.S.P.H.S., and Chief, Tabulation Section, State Dept. of Health.

Engineering Section

Cleon C. Bullock, 144 Wilbur St., Mesa; Ariz., Sanitary Officer, Mesa Health Dept.
 R. C. Burkhardt, Mims Court, Huntsville, Ala., Senior Sanitarian, State Health Dept.
 Duard F. Campbell, Dept. of Public Health, Boise, Ida., Milk Sanitarian.
 Walter M. Culley, C.E., Surgeons Office, Second Service Command, Governors Island, N. Y., Sanitary Engineer.
 Theodore C. Hill, C.E., 144 East Main St., North East, Pa., Design Engineer, Gannett, Eastman & Fleming.
 Prof. Edward J. Kilcawley, M.C.E., Rensselaer Polytechnic Institute, Dept. of Civil Engineering, Troy, N. Y., Professor of Soil Mechanics and Sanitary Engineering.
 Howard McGuire, 509 W. Clark St., Champaign, Ill., Sanitarian, State Dept. of Public Health.
 Alfred H. Paessler, M.S., 4300 Avenue D., Austin, Tex., Acting Supt. of Water and Sewage Treatment Plants.
 Joseph Allen Radbury, 1432 E. McKinley, Phoenix, Ariz., Sanitary Food Inspector, City Health Dept.
 Roy Edwin Ramseier, C.P.H., 852 S. 19th East, Salt Lake City, Utah, Senior Sanitary Engineer, Pacific Division, U. S. Eng. Dept.
 Perry C. Sharp, 852 U. S. Custom House, Chicago, Ill., Asst. Sanitary Engineer (R) U.S.P.H.S.
 C. H. Watson, Bannock County Health Unit, Pocatello, Ida., Sanitarian.

Industrial Hygiene Section

Capt. Thomas F. Feltz, M.C., Desert Chemical Warfare Depot, Tooele, Utah, Director of Industrial Hygiene and Post Surgeon.
 Edwin C. Hyatt, 1902 N. Circle Drive, Jefferson City, Mo., Industrial Hygiene Engineer, State Board of Health.
 Melville H. Manson, M.D., 140 West St., New York, N. Y., Medical Director, New York Telephone Co.
 Margaret J. Nicols, M.A., Div. of Industrial Hygiene, State Dept. of Labor, Syracuse Univ., Syracuse, N. Y., Assoc. Public Health Nursing Consultant, U.S.P.H.S.
 Hugh L. Parker, M.S., 143 Lyle St., College Park, Ga., Industrial Hygiene Chemist, Industrial Hygiene Service, State Health Dept.
 Capt. John J. Ritter, M.A.C., APO 837, c/o Postmaster, New Orleans, La., Venereal Disease Control, U. S. Army.

Bonnie J. Sewell, R.N., 1050 Gaviota St., Long Beach, Calif., Student.

Food and Nutrition Section

Dr. Oswaldo Lopes da Costa, National Dept. of Health, Praca Mal Ancora, Rio de Janeiro, Brazil, S. A., Chief, Section on Nutrition.
 Earl A. Louder, Ph.D., Pet Milk Co., Greenville, Ill., Technical Director.
 Mabel Perry Polan, M.S., State Health Dept., Austin, Tex., Senior Nutritionist.
 Harold R. Sandstead, M.D., 15 Pine St., Sub-Treasury Bldg., New York, N. Y., P.A. Surgeon, U.S.P.H.S.
 Paul F. Sharp, Ph.D., 425 Battery, San Francisco, Calif., Director of Research, Golden State Co., Ltd.
 John M. Sherbeck, Health Dept., City Hall, Bay City, Mich., Sanitarian.
 Ansta Todd, M.S., Capitol Annex Bldg., Phoenix, Ariz., Nutrition Consultant, State Dept. of Health.
 Eleanor M. Wilkinson, M.S., State Board of Health, State House, Dover, Del., Nutritionist.

Maternal and Child Health Section

Wesley N. Segre, M.D., Flint-Goodridge Hospital, New Orleans, La., Obstetrician, School of Nurse-Midwifery.
 Mary E. Soules, M.D., M.P.H., 504 3rd St., Bismarck, N. D., Asst. Director, Maternal and Child Health, State Dept. of Health.

Public Health Education Section

Lillian C. Christensen, M.Ed., 133 Dorchester St., South Boston, Mass., Health Educator, Boston Health Dept.
 Armand J. Courchaine, R.N., 4516 Baltimore Ave., Philadelphia, Pa., Science Instructor, Hahnemann Hospital School of Nursing.
 Alma B. Fringer, 216 Rockford News Tower, Rockford, Ill., Exec. Secy., Winnebago County Tuberculosis Assn.
 Alice M. Heath, 1018 N. Jefferson St., Milwaukee, Wis., Health Education Consultant, Wisconsin Anti-Tuberculosis Assn.
 Ellen Kuhlmann, Box 544, Sharon, Pa., Exec. Secy., Mercer County Tuberculosis and Public Health Society.
 Helen P. Olmstead, R.N., C.P.H., Room 401, P. O. Bldg., Oklahoma City, Okla., Field Nurse Supervisor, U. S. Indian Service.
 Russell E. Shrader, M.A., 812 Littlefield Bldg., Austin, Tex., Merit System Supervisor, State Dept. of Health.
 Taylor Smith, M.D., 35790 Detroit Rd., Avon, Ohio, Member, Lorain County Health Committee.
 Ella T. Whitten, R.N., City Health Dept., 9

Ontario St., Toledo, Ohio, Supervisor of School Nursing.

Public Health Nursing Section

Mabel F. Chrystie, R.N., 519 Smithfield St., Pittsburgh, Pa., Asst. Director, Public Health Nursing Assn.

Gertrude M. Clouse, R.N., State Board of Health, Fond du Lac, Wis., State Advisory Nurse.

Evelyn A. Conner, R.N., 302 N. Madison St., Quitman, Ga., Brooks County Health Nurse.

Mary McR. Corpening, R.N., 206 S. John St., Goldsboro, N.C., Supervising Nurse, Wayne County Health Dept.

Neoma S. Crynock, R.N., 436 Stewart St., Morgantown, W. Va., Industrial Nurse, Koppers Coal Co.

Avis J. Dykstra, R.N., Martha Cook Bldg., Ann Arbor, Mich., Student, Univ. of Michigan.

Edith J. Eyester, R.N., 808 N. Spring St., Los Angeles, Calif., Supervising Public Health Nurse, Los Angeles County Health Dept.

Florence Cox Goodwin, R.N., 1304 Main St., Clarkdale, Ariz., Public School Nurse.

Helen L. Hendricks, R.N., Tishoming County Health Dept., Iuka, Miss., Staff Nurse.

Geraldine Hiller, M.A., Johnson Road, Falmouth Foreside, Me., Supervisor, Div. of Nursing, State Bureau of Health.

Pearl S. Kirkpatrick, R.N., Nevada St., Gooding, Ida., Gooding County Public Health Nurse.

Claudia M. D. Mangham, 419 E. 48th Place, Chicago, Ill., Public Health Field Nurse, Cook County Public Health Unit.

Vera E. Roswell, 110½ W. Oak St., Sparta, Wis., Advisory Public Health Nurse, State Board of Health.

Mildred B. Saunders, 816 Montrose Drive, South Charleston, W. Va., Industrial Nurse, Westvaco Chlorine Products Corp.

Leta Seaman, 1145-66th St., Des Moines, Ia., Consultant Nurse, State Dept. of Health.

Florence M. Watson, 11 Philadelphia Ave.,

Takoma Park, D. C., Staff Nurse, Instructive Visiting Nurse Society.

Helen L. Woodworth, 1337 Linda Vista Ave., Pasadena, Calif., Director of Nursing Service, Pasadena Visiting Nurse Assn.

Epidemiology Section

LeRoy D. Fothergill, M.D., U. S. Naval Medical Center, Bethesda, Md., Head, Dept. of Epidemiology.

Gerald F. Gagnon, 414 Walnut, Buena Park, Calif., Qualified Asst., Epidemiology-Sanitation, U. S. Navy.

Luis De J. Lozano-Mendoza, Calle Sta. Maria la Ribera 1-A, Mexico City, Mexico, Supervisor, Public Health Dept., Zone VIII (States of Michoacan and Guerrero).

Unaffiliated

Ernest G. Lion, M.D., 33 Hunt St., San Francisco, Calif., Director, Psychiatric Service, City-County Health Dept.

Philip Lomas, 122 W. 69th St., Los Angeles, Calif., Meat Inspector, City Health Dept.

Russel G. Means, M.D., 40 S. 3rd St., Columbus, Ohio, Member, Ohio Public Health Council.

Lawrence E. Shulman, 290 Congress Ave., New Haven, Conn., Research Assoc., Laboratory of Hygiene, John B. Pierce Foundation.

Richard M. Starr, M.D., 45 Huntington St., New London, Conn., Health Officer, Town of Waterford.

A. C. Woofert, M.D., State Dept. of Health, Des Moines, Ia., Acting Director, Division of Venereal Disease Control, State Dept. of Health, P.A. Surgeon, U.S.P.H.S.

DECEASED MEMBERS

A. Grant Fleming, M.D., D.P.H., McGill University, Montreal, Canada. Elected Member 1920, Elected Fellow 1930, Elected Life Member 1934, Epidemiology Section.

Paul D. Robason, M.D., McKinney, Tex. Elected Member 1942, Health Officers Section.

SCHOOL HEALTH SECTION WORKSHOPS

Establishment of a new Section on School Health by action of the Governing Council has already been announced. The officers of the Section, Leona Baumgartner, M.D., *Chairman*, and George M. Wheatley, M.D., *Secretary*, hope to have as an essential feature of the Section's activities workshops which will deal with fundamental "grass roots"

problems of school health. They invite members of the Association to contribute suggestions for the future work of the Section and for specific problems in which they would be willing to contribute materials and work actively. Send suggestions directly to Leona Baumgartner, M.D., Department of Health, 125 Worth Street, New York, N. Y.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations

will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Wanted: School Dental Supervisor to administer and operate dental program in City schools and clinics in City of 50,000 population. Salary \$3,000 to \$3,600 with travel allowance. Those interested should address Dr. W. A. Browne, City Health Department, Alexandria, Va.

The Milwaukee City Service Commission announces an examination for assistant chief in charge of sanitary inspection. Salary first year \$210 per month increasing by \$10 increments annually until a maximum of \$260 per month is reached. Applicants must be citizens of the United States, between 25 and 45 years of age. Those interested may communicate with the Milwaukee City Service Commission, Room 716, City Hall, Milwaukee, Wis.

AMERICAN SOCIAL HYGIENE ASSOCIATION
NEW STAFF MEMBERS

Raymond H. Greenman,* assigned as field consultant in one of the Army Service Commands. Mr. Greenman has been in public health work since 1919, serving 19 years as executive secretary of the Tuberculosis and Health Association of Rochester and Monroe County, N. Y., and for 10 years also as executive secretary of the Medical Society of the County of Monroe.

Wade T. Searles, assigned as field consultant in one of the Army Service Commands. Mr. Searles was formerly a senior adviser on war services for the Office of Civilian Defense and a member of the faculty of Indiana University, and has had wide experience in welfare and public health fields while employed by the unemployment and transient relief agencies in Dayton, Ohio; the Dayton Public Health Clinic; and the Indiana State Conference on Social Work.

Edna W. Fox, R.N., M.P.H., assigned as field consultant in one of the Army Service Commands. Since 1914 Mrs. Fox has been engaged in work with the Rockefeller Institute, the American Red Cross, the American Tientsin School in Tientsin, China, and assisting her husband, Brig. Gen. A. Fox, M.C., in editing and publishing articles on epidemiology and preventive medicine.

Charles E. Miner, assigned as field consultant in one of the Army Service Commands. Mr. Miner was in charge of the venereal disease control program in all extra-cantonment areas in five southeastern states in World War I and later served as executive officer of the Committee of Sixteen at Erie, Pa.; the Missouri Social Hygiene Association; and as General Director of the Committee of Fifteen at Chicago. More recently he has been State WPA Administrator for Illinois, Regional Director for 13 central states of the Post War Program for state and local works,

and field representative for the Illinois Emergency Relief Commission.

Josephine D. Abbott, assigned as consultant to study delinquency problems. Mrs. Abbott comes to the association from the Division of Child Hygiene of the Massachusetts State Department of Health, where she was a consultant in parent education. As director of the Family Information Center at the Jordan Marsh Company in Boston; and as a clinical psychologist and educational lecturer; consultant in child management; Mrs. Abbott has special experience in the field of parent education, child psychology, and child guidance.

Thomas A. Larremore, assigned as legal consultant at American Social Hygiene Association headquarters. Mr. Larremore, a lawyer, served on the staff of the association from 1917 to 1920, and in the United States Army. He has been a member of the faculties of several law schools. He comes to the association again from private legal work.

Kenneth Miller,† assigned to a special education project is loaned to the association on a part-time basis by the Philadelphia Tuberculosis and Health Association, where he is director of the local educational and publicity program.

Shirley Greene,† assigned to work in the association's publication division was formerly with the Queensboro Tuberculosis and Health Association and the Newburgh Public Health and Tuberculosis Association. Mrs. Greene is a graduate of Hunter College and the Yale School of Public Health.

Isabel H. Collins, assigned to do educational work with Dr. Snow and Professor Bigelow. Mrs. Collins formerly was Assistant to the Secretary of the Social Hygiene Committee of the New York Tuberculosis and Health Association and comes to the association from Washington, D. C., where she worked as Health Education As-

sistant of the Social Hygiene Society of the District of Columbia.

UNIFORM DEFINITIONS OF MOTOR VEHICLE ACCIDENTS

The U. S. Department of Commerce has announced the publication of a pamphlet on Uniform Definitions of Motor Vehicle Accidents which was prepared under the supervision of Halbert M. Dunn, M.D., Chief Statistician for Vital Statistics of the Bureau of the Census, by Iwao M. Moriyama, Associate Biometrician. The Committee on Definitions of the National Conference on Uniform Traffic Accident Statistics included Dr. Dunn as Chairman, Dr. Earle G. Brown of Mineola, N. Y., Dr. E. R. Coffey, Assistant Surgeon General, U. S. Public Health Service, Dr. Edward S. Godfrey, Jr., New York State Commissioner of Health and Robert J. Vane of the Metropolitan Life Insurance Company representing the American Public Health Association, among others.

This report, which is available through the Bureau of the Census for distribution, has been approved by the American Public Health Association, the American Association of Motor Vehicle Administrators, the Conference of State and Provincial Health Authorities of North America, and the U. S. Public Health Service, among other agencies.

A STUDY OF MEDICINE AND THE CHANGING ORDER

The New York Academy of Medicine has announced the formation of a committee whose objectives will include being informed on the quality and direction of the economic and social changes that are taking place now and that are clearly forecast by the immediate future. The result will help to define how these changes are likely to help medicine in its various aspects and to determine how the best elements of the

science of medicine and its service to the public may be preserved and embodied in whatever changed social order may ultimately develop.

The Chairman of the committee is Dr. Malcolm Goodridge and among members are the following with interests in public health: James Alexander Miller, M.D., Alan Gregg, M.D., George Baehr, M.D., I. Ogden Woodruff, M.D., Wilson G. Smillie, M.D., Jean Curran, M.D., and Iago Galdston, M.D., Secretary.

AWARD TO DR. FLORENCE SEIBERT

The American Association of University Women has announced the presentation in April of its first Achievement Award in the amount of \$2,500 to Dr. Florence Seibert, Associate Professor of Biochemistry in the Phipps Institute, University of Pennsylvania. Dr. Seibert for years has been active in research relating to tuberculosis and in particular in the preparation of the purified protein derivatives.

THE BELA SCHICK LECTURES

The first Bela Schick lecture under a fund created in 1942 by the friends and associates of Dr. Bela Schick, New York, N. Y., was presented recently at Mt. Sinai Hospital, New York, by William E. Ladd, M.D., Professor of Child Surgery in the Harvard Medical School, Boston, on the subject of Time and Choice of Operation in Early Life.

NICHOLAS APPERT MEDAL AWARDED TO PROFESSOR S. C. PRESCOTT

The Chicago Section of the Institute of Food Technologists has announced that its Nicholas Appert Medal has been awarded to Professor Samuel Cate Prescott, Emeritus Dean of Science, Massachusetts Institute of Technology, Cambridge. The medal is to be presented on June 3 at the meeting of the Institute in St. Louis, Mo.

Since his retirement in June, 1942, as

Dean of Science at M.I.T., Professor Prescott has been called in to consulting service by the Dehydration Committee of the U. S. Department of Agriculture and by the Research Laboratories of the National Canners Association.

U. S. PUBLIC HEALTH SERVICE FEATURED
IN RKO "THIS IS AMERICA" FILM

Dr. Carl E. Rice, currently in charge of the Community Medical and Dental Section of the U. S. Public Health Service at Bathesda, Md., is featured in RKO's "Medicine On Guard," which tells the story of the typical wartime community faced by urgent health problems arising from the shortage of doctors. Dr. Rice works in close coöperation with the Procurement and Assignment Service of the War Manpower Commission and, on request will arrange the relocation of a doctor from a less critical area. This latest "This Is America" two reel feature depicts the rising incidence of tuberculosis in a typical industrial community. Under the direction of Dr. Herman E. Hilleboe, this menace is being checked through the use of the mobile photo-fluorographic units which are set up in the factories themselves and take chest plates of the workers with a minimum of time loss and expense. The elaborate laboratories of the Division of Industrial Hygiene under the direction of Dr. James G. Townsend are shown determining the causes of occupational disabilities.

DR. WILINSKY RECEIVES BOSTON CITY
CLUB MEDAL

Charles F. Wilinsky, M.D., Chief Medical Officer of the Boston Public Safety Committee, Director of Beth Israel Hospital, and Deputy Commissioner of Health of Boston, was recently awarded the medal of the Boston City Club for "most outstanding civic service to Greater Boston in 1942."

This medal is presented annually to

the resident of Greater Boston not holding an elective position, who has performed in the opinion of the club the most meritorious service for the welfare of Bostonians. The selection of Dr. Wilinsky was the outcome of his work in organizing the medical section of the Boston civilian defense effort and for his work during the Cocoanut Grove disaster.

UNIVERSITY OF TEXAS RECEIVES GRANT
FOR CHILD HEALTH

The William Buchanan Foundation of Texarkana has announced a grant to the University of Texas Medical School of \$200,000 covering a 5 year program on child health. It is reported that the program will be worked out in conjunction with the Department of Pediatrics which will correlate the work of other state and national agencies. "Its purpose is to afford the profession in Texas an opportunity to maintain the latest methods in connection with the promotion of child health, especial attention to be given to the problems of the adolescent in wartime."

CHARLES F. BOLDUAN, M.D., RETIRES

The retirement of Charles F. Bolduan, M.D., as Director of the Bureau of Health Education in the New York City Department of Health, effective June 1, has been announced. On May 20 his friends and associates tendered to Dr. Bolduan a dinner in his honor in New York.

OCD PLAN FOR EMERGENCY MEDICAL
SERVICE IN INDUSTRIAL PLANTS

Emergency Medical Service for Industrial Plants, a new bulletin issued by the Medical Division of the Office of Civilian Defense, advises every plant medical department to prepare a "disaster operations plan" to provide adequate medical service in case of a plant catastrophe involving large numbers of casualties.

The plan should provide for necessary first aid care at the site of the incident, for adequate ambulance service, and for hospitalization of the seriously injured, it is stated.

The bulletin discusses casualty stations, the importance of identification and records, transportation, the organization and operation of protective services in a community, and the overall protective services recommended for industrial plants. A bibliography of pertinent material is included.

SURGEON GENERAL'S ANNUAL REPORTS DISCONTINUED

Dr. E. R. Coffey, of the Division of Sanitary Reports and Statistics, U. S. Public Health Service, announces the decision of the Office of War Information to suspend publication of the *Annual Reports of the Surgeon General* for the duration of the war.

OFFICE OF COMMUNITY WAR SERVICES ESTABLISHED

By executive order of the President on April 30, the Office of Community War Services was established in the Federal Security Agency, eliminating the Office of Defense Health and Welfare Services. Federal Security Administrator Paul V. McNutt has announced that Charles P. Taft becomes Director of Community War Services in the new organization.

The Office of Community War Services, like its predecessor, is the federal agency concerned in health, medical care, welfare, recreation, education, and related services. It includes Divisions for Recreation, Social Protection, and Day Care for children of women in war work. It also serves as the center for coordinating health and welfare services available through federal and other public and private agencies which can help communities meet wartime needs in these fields; and offers states and localities the services of health and wel-

fare specialists to assist in planning and developing their community programs.

The President's executive order also established a Committee on Physical Fitness in the Federal Security Agency. John B. Kelly is Chairman. The committee is charged with carrying on a nation-wide promotional program, in cooperation with national, state, and local organizations, and for providing advice and assistance to communities in developing and carrying out plans to promote the interest of individuals in improving their own physical condition.

NEW DUTIES FOR CIVILIAN PHYSICIANS ORGANIZED FOR CIVILIAN DEFENSE

Temporary assistance to the Army if it is unable to handle a sudden influx of war casualties or some other military emergency in War Department hospitals will be given by units of civilian physicians organized for Civilian Defense. "Affiliated hospital units" have already been organized by OCD and the U. S. Public Health Service in coastal areas, and will be expanded to include more than 200 hospitals throughout the country, at the request of the War Department. Each unit consists of 15 doctors normally associated with a single hospital, and the units will be used in military emergencies in or near the communities in which the staff resides.

Physicians accepted for service with the affiliated hospital units receive reserve commissions in the U. S. Public Health Service, but will be called to active duty by the Surgeon General only at the call of the OCD. When a unit is needed, either to staff an OCD emergency base hospital or to assist the Army temporarily in a military emergency, the physicians of the unit will be placed on active duty for the duration of that particular emergency, and receive the pay and allowance of medical officers of equivalent rank in the Army. They will return to inactive

status as soon as they can be replaced by Army medical officers.

Initially, only hospitals and medical schools in the areas considered in most immediate danger of enemy attack were invited to form these units, but to meet the Army's request for their availability in an unexpected emergency, such units will now be formed throughout the country.

Dr. George Baehr, Chief Medical Officer of the U. S. Office of Civilian Defense, reported that, by April 22, unit directors had been nominated by 152 of the hospitals and medical schools in coastal areas previously invited to form units, and that 104 of these had been commissioned.

MANHATTAN COLLEGE FOOD HANDLING COURSE

On June 7, a free course in sanitation problems in food handling and processing begins at the School of Engineering of Manhattan College, New York, N. Y. It will run for 6 weeks. The course is under the educational supervision of Dr. J. H. Shrader, and is conducted in coöperation with the Department of Health of the City of New York. Its purpose is to offer training in methods of food technology and sanitation as a means of increasing food production and preventing spoilage, contamination, and food poisoning. Persons who satisfactorily complete the course will be issued a Qualifying Certificate in Food Sanitation by the City Department of Health.

"FOR THIS WE FIGHT"

The Commission to Study the Organization of Peace and the Twentieth Century Fund announce a series of broadcasts entitled "For This We Fight" beginning Saturday, June 5, 7:00 to 7:30 P.M. and continuing for a period of 26 weeks. Secretary of State Cordell Hull will be the first speaker. American statesmen, businessmen, labor lead-

ers, educators, scientists, and outstanding representatives in other fields will discuss crucial postwar problems over the National Broadcast Company network during the series. International aspects of the postwar world and the national postwar issues are the main themes. Business, labor, health, economic security, education, housing, public works and related questions will all be included in the discussion of postwar problems.

1943 AMENDMENTS TO THE PUBLIC HEALTH LAWS IN GEORGIA

Among the new statutes pertaining to public health in Georgia there are new laws and regulations governing shellfish sanitation, on simplified forms of birth certificates, on birth certificates for adopted children, the filing of delayed birth certificates, the provision of enlarged county boards of health, to require the examination of blood specimens from each pregnant woman, and to prevent the use of various premises for purposes of prostitution.

The Georgia State Board of Health recently has declared a quarantine on venereal diseases in Georgia and has promulgated rules for its enforcement. The official resolution declares that an epidemic of venereal diseases "of such proportions and widespread nature that it is a menace to the public health and safety" now exists in Georgia. The quarantine is imposed on persons with syphilis, gonorrhea, and chancroid, and on persons directly exposed to these diseases. Provisions are made for the establishment of isolation or detention hospitals for the detention and treatment of these persons.

RESOLUTION ON EMPLOYMENT OF WOMEN IN WARTIME

Frances Perkins, Secretary of Labor, Washington, recently called a Conference on the Employment of Women in Wartime which adopted resolutions

relative to standards and hours of employment. The conference endorsed state laws and regulations embracing the following basic principles, except where modification may be necessary during the war period to insure maximum production.

The conference urged that peacetime standards of hours and conditions of work in civilian industry be not relaxed in order to provide conveniences, goods, and services for war workers and civilians which in peacetime may be desirable but in time of war are not truly necessary to the national well-being. If relaxation of state labor laws should be necessary, it was urged that it should be granted only in those areas in which critical labor shortages exist and that it be permitted only for the production of goods and services necessary to provide for the basic minimum subsistence needs of war workers and the civilian population.

NEW STANDARDS

The American Standards Association announces that it has approved two new standards "Allowable Concentration of Chromic Acid and Chromates" and "Allowable Concentration of Mercury." These have been developed by the Subcommittee on Allowable Concentrations of Toxic Dusts and Gases—Z.37. The representative of the American Public Health Association on this Subcommittee is J. J. Bloomfield of the National Institute of Health. Copies of the standards may be obtained from the American Standards Association, 29 West 39 Street, New York, N. Y.

LIBRARIES AND THE WAR

"Information for Victory" is the theme of the short but important annual meeting of the Special Libraries Association which is to be held June 22-24 at the Hotel Pennsylvania, New York, N. Y. The slogan of the association has been "Putting Knowledge To Work."

One important field of knowledge is public health. In the association, libraries dealing with this subject are found in the Biological Sciences Group. This group is holding special meetings at the convention and also joining other groups which cover social science, technology, finance, insurance, etc.

Marion Kappes, Librarian of The Children's Memorial Hospital, Chicago, is Chairman of the Biological Sciences Group.

PERSONALS

Central States

GAYLORD W. ANDERSON, M.D., DR. P.H.,* MAJOR M.C., U.S.A., has been appointed head of the Division of Medical Intelligence in the office of the Surgeon General, U. S. Army. This division compiles health and sanitation information from the areas to which United States troops may be sent. Dr. Anderson is head of the Division of Preventive Medicine and Public Health at the University of Minnesota Medical School, Minneapolis.

WILLARD H. DOW, of Midland, Mich., President of the Dow Chemical Company, has been awarded the Charles Frederick Chandler Medal by Columbia University for noted achievements in the field of chemistry. The medal was established in 1910 in honor of Professor Chandler, who was a Founder of the American Public Health Association.

Brucellosis: Consideration of Its Epidemiology, Diagnosis and Control*

CARL F. JORDAN, M.D., M.P.H., F.A.P.H.A., IRVING H. BORTS, M.D., F.A.P.H.A., DONALD M. HARRIS, M.D., M.P.H., F.A.P.H.A., AND JAMES R. JENNINGS, C.E., F.A.P.H.A.

Epidemiologist, Iowa State Department of Health, Des Moines; Associate Director, State Hygienic Laboratory, Iowa City; Medical Director, District Health Service No. 3, Spencer; and Milk Sanitarian, Iowa State Department of Health, Des Moines, Iowa

DURING 1930-1941, there were reported in the 48 states of this country 29,594 cases of brucellosis, an average annual rate of 1.87 per 100,000 population.† Officially notified cases in Iowa totaled 1,887 for the same 12 year period, the average annual rate being 6.25 per 100,000.

Direct contact with infected animals and use of raw milk products from infected dairy cows provide the chief means of transmission to man of brucellosis or undulant fever. This statement applies to Iowa, probably also to many if not all of the cattle and hog raising states. As pointed out by Hardy and associates,¹ direct contact with hogs must be considered a major factor to account for the relatively high inci-

dence of brucellosis in the midwestern states of this country. Cases resulting from direct contact, whether with infected hogs or cows, are usually of sporadic nature; such cases in the aggregate, apparently exceed in number those traceable to contaminated dairy products.

Milk-borne brucellosis likewise, is nearly always of sporadic occurrence when *Brucella abortus*, the bovine type of organism, is the etiologic agent. On the other hand, when the porcine strain, *Brucella suis*, gains access to the udder of a dairy cow to contaminate a raw milk supply, multiple cases of the disease may be fully expected. This may be due to the fact that *Brucella suis* is more highly pathogenic than *Brucella abortus* and that the former multiplies more rapidly in a milk medium under ordinary atmospheric conditions than does the bovine strain of brucella.

Brucellosis lends itself favorably to epidemiologic study. The organism has

* Presented at a Joint Session of the Laboratory, Engineering, and Epidemiology Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

† A table containing annual reports from the 48 states covering the 12 year period 1930-1941 may be had on request of the Iowa State Department of Health, Des Moines, Ia.

distinct morphologic and cultural characteristics, and can readily be isolated from blood, although such isolation may require several weeks to a month or longer. Agglutination, intradermal and other tests are available to throw light on the nature of infection and immunity. The disease in the animal reservoir and in the experimental animal also affords opportunity for determination of virulence, manner of spread and source of infection.

It is desired in this report to limit consideration to milk-borne brucellosis; information as presented is based on an investigation of two cases caused by *Brucella abortus* in Madrid (Boone County), Iowa, and on the study of an epidemic in Marcus, Iowa, in which *Brucella suis* was the inciting agent.

MADRID INVESTIGATION AND SURVEY (BRUCELLA ABORTUS)

On July 2, 1942, Mr. A. L., 68, a resident of Madrid (Pop. 2,074), Boone County, Iowa, began to complain of tired feeling, pain in back of neck, fever (102°), chills and sweats. Three weeks later, the patient's serum was found to agglutinate brucella antigen in a dilution of 1:1,280. The patient gave no history of direct contact with farm animals, but during the months antedating illness, had used two glasses daily of raw milk from a local, the C. S., dairy. Through coöperative arrangement between the State Department of Health, the Bureau of Animal Industry, and the State Department of Agriculture, local veterinarians were authorized to obtain blood specimens from dairy herds which supplied milk in the community. Of 13 cows in the C. S. dairy, 9 proved to be reactors to the agglutination test for Bang's disease. The dairyman concerned, a thoroughly coöperative person, sold no milk to patrons after July 31. Other herds were not tested at the same time, due mainly to misunderstanding

on the part of producers with respect to accuracy of the agglutination test.

Although a blood culture from the patient failed to yield *Brucella abortus*, it is highly probable that infection was due to brucella of bovine type. This organism was later isolated from guinea pigs, following subcutaneous injection of cream from reactor cows.

While sporadic cases had developed from time to time in rural areas of the county, the case of brucellosis in Madrid was the first to come under observation of local physicians in a period of more than a decade. In addition to the patient, it was assumed that scores of children and adults in many homes had been exposed to the contaminated milk supply. With the interest and aid of local physicians, school superintendent, and parents, arrangements were made for blood specimens to be obtained for the agglutination test and for skin tests to be administered, using brucellergen. Such a survey was conducted in the school building on August 11, 1942, and again, for the most part on a different group, on September 29. Record was kept of the age and sex of volunteers, of residence in town or country, and of the source of milk supply.*

RESULTS OF AGGLUTINATION TESTS

The agglutination tests were carried out at the State Hygienic Laboratory, beginning with a titer of 1-5. The results as summarized for a group of 147 persons, are presented in Table 1. Males and females being considered equally susceptible to brucellosis of milk-borne character, the whole group was classified according to three age groups, 1-9, 10-19, 20 and over. Further classification was made under two headings, including on the one hand consumers of the "contaminated milk supply" and, on the other hand, those

* The authors desire to acknowledge the valued assistance in the investigation at Madrid of Glen M. Grout, Sup't of Schools, R. A. Gamble, M.D., M. Shaw, M.D., and J. O. Cook, M.D.

who had used "other milk supplies." "Other milk supplies" refers to five producers of raw milk and to "own cows" of those from the surrounding rural area.

It will be noted that among 63 users of the contaminated milk supply, 18, or 28.6 per cent, showed agglutination in titers ranging from 1:5 to 1:40, the titer of but one person being 1:40. Of 84 individuals of all ages, representing consumers of "other milk supplies," 17, or 20.2 per cent, showed positive agglutination, 16 in titers of 1:5-1:20 and one in the 1:40 dilution.

These results, based as they are on a comparatively small number of people, some of whom used milk and cream only sparingly, are hardly remarkable. A similar agglutination survey, in a sanatorium or institution with an abundant per capita use of raw milk from infected dairy cows, would probably be accompanied by more significant evidence of latent infection.²

RESULTS OF SKIN TESTS

Intradermal tests were administered with brucella nucleoprotein, known as brucellergen and made according to the method of I. Forest Huddleson, D.V.M., Research Professor in Bacteriology, Michigan State College, East Lansing, Mich. Two types of antigen were supplied for this survey through the courtesy of Dr. Huddleson, prepared separately from *Brucella abortus* (dilution 1:12,000) and *Brucella suis* (1:4,000). Each person received two intradermal tests (0.1 ml.) on the inner aspect of the forearm, brucellergen abortus above and brucellergen suis below. Each preparation was further diluted to 1:60,000 and 1:20,000 respectively to avoid the possibility of a severe reaction in those who might be markedly allergic.

Skin reactions were observed and measured after an interval of 48 hours, an area 2 x 2 cm. in diameter, with

redness, induration, and tenderness being recorded as positive. The results are set forth in Table 2. As in Table 1, those tested were divided into three age groups, 1-9, 10-19, 20 and above, and according to use of "contaminated" and "other milk supplies." Skin tests were performed on 170 volunteers. Among 71 who had used the contaminated milk supply, 10, or 14.1 per cent, had positive reactions; of 99 consumers of other milk supplies, 12 or 12.1 per cent, showed allergic response.

It is of interest to note that among 27 children of the age group 1-9, 13 of whom used the contaminated milk, all showed negative skin reactions.

There was no notable difference in size, redness, or induration between the reaction produced by brucellergen abortus and that resulting from brucellergen suis.

OCCURRENCE OF A SECOND CLINICAL CASE

Among those who participated in the agglutination and skin test survey on August 11 were Mr. and Mrs. D, aged 40+, residents of the city and exposed to the contaminated milk supply. Mr. D's agglutination test was negative, his skin tests strongly positive. Agglutination and skin tests were both negative in the case of Mrs. D, but she began to complain of fever and indisposition about September 1. On September 10, a second blood specimen showed agglutination of brucella in a dilution of 1:320, and the skin test had become positive. It seems probable that this woman carried a latent infection on August 11, in spite of negative skin and agglutination tests. Among 30 other individuals whose serum when taken August 11 showed no agglutinins or titers not higher than 1:5 or 1:10, 21, or 70 per cent, were entirely negative when the agglutination test was repeated on September 29.

MARCUS INVESTIGATION AND SURVEY (BRUCELLA SUIIS)

On September 10, 1941, investigation was made in Marcus (population 1,206), Cherokee County, Iowa, of 13 cases of brucellosis. These cases, verified by positive agglutination findings at the State Hygienic Laboratory, were reported by the local health officer and attending physician, to the District Health Service and to the State Department of Health. All of the patients gave the history of having been supplied with milk from the W. H. dairy, distributor of raw milk. Delivery of milk from this dairy was stopped September 10, 1941. In spite of early removal of the contaminated milk supply, additional cases came to attention through the remaining months of 1941. In the entire outbreak, 77 persons were found to have active or latent infection as confirmed by positive agglutination tests. Of a series of 29 blood cultures, 13 yielded brucella, all strains being identified as *Brucella suis*.

Agglutination tests for Bang's disease, performed on serum of cows in the W. H. dairy, showed three positive (and one suspicious) reactors. *Brucella suis* was isolated from the cream of two reactors. Hogs on the dairy farm were also found to be infected.⁴

The Marcus milk-borne epidemic caused by *Brucella suis* was the second of its kind to be investigated in Iowa; the first outbreak occurred in 1933 and was reported by Beattie and Rice.⁵

In order to obtain additional information as to the extent of infection in the Marcus community, blood specimens for agglutination were secured and skin tests performed on students and adults in the public and parochial schools.*

* Acknowledgment is made of the valued assistance in the investigation at Marcus of Father E. M. McEvoy, H. Wood, Sup't of Public Schools, and M. F. Joynt, M.D.

RESULTS OF AGGLUTINATION TESTS

Findings of the agglutination survey are presented in Table 3. Here also, those contributing specimens have been classified into the age groups 1-9, 10-19, 20 and above, and according to whether the "contaminated milk supply" or "other milk supplies" were used during the months preceding the epidemic. The group totalled 204; among 33 who had been exposed to contaminated milk, 12, or 36.3 per cent, showed positive agglutination for brucellosis, all in diagnostic dilutions varying from 1:80 to 1:2,560. Five children were under 10 years, the remaining 7 between 10 and 19 years of age. There was no instance of agglutination in diagnostic titer among 171 consumers of other milk supplies.

RESULTS OF SKIN TESTS

Material for performing intradermal tests with brucellergen, was supplied through the courtesy of Dr. Huddleson of Michigan State College. Two separate antigens were used without further dilution, one prepared from *Brucella abortus* (1:12,000), the other from *Brucella suis* (1:4,000). One girl of teen age whose agglutination test was negative, but who was apparently very allergic, showed a severe reaction, with subsequent necrosis of the skin and subcutaneous tissues. In a few instances, individuals showed a more marked reaction with brucellergen suis than with brucellergen abortus.

A summary of results of the series of intradermal tests is contained in Table 4. A striking difference will be noted in the percentage of positive skin tests among those using contaminated milk as compared with those whose milk came from other sources. Among 57 persons of all ages who used the contaminated milk supply, 42, 73.7 per cent, showed positive skin reactions, whereas 17, or 10.8 per cent, of 158

consumers of other milk showed a positive or an allergic response.

FOLLOW-UP OF AGGLUTINATION REACTIONS

On October 18, 1942, another blood specimen for agglutination was obtained by one of us (D.M.H.) with the coöperation of M. F. Joynt, M.D., of Marcus. Of 27 patients, whose serum showed agglutination of brucella antigen in titers from 1:160 to 1:1,280 during the late months of 1941, 7 showed negative agglutination and 16 had titers down to 1:10, 1:20, or 1:40 in October, 1942.

DIAGNOSIS, CONTROL, AND PREVENTION

The isolation of brucella from the blood stream stands first among laboratory aids which confirm the physician's clinical diagnosis of brucellosis. Finding of the organism makes possible its species identification, which in turn helps to establish the source of infection in hogs, cows, or other animals.

The presence of agglutination in diagnostic dilution is second only to the blood culture as an aid in clinical diagnosis. Both rapid and slow methods of agglutination are dependable. Should a first specimen show negative or weakly positive agglutination, taking of subsequent specimens will frequently result in strongly positive agglutination reports.

A positive intradermal test with brucella antigen signifies exposure to brucella infection in the recent or remote past. Simpson⁶ advises against over-emphasizing the diagnostic significance

of this test, stating that the intradermal test when positive "does not mean that the symptoms from which the patient is suffering at the time are necessarily due to brucellosis."

Findings of the opsonocytophagic test are probably most dependable when observed soon after onset of symptoms. Results need to be interpreted with caution.

Economically and from a health standpoint, brucellosis is one of the most important diseases transmissible from animals to man. Measures for eradication of Bang's disease need to be pursued vigorously in coöperation with veterinarians, the Federal Bureau of Animal Industry, and state departments of agriculture.

Use of none but carefully pasteurized dairy products and enforcement by cities and communities of the *Standard Milk Ordinance* as recommended by the U. S. Public Health Service, afford the best assurance against the possibility of milk-borne disease.

Some Epidemiological Aspects of Tuberculosis Determined by Analysis of Sanatorium Records*

ROY M. SEIDEMAN, M.D., DR.P.H.

District Medical Officer for Civilian Defense, New York State Health Preparedness Commission, Rochester, N. Y.

IN September, 1938, the Massachusetts State Department of Health, with the coöperation of the Middlesex County Sanatorium and the financial support of the Commonwealth Fund, called on the writer to make a statistical analysis of the clinic records of the county sanatorium. The purpose of this study was to throw more light upon the epidemiology of tuberculosis in order that methods of disease control could be better evaluated.

SOURCE OF CLINICAL MATERIAL

Middlesex County is the third largest county in Massachusetts, comprising an area of 844 square miles. The tuberculosis hospital district excludes the cities of Cambridge and Lowell. There are 43 towns and 9 cities in the hospital district, with a population of 759,122 (1940 census), of which approximately 14 per cent is foreign born. The area served by the hospital is chiefly residential, many of the white-collar workers commuting to Boston. The chief industries include textile mills, shoe manufacture, mechanical assembly plants, tanneries, oil refineries, and a large granite quarry in one small town. At the time of this

study (1938-1940) the tuberculosis mortality rate was approximately 28 per 100,000.

The study is based on a total of 10,929 patients examined in the sanatorium out-patient department during the years 1931-1938 inclusive. There were 1,220 active cases of tuberculosis diagnosed during the period, representing a gross morbidity of 11.1 per cent. These patients were referred to the sanatorium by (1) private physicians, (2) sanatorium social service because of known familial contact, (3) local boards of health because of contact with a reported case, (4) school physicians because of positive tuberculin reaction and suspicious physical findings, (5) welfare health associations because of so-called "indices" of tuberculosis, i.e., underweight, poor housing conditions, etc. In keeping with the best practices of an out-patient tuberculosis clinic, extensive records were maintained and every effort was made to examine and follow up all contacts. Each medical record includes a clinical history of the patient and his family, summary of physical examination, results of tuberculin test, x-ray interpretation, and laboratory findings.

METHOD OF STUDY

The value of a clinic group as a concentrated source of medical information

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

is acknowledged by the medical profession at large. It is admitted too that conclusions drawn from a study of a clinic population are limited because of certain inherent fallacies. That an out-patient department, functioning as an aid to diagnosis, is associated with a select group of patients is readily understood when one considers the various economic, sociological, and medical factors involved. In the present study an attempt was made to control the many variables that are known to influence the morbidity in a clinic population. For purposes of comparison strict adherence to definition was imperative.

Data on clinic records were coded, transcribed to punch cards, tabulated, and analyzed for statistical significance. Patients diagnosed "negative for tuberculosis" include persons whose chest roentgenograms were either negative or demonstrated evidence of upper lobe fibrosis and calcification, healed basal or apical pleuritis, calcified hilar glands, or the presence of a solitary parenchymal tubercle. Dependent on the subject of study, the many classifications of patients were studied singularly or grouped in broader categories. The method of grouping is defined in each of the parts of the present study.

I. STUDY OF TOTAL OUT-PATIENT POPULATION

Of the total patients examined, 5,334 gave a history of intimate contact with a case sharing the same household environment at the time of examination or at some previous time. Tuberculosis morbidity in contacts was determined in relation to the family aggregate by classification according to sex and familial relationship to source case. More comparable rates were obtained by the exclusion of patients under 15 since this age group did not include consorts. The age-adjusted morbidity rates are shown in Chart I.

The rates were obtained by the "direct method," employing the formula $\Sigma P_1 \dots k \cdot r_1 \dots k$ in which P represents the age-specific population of the total contact population examined and r the age-specific rates by sex and relationship to source case. Of note is the comparatively low rate in consorts, and the higher morbidity in females in all classifications other than patients exposed to "father."

From a review of the individual case records it was apparent that 805 contacts reporting a tuberculosis death in the family household 1 to 10 years prior to examination were examined for reasons other than contact; in the 4,529 remaining contacts, however, examination was indicated chiefly because of contact. It was believed that analysis of the latter group would yield more comparable rates since the many factors, illness particularly, associated with a clinic population were thereby minimized.

Among the 4,529 contacts there were discovered 323 cases of tuberculosis, 223 among the 2,521 females and 100 among the 2,008 males. This is a significantly higher morbidity in females.

The age-specific tuberculosis morbidity is shown in Table. 1. For comparison similar data are given for the 4,955

patients with no known exposure and who were examined for reasons other than contact. In Table 1 and Chart II-A it is noted that the morbidity in females under 50 is consistently higher than that in males of similar age. In patients with a negative history of contact (Table 1, Chart II-B), among those under 20, the morbidity is higher in females; over 20 the morbidity rate is significantly higher in males, as measured by the chi-square test for statistical significance.

The morbidity according to sex and relationship to source is summarized in Table 2. Of note is the higher morbidity in females, particularly those exposed to a "sibling" and, dependent on age, the comparatively low morbidity in consorts.

II. THE DEVELOPMENT OF TUBERCULOSIS AS OBSERVED IN THE OUT-PATIENT CLINIC

In Part I it was noted that 1,220 cases of tuberculosis were diagnosed in 10,929 patients. Of the remaining 9,709 patients 268 gave evidence of non-tuberculous pulmonary disease on x-ray, and were referred to general hospitals for therapy. There were 9,441 persons whose chest roentgenograms on initial examination were either negative or demonstrated evidence of healed spe-

cific or nonspecific pulmonary infection. This group constitutes the patients in whom the development of tuberculosis was observed. A patient who was seen to develop the disease is defined as a "breakdown."

It is obvious that a number of factors played a part in determining the frequency of reexamination and the duration of follow-up, i.e., coöperation of the patient, age, contact, tuberculin reaction, and other clinical data referable to respiratory infection. The object of this administrative procedure was to diagnose tuberculosis in its earliest stages in a clinic group which was thought highly susceptible to the disease.

Of the total negative population, 4,076 patients were observed for a period of at least 1 year. The rate of development of tuberculosis (breakdown rate) is presented in Table 3, employing a "modified life table method."¹ The duration of follow-up is expressed to the nearest year. The cumulative per cent breakdown for a period of 6-7 years of observation is $3.31 \pm .61$; 54 of the 65 breakdowns occurred within the first 2 years. This rate is based on the rate at which the patients were dropped from the clinic and is therefore adjusted for duration of follow-up. An estimate of the

standard deviation of a cumulative rate was derived by the formula $\sigma^2 = \sigma_1^2 + \sigma_2^2 + \dots + \sigma_n^2$, i.e., the (S.D.)² of the rate equals the (S.D.)² of the year-specific rates. By the same method, statistical comparison of the cumulative morbidity by sex for a like period of observation yields a higher rate in females than in males, 4.66 ± 1.1 cf $1.71 \pm .38$ per cent.

Because of the small number of breakdowns it was thought that the determination of breakdown rates according to the total number of years of observation (person-years) rather than to the total persons followed would offer a better method for comparative purposes. In this statistical procedure it is assumed that the rate of dropping-out of clinical observation is the same for the various classifications of persons (by age, sex, and contact) studied. The 4,076 patients represent a total of 9,641 person-years of observation; the rate of breakdown for the entire group being $0.68 \pm .08$ per 100 years. The age-specific rates are shown in Table 4.

The breakdown rates according to sex are summarized in Table 5. Under

20 the rate in females is almost twice that in males ($\chi^2 = 6.14$, $p = .014$); in older ages the differences between the sexes are not statistically different. Based on total number of years of observation, however, the rate in females is significantly higher than that in males.

That the risk of breakdown varies with the degree of exposure is shown in Table 6.

TABLE 6

It is of interest to compare the data in Table 4 with Table 7. In Table 7 the age-specific population may be looked upon as so many years of observation, the new cases as so many breakdowns. In this sense the data may be considered comparable with Table 4. In the age groups 0-14 and 15-19 it is of note that the rates in the

TABLE 7

New Cases of Pulmonary Tuberculosis Reported in Massachusetts in 1937

clinic population are approximately from two to two and one-half times that of the general population. These differences are statistically significant. A review of the age distribution of the two populations reveals striking differences. For this reason the morbidity rate of the clinic population was adjusted to the age distribution of the state. By so doing the rate ($.743 \pm .09$) obtained in the sanatorium group tends to approximate the rate ($.821 \pm .01$) in the general population.

III. STUDY OF COMPLETE FAMILIES

The contact data in Part I were based on family history from individual records and not related to results of examination of the entire family household. To test the validity of con-

clusions that could be drawn from Part I a more objective approach to the epidemiology of tuberculosis was made by a study of families in which all members were examined. By this method it was believed that such factors as cause for or failure of examination would be subject to better control.

This study comprises 479 families in which all living members of the household were examined either at the county sanatorium or another institution within the state. In each family there was at least 1 case of tuberculosis, and family history revealed no known death from the disease at the time of examination. These families represented 1,884 living household members. The age-specific tuberculosis morbidity is noted in Table 8.

The primary case is the member of the household with the most advanced stage of pulmonary tuberculosis; in families with more than one member with the same stage of disease, the oldest was designated as the primary case. The exact ages of 32 patients with advanced disease were unknown; approximate ages, however, were estimated by a study of their relationship to other members of the household. Columns (3) and (8) of the same table represent the number of cases (breakdowns, v.s.) diagnosed by serial x-ray examination. In 4 families (col. 3) the entire household was examined because a member was seen to develop the disease on follow-up. In these cases the reason for repeated examination was clinical, i.e., underweight, tuberculin sensitivity, and chronic respiratory ailments.

A single examination of the 1,405 contacts revealed a tuberculosis morbidity of 5.3 per cent, the rate in the 20-24 year age group being three times that of the group as a whole. In column (9) it is noted that 1.7 per cent of 1,331 contacts essentially negative on

CHART III
MORBIDITY IN CONTACTS OF COMPLETELY EXAMINED HOUSEHOLDS

initial examination were observed to develop the disease by serial roentgenography. It is significant to note that contacts 15-19 years of age revealed a morbidity on subsequent examination comparable to that on initial examination. It is to be emphasized that, in comparing the breakdown rates according to age, it is assumed that the period of observation is comparable in all age groups. The total morbidity in contacts as determined by both initial and subsequent examinations is 6.9 per cent.

Morbidity by sex is shown in Table 9 and Chart III. For the total house-

* Approximate

hold population under 30 years of age a significantly higher morbidity rate is obtained in females; above this age a higher morbidity is obtained in males. For the total contacts of primary cases a significantly higher attack rate is found in females as compared with males, i.e., 8.3 cf 5.3 per cent. These rates are similar to those obtained in the total sanatorium population exposed to living household cases, i.e., 8.8 cf 5.0 per cent (v.s. Table 1).

IV. ADDITIONAL FACTORS INFLUENCING MORBIDITY

A total of 65 breakdowns occurred in 60 families; in 5 families 2 breakdowns occurred simultaneously. Ten breakdowns showed x-ray evidence of hilar calcification. The results of the Mantoux test at the time of initial examination were as follows:

Positive to .01 mg. OT.....	49
Positive to 1 mg. OT.....	5
Negative to both doses.....	5
Negative to .01 mg. OT, 1 mg. OT not given..	5
No test	1
Total	65

Of 20 patients who had been previously tested in the Chadwick Clinics (see below), 5 were reported positive and 15 negative to the Von Pirquet test.

In order to determine with the material available what factors about the patient and family influenced morbidity subsequent to initial examination, two groups of families were compared: (1) those families referred to as "breakdown" families in which some member developed tuberculosis while

under observation, and (2) a random sample of families in which no "breakdown" was observed. Of 208 contacts of "breakdown" families, 52 had been previously tested with tuberculin in the Chadwick Clinics sometime prior to admission to the sanatorium outpatient clinic. These tests were employed routinely in the school population as a screening method in a case finding program. It is to be emphasized that the data accumulated in the Chadwick Clinics are independent of the present study. That is, the data of each patient examined in the sanatorium clinic were coded according to family group, and reference was then made to the Chadwick Clinic records to determine whether results of routine tuberculin tests according to Table 10 were available. Of the control group of families, 67 of a total of 608 contacts studied had been previously tested. The average age at the time of the school test was 11 years, and that at the time of examination in the OPD clinic 15½ years.

The tuberculin reaction in the Chadwick Clinics among these 119 individuals is presented in Table 10. The per cent infected at the time of the school test is lower in the "breakdown" families as compared with the control group; the difference is greater than would be expected by chance alone ($\chi^2 = 5.10$).

The duration of illness of the primary case (see Part III) was employed as an index of the duration of exposure of other household members. The duration of exposure was measurable in 49

TABLE 10

Total	49	100	163	100	212	100

of the 60 "breakdown" families. These families were compared with a random sample of 163 families in which no breakdown occurred. The mean duration of exposure (expressed in months) of contacts was found to be 20.53 ± 1.26 in "breakdown" families as opposed to 31.97 ± 1.22 in the "control" families. The difference is statistically significant. These results are confirmed by a comparison of whole families. It was thought that the influence of size of family on the mean duration of exposure per person was thereby eliminated. A summary of the findings as expressed in Table 11 reveals a shorter duration of contact in "breakdown" families ($\chi^2 = 4.63$, $p = .031$).

The low rate of breakdown reported in Part II might possibly be explained by the above results. Evidence of more recent infection as measured by the tuberculin test and duration of exposure is obtained in "breakdown" families when compared with families in which a breakdown was not observed. It would appear that, in clinic practice, by the time the tuberculous patient seeks medical aid all susceptible contacts have already developed the disease.

V. TUBERCULOSIS FATALITY

The prognosis as to life expectancy of all tuberculous patients was calculated as of the time of examination at the Middlesex Clinic. The method used for the accumulation of the data must necessarily be explained for proper interpretation of Table 12. The

patients were followed for a varying number of years depending on the year of diagnosis. For example, those first examined as early as 1931 could have been followed for a maximum of 8 years, whereas those first examined in 1938 could have been followed for no more than 1 year.

Of 1,212 cases of pulmonary tuberculosis diagnosed at the sanatorium clinic, 130 gave a history of previous diagnosis and treatment. The latter patients are excluded from this part of the study. Thus, the 1,082 patients included in calculating the mortality experience represent new cases, diagnosed for the first time anywhere. Although not all patients were followed in the hospital ward or clinic, data on each patient up to the time of death or time of this study were obtained through other sources of information. Thus, if a patient refused hospitalization or dropped from the clinic against advice, additional information about the patient was sought by (1) examination of state vital statistics reports for possible cause and time of death, (2) reports by health department personnel, i.e., visiting nurses associated with the state-wide reclassification clinics, and (3) reports of diagnosis obtained from general hospitals and other sanatoria. Some patients, who were known to have moved out of the state and whose whereabouts was unknown at the time of study, are included. Their number, however, is too small to affect the results. The method used for determining the case fatality rates is essentially the same as

TABLE 12

that recommended by Puffer, et al.¹ In the method employed by these authors it is assumed that the median duration of follow-up of patients dropped from observation during any one year is 6 months. In the present analysis, however, the length of follow-up is expressed to the nearest year.

The cumulative death rate shown in the last column of Table 12 is obtained by the life table method and represents the probability of death within a year. In far-advanced cases, for example, it is seen that the percentage dying of tuberculosis during the first and second years is 24.6 and 12.7 respectively. Thus, since 75.4 and 87.3 per cent survive the first and second years, the proportion of the original number (515)

who survive through 2 years is $75.4 \times 87.3 = 65.8$ per cent. The risk of dying within the first 2 years is, as shown in the last column, $100 - 65.8 = 34.2$ per cent. Similarly, the risk of dying within 6 years is 47 per cent. In minimal and moderately advanced cases the risks of dying within 6 years are 5 and 11 per cent respectively. The cumulative death rate due to other causes was derived by the formula $r = r_1 + r_2 + \dots + r_n$. This method is applicable when the rates are small.

SUMMARY AND DISCUSSION

In this study the comparative incidence of tuberculosis according to relationship of contact to exposure case re-

veals a significantly lower rate in consorts as compared with other familial contacts. Although comparative morbidity of household contacts has not been a subject of study, a review of the literature on conjugal tuberculosis reveals interesting controversial findings and conclusions. Rowland² and Gaetano³ found that tuberculosis in both husband and wife was relatively infrequent. On the other hand, a high incidence of conjugal tuberculosis is reported by Opie and McPhedran,⁴ and Spector.⁵

The discrepancy in such findings is partly explained by Sopp⁶ and Kayser-Petersen,⁷ who showed that age was an important variable to be considered in a study of comparative morbidity, the incidence of tuberculosis in consorts of younger age groups being greater than that of older age groups. Similar results were obtained with a study of records at the Henry Phipps Institute by Paterson,⁸ who also concluded that the mortality in consorts is significantly higher than would be expected among people of similar color and age in the general population of the same district. It should be noted that the present study differs from the above mentioned, in that morbidity was compared in a select group, i.e., contacts of household cases. In this specific group it is shown that the morbidity among consorts is lower than that among other household contacts.

In patients examined because of contact the morbidity rate in females is greater than that in males regardless of age and relationship of exposure cases; in patients examined for reasons other than contact the morbidity in females is greater than that in males in younger age groups, whereas the reverse is true in older age groups. In a routine roentgen survey of 12,603 inmates of the Southwestern State Hospital, Blalock, Funkhouser and Flannagan⁹ found that the incidence of x-ray evi-

dence of tuberculous disease was greater in females than males, the ratio of the attack rates being 2:1. Holm¹⁰ concluded that in Copenhagen tuberculous morbidity is equal for both sexes up to age 30, but after 30 it is more prevalent among men; in rural districts tuberculosis is more frequent in women than in men. In a report by Hutchinson and Pope¹¹ on tuberculosis among school children of 79 Massachusetts cities and towns, the morbidity rate was found greater in females than males in all ages between 5 and 15 years.

In the present study it is shown that the rate of development of tuberculosis as observed in the out-patient clinic is, on the whole, comparable to that of the general population. As in the findings on initial examination, the breakdown rate is higher in females. Families in which a member was observed to develop tuberculosis showed evidence of more recent infection as measured by the results of the tuberculin test and duration of exposure when compared with a control series of families without breakdown. Horton¹² reports from his experience in the clinics of the Homer Folks Hospital that practically all cases were found at first examination. Haywood, Morriss, and Wilson¹³ in a study of duration of contact emphasized the importance of short periods of contact, the 12 months period containing 44 per cent of manifest cases. Downes¹⁴ in a study of the tuberculosis records of Cattaraugus County found that the incidence of secondary cases among family contacts was highest within the first 2 years after exposure with a rate of 3.6 per 100 persons within the first year and 1.6 within the second year after exposure to familial tuberculosis, the attack rate remaining at a low level after the second year. It would appear from such findings and those of this report that most of the cases of tuberculosis have developed before an indication for examination for

tuberculosis has been called to the attention of the clinic.

Pope, Sartwell, and Zacks,¹⁵ in reporting the cumulative morbidity in children as observed in the Chadwick Clinics, estimated a rate of 3.19 per 100 after 7-8 years of observation, as opposed to 3.31 per 100 found in this study. The rate of breakdown by sex during the same period of observation as reported by the above authors was 1.72 for males and 4.41 for females. These rates are markedly similar to the results of the present study, i.e., 1.71 for males and 4.66 for females.

In the present study of 479 complete families, the tuberculous morbidity rate in contacts is shown to be 6.9 per cent. Jessel¹⁶ reported a rate of 7.5 per cent in Lancashire. Similarly, Turner in Worcestershire¹⁷ reported a rate of 8.2 per cent in contacts of tuberculous families. In this country, Haywood, Morriss, and Wilson¹³ determined a morbidity rate in contacts of 8.4 per cent in a study of 156 families examined at the Gaylord Farm Sanatorium in Connecticut.

The survival time according to stage of disease is presented. The case fatality rates for the period of 6 years after initial examination are: minimal, 5 per cent, moderately advanced, 11 per cent, far-advanced, 48 per cent.

Numerous studies on death rates of tuberculosis patients following admission or discharge from sanatoria have been published since the literature was reviewed by Hilleboe¹⁸ and Brieger.¹⁹ Puffer, Stewart, and Gass^{20, 21} reported on the mortality rates of cases of tuberculosis observed in Williamson County, Tenn., in which hospitalization facilities were not available. The mortality of tuberculous cases within 4 years following first classification was 73.1 per cent of far-advanced cases and 40.9 per cent of moderately advanced cases, as opposed to 43.7 and 7.3 per cent in the present study.

Hilleboe (v.s.), using the basic data from Brompton Hospital, England, for the years 1905-1914, estimated the percentage dead 5 years after discharge from the hospital as follows: far-advanced 79, moderately advanced 40, minimal 10. The same author²² in presenting statistics on death rates of patients discharged from public sanatoria in Minnesota during the years 1926-1935, reported the following rates for the period of 6 years after discharge: minimal negative-sputum group, 3.6 per cent; moderately advanced group, positive sputum, 11.4 per cent; far-advanced group, positive sputum, 74.6 per cent, and negative sputum 20.9 per cent.

Gauld, et al.²³ analyzed the data on all persons discharged from the various tuberculosis sanatoria of Maryland during the years 1934-1938. Of far-advanced cases 29 per cent were dead 1 year after discharge, and 62 per cent at the end of 5 years. The mortality of those patients with moderately advanced lesions was 7 per cent within a year and 25 per cent within 5 years after discharge. Of the minimal cases, 1.5 per cent died within 1 year and approximately 6 per cent within 5 years. It is apparent to the reader that the various studies including the present report are not strictly comparable in the sense that adjustment for such factors as age, sex, and sputum findings is necessary for comparative purposes.

CONCLUSIONS

From a statistical viewpoint the behavior of tuberculosis can best be studied in an unselected group. However, the following conclusions are drawn from a study of the records of a county tuberculosis sanatorium:

1. If age and sex are kept constant the attack rate among consorts is lower than that among other household contacts.
2. Females are more susceptible to tuberculosis than males.

3. Practically all cases of tuberculosis are diagnosed on single examination; the rate of development of tuberculosis in patients negative on initial examination is the same as that of the general population.

4. A study of 479 completely examined households with at least one living case of tuberculosis reveals a total morbidity of approximately 7 per cent in contacts. Of the total examined, the morbidity rate is higher in females than males up to the age of 30 years; in contacts of primary cases the morbidity rate in females exceeds that of males in all ages.

5. The survival time of tuberculous patients is presented. The case fatality rates for 6 years following initial examination are: minimal, 5 per cent; moderately advanced, 11 per cent; far advanced, 48 per cent.

Effect of War Upon the Minds of Children*

BERT I. BEVERLY, M.D.

Assistant Clinical Professor of Pediatrics, University of Illinois, Chicago, Ill.

THERE are several reasons why we emphasize children's programs during war. The chief reason is that children are one of the important reasons for fighting for the preservation of our country and our way of life. We are most concerned about them and their heritage.

Since the environmental factors which determine mental health or mental ill health have been established, one method of approach to the question: "What is the effect of war upon the minds of children?" is to describe briefly the environmental conditions which promote mental health and then to apply those general principles to war situations.

ESSENTIALS FOR MENTAL HEALTH

The essentials for mental health are: security and an opportunity to grow according to individual patterns. The child then develops the self confidence which leads to the acquisition of habits of responsibility and of self reliance which in turn gives him the courage to face the problem of life and make a successful adjustment in society.

The first essential for mental health is *security*. This is the feeling which is given a child from birth by parents who wanted a child and who accept him as he is, no alterations being necessary. Since the younger the child

the greater this particular emotional need, most security is given by parents or parent substitutes. For the older child there is need for security from the family, the school, the community, and the nation. As indicated above, from this security boys and girls develop the self confidence that leads to self reliance in adulthood.

The second essential for mental health is to let children grow up according to their individual patterns. In order to do this, it is necessary for parents, teachers, and others to recognize the innate potentialities for growth and development in children, to determine children's individual differences, and learn what is normal for each age. Standards of behavior adapted to the age and capacity of the individual child permit a maximum growth. Environmental expectations which are beyond the youngster's grasp create confusion which results in fear and resentment. With this short description of basic principles, let us consider the influence of war upon mental health.

WAR AND MENTAL HEALTH

Since security is given largely by parents (especially in young children), their attitude and, therefore, the attitude of adults toward war is of great importance. This brings up the whole question of morale. There is no doubt but that children can "take it" if their parents can. In this connection, the first thing for all of us to do is to face the situation and admit that we are

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

somewhat scared. That is nothing of which we should be ashamed. The uncertainties which surround most families together with the real dangers to which some of them will be exposed are normal stimulants of fear. Actually to be a little scared is good for it stimulates activity and, with its close ally resentment, promotes determination.

Every family should appraise the situation in which it finds itself. The aim of every individual should be directed toward the national aims and the support of the government in its determined efforts. Submission to authority is good for civilian as well as for military morale. The lessening of individual competition and the coöperation of all working together gives everyone satisfaction. On the other hand, the expression of hates which are not permissible during peacetime contributes to a lowering of personal morale during war. When individuals and families have determined the probable rôle they are to play in the war, they should make plans to meet it. The changes which may take place within the family and community should be discussed with the children in order that they may decide how to meet the eventualities as and if they arise. Children who are old enough to understand can get a great deal of benefit as well as satisfaction out of helping to devise such a program. Every member of the family should have a part to play. Having worked out procedures for possible changes in the family routine and emergencies, the children as well as the parents should carry on as nearly as possible their regular routine. It should be kept constantly in mind that children imitate their parents.

AGE DIFFERENCES

The effect of war upon children depends upon the age of the child. Even

infants from birth are disturbed by anxieties of parents. The effect upon the young baby of apprehension in the mother is observed frequently by every physician.

Preschool children are most frightened by separation from their parents. In England, for example, they have shown the greatest anxiety when they were separated from their parents during blackouts. Small children have no conception of war. To them Hitler is analogous to the "bogeyman" and other supernatural symbols. Their mental health depends upon the security they feel in their parents and home. When father is out of the home for long hours because of work or being away from home, their security depends upon mother's ability to take charge and make them feel that everything is all right. Those mothers whom I have observed are doing a remarkably fine job of managing their families without the aid of their husbands.

PROBLEMS IN DEFENSE INDUSTRIAL AREAS

There are a great many disruptions of homes, however, which are causing serious harm to the physical and mental health of children. I refer to those families in which fathers are away and the mothers are working in war factories. The children of all ages are left home without adequate supervision or general care. Mothers go home after 8 hours of work, 6 days a week, and often do the family washing and heavy housework. They are tired, and often cannot help being irritable toward their children. The extent of the problem is illustrated by one war plant in the middle west which employs about 1,400 women. This plant runs three shifts, 7 days a week, each employee having one day off each week. Fifty per cent of these workers are married women and a great many have from one to seven children. They have been found

to be reliable, efficient employees except that they often become fatigued and have to leave or must quit because they can find no one to keep track of their children—not to mention the care of them. These women live in all parts of the city. There are insufficient nursery schools—and those open but 6 days a week when the factory runs 7—to care for those who work on the day shift, and no means has been devised to help those who work on the afternoon and night shifts. There has been a considerable amount of discussion of this problem but there has been no relief to the children of these workers. Unless immediate measures are taken to give them supervision and care, we can prognosticate serious physical and mental ill health for them.

The rapid growth of war factories in small towns and out in the country has created another situation which threatens the health (both physical and mental) of the children of employees in those plants. The population of many villages has increased so rapidly that the health, sanitary, recreational, and school facilities are wholly inadequate to take care of the increased load, and the communities are not financially able to meet the situation. Trailer camps and make-shift villages which have experienced a mushroom growth create other problems. Here, too, mothers often work, leaving their children to shift for themselves. Unless some means are made for providing facilities for the care of these children, we can confidently expect epidemics and mental ill health among them.

Children of school age retain their anxieties of previous years but are old enough to have a concrete conception of war. They think more about bombings and what may happen to them. Possible loss of home, less food and clothing, are of real concern to them. They are afraid that father who is in the army may be killed.

During the ages of 9 to 13 years there are fewer serious anxieties, according to the experience of the British, than in younger or older children. During this period youngsters like to dramatize events in life and thereby act out their feelings. In this way, a part of their tension is relieved. Although they are scared, the idea of war appeals to them.

The adolescents carry the anxieties of childhood together with the problems peculiar to their age. Everyone will agree that the hardships of war fall heavily upon youth. They are expected to grow up more rapidly, often assume responsibilities beyond their level of growth; their education, vocation, marriage and start in life must be postponed for an indefinite period. This change is not entirely on the red side of the ledger, however. For those adolescents who are sufficiently mature, the war situation offers an opportunity to develop their abilities and make a more successful adjustment than during peacetimes. Nearly all of them, however, are faced with attitudes both within and without the home, which are opposite to the kind they faced during childhood. I refer to the fact that for twenty-five years we have been teaching our children that war is wrong and other fairy book stories which are contrary to the hard facts of life. Their ability to adjust successfully to our rapidly changing philosophy of life is one reason for saying that democracy works and is a glowing tribute to American parents and youth.

Uncertainty always stimulates anxiety. Youths hear would-be prophets predict national bankruptcy, depression, and the end of opportunity in America. These reports are disturbing and contribute to undesirable propaganda and lowered morale. As they grow up, children and youth need security in their community, church, and nation. The pessimistic remarks,

especially of those in high places make far-reaching impressions on their minds.

CHANGES IN BEHAVIOR

Having briefly described some of the conditions which surround children at the present time, and indicated the reasons for anxieties stimulated by war, we are next interested in the behavior changes which may be expected. They vary with the age of the child. Infants respond to restlessness, crying, and unhappiness. Preschool children may become negativistic and evasive, may stammer, have enuresis, and night terrors or they may become irritable and disobedient. I saw a 4 year old girl recently who developed a poor appetite and became very disobedient after her mother returned from visiting the little girl's father who was in the army. School children may react to their anxieties by expressing their fears and demanding frequent reassurance. Other signs of their insecurities may be poor school work, compulsive stealing and vandalism. Sometimes insecure, frightened children become tyrants at home and are examples of the popular misconception of "spoiled children." Adolescents react to their symptoms by neurotic complaints such as abdominal distress, rapid heart rate and weakness, or by truancy and delinquency, the most serious being sex delinquency.

SPECIFIC MEANS OF HELPING CHILDREN

I have already indicated the general measures which may be taken to minimize the effects of war upon the minds of children. Let us now consider some of the specific means of aiding them. Adults and children can be given a great deal of help and their anxieties can be lessened by adjusting their emotional needs to the conditions of war. The wave of determination to devote our all-out efforts to win this war, and the certainty in our minds that it will be won, together with the

unity of effort which has developed in the last 10 months, has done much to improve general and individual morale and lessen anxieties in adults.

With higher parental morale the morale of children is increased. Young children can be relieved of anxieties in proportion to the security they feel in their parents. Every effort should be made to keep them with their parents. It is especially important during black-outs because they feel safe only when they are very close to them. When father is out of the home, mother can give adequate security if a well organized and well thought-out plan is made wherein everyone knows what to do in case of emergency, and if the children are made to feel that their mother will be there to see that everything is all right.

Children can get a great deal of satisfaction out of developing a plan for an air raid shelter and they learn how to play and do things together as well as indulge in constructive play which aims to help others when they help in the preparation of a bomb shelter. In the absence of both parents children can be made to feel secure by a mother substitute who is capable and who knows exactly what to do in case of an emergency.

"If you want to encourage a child to be brave," says Glover in a recent book, "you do not begin by telling him that he is silly; you encourage his sense of responsibility, give him something sensible and useful to do, show him a good example, tell him the truth, admit your errors and be friendly with him. He will do the rest himself." It is better not to indulge in a large number of drills; children do best if given a few simple directions and enough responsibility to feel that they play an important part in meeting an emergency.

Children of school age get additional relief from anxiety through free expression of thought in play. They can-

not be kept from hearing war news, and enjoy it too much to be deprived of it even if it were possible to do so. Parents, therefore, should discuss the war with them, help them to reject malicious propaganda and unfounded rumors, and assure them that the outcome will be victory for us. It is a good time to let them develop pride in our country and assurance of a better future. War games provide an excellent emotional outlet and should be encouraged. Boys and girls like to feel important and to believe they are a part of the victory program. This expression may be fostered by buying stamps, collecting scrap, messenger work, and helping the Red Cross. It is important for them to do these things only during their spare time and while the home is running on as near to a normal schedule as possible. Surely, there is no reason for shortening the school year or dispensing with any part of the curriculum.

PROBLEMS OF ADOLESCENTS

The adolescent may be given moral support and helped by giving him emotional outlets in terms of his emotional needs. At this age, boys and girls require security in their parents, their homes, the community, the church, and the nation, as well as praise for their efforts and opportunity compatible with their abilities and degree of emotional maturity.

Young men and women should feel that there is something they can do well, that there is a place in society for them now and that there will be an important place for them after the war is won. Since the military services cannot give every individual an opportunity to develop his particular abilities, it is important that there should be opportunities for them when they return to civilian life. When their emotional needs (feeling of expertness and knowledge of their importance) are

supplied, young people develop the self confidence that gives them the courage to meet difficult situations and make an adjustment to them.

The importance of training young men and young women is especially great in the mechanized warfare of the present time. Educational facilities for both vocational and professional training are useful for mental health as well as for the war effort. As a part of their training youths can be made to realize that they are not only important to their country, but that they are an important part of their country. American history, if properly taught, paves the way for the development and rationalization of love of country, and greater security by realizing more fully that this is *my* country and that there is an important place in it for *me*. American history could not be revised to conform more closely to the interests and emotional needs of the adolescent mind.

To young men and women, independence and adventure are of utmost importance. It should be pointed out to them that it was rebels who, seeking opportunity and adventure, founded and developed this country. They should be brought to recognize that their first ancestors in this country, whether they came over one or ten generations ago, felt the same way about life that they feel today. They can be made to feel that the days of adventure will not be over after the war. The land frontier, it is true, is gone, but the frontiers of science, with the possibilities of invention which are just beginning to be recognized, offer far greater opportunities for progress in the future than our forefathers dreamed possible.

Adolescents can be made to understand that this is the best country in the world for the expression of independence, opportunities for adventure, and real hope for achievement. The

basic principle of democracy is that individuals are important and each one has a voice in government, business and social life. In these ways young people can identify themselves with the past and be assured of the future, even though economic conditions may be serious. The war will only temporarily interfere with their life program. In the near future they will inherit the country because they will take their parents' place in the world. This, then, becomes *their* home and *their* country. And when they take over we can rest assured that they will do as good a job as we have done.

We can be of further help to youth by resisting the demoralizing propaganda of those depressed and dis-

couraged individuals who not only see the end of opportunity in this country but also the destruction of civilization and nothing to live for if our wealth is conscripted.

Finally, well developed and intelligently controlled and properly coördinated youth organizations are of great help. Recreational centers, scout troops, church groups, Y.M.C.A. and Y.W.C.A. schools, any well managed organization that gives boys and girls and young men and women wholesome emotional outlets and constructive social activities will prevent personal and moral deterioration that is threatened by war. There is a pressing need for coördinated youth programs in every community.

Losses of Vitamins Which May Occur During the Cooking of Dehydrated Vegetables^{*†}

FAITH FENTON, PH.D., AND BARBARA BARNES

New York State College of Home Economics, Cornell University, Ithaca, N. Y.

AND

J. C. MOYER, PH.D., KATHERINE A. WHEELER, AND
D. K. TRESSLER, PH.D., F.A.P.H.A.**

State Agricultural Experiment Station, Geneva, N. Y.

BECAUSE dehydrated vegetables are now being used in large amounts by our armed forces and in increasing amounts by civilians at home and abroad, it is important to know the nutritive value of these vegetables at the time they are actually consumed. Directions given at present for cooking dehydrated vegetables vary from starting them in cold water to starting them in boiling water; from no refreshing ‡ to refreshing them overnight, and from cooking them in small amounts of water to cooking them in as large amounts as 8 quarts of water to 1 pound of vegetable.

The work reported in this paper was part of a study of the nutritive value and palatability of dehydrated vegetables carried out coöperatively with the U. S. Bureau of Home Economics,

the University of California, and the University of Texas. The purpose of the particular study herein presented was to determine some of the factors which affect the losses of vitamins from commercially dehydrated vegetables during cooking procedures. Four commercially dehydrated vegetables—beets, cabbage, potatoes, and rutabagas—were cooked in family and in quantity amounts.

In cooking family amounts the object was to determine losses (1) of thiamin when the vegetables were (a) started in boiling water (98° C.) and started in cold water (20° C.), (b) cooked without and with refreshing, and (c) cooked in varying amounts of water; (2) of ascorbic acid from the cabbage when it was (a) put in boiling water (98° C.), and in cold water (20° C.), (b) cooked without and with refreshing, and (c) cooked in varying amounts of water; (3) of carotene from commercially dehydrated rutabagas cooked in varying amounts of water.

In cooking quantity amounts the object was to determine the losses of thiamin during steaming. Because it is common procedure to "hold" such

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

† The work reported in this paper was supported in part by the U. S. Bureau of Home Economics, Washington, D. C.

‡ "Refreshing" is the term generally applied to the preliminary soaking of dehydrated products.

** Present address, General Electric Co., Bridgeport, Conn.

vegetables before serving them, the losses of thiamin due to holding the steamed vegetables for 1 hour in a steam-heated warming oven were determined.

METHOD

History of vegetables—The history of these vegetables as well as the losses of thiamin, carotene, and ascorbic acid from them during dehydration and storage are reported by Moyer, Wheeler, and Tressler.¹

Family cookery procedures—Each vegetable was cooked in 50 gm. lots. This amount gave 4 to 5 servings. Covered, straight-sided 1 qt. enamel pans were used. The pans had a diameter of 5 in. and a depth of 3½ in. The rate of evaporation was controlled by a manometer which was placed between the gas outlet and the stove.² In each case the vegetable was brought quickly to the boiling point, and then boiled gently. Gentle boiling, or simmering, gave a more desirable texture in the cooked product than did rapid boiling.

To determine the effect of the initial temperature of the water on losses of thiamin, each vegetable was put into water at 20° C., and at 98° C., and was cooked with no preliminary soaking (Table 1). To determine the effect of refreshing, each vegetable was cooked with no preliminary soaking, and cabbage, potatoes, and rutabagas were cooked after preliminary soaking (Table 2). To determine the effect of using various amounts of water, all the vegetables were cooked in minimum amounts of water with not more than 80 gm. of water left at the end of the cooking periods, and in larger amounts of water (Table 3).

Cabbage was the only one of the four dehydrated vegetables which contained sufficient ascorbic acid for study. It was cooked with the above variables (Tables 4, 5, and 6) and the effect on

the ascorbic acid content of the cabbage was determined.

Rutabagas were the only vegetable in the group which contained sufficient carotene for study. The effect of varying the amount of water (Table 7) on the retention of carotene was determined. Because the carotene content decreased quite rapidly during storage, it was not possible to determine the effect of the other cookery variables on its retention.

*Quantity cookery procedures*¹—The dehydrated vegetables were steamed in 454 gm. lots. This amount gave 12 cups of beets, 28 cups of cabbage, 12 cups of potatoes and 20 cups of rutabagas. The losses occurring with these amounts were considered indicative of those which might occur in certain quantity procedures.

The vegetables were put in aluminum pans having a depth of 5½ in., a bottom diameter of 10½ in., and a top diameter of 13 in. The amounts of boiling water (Table 8) added to each vegetable were such that they resulted in a product of good texture and practically all of the cooking water was absorbed at the end of the "holding" period.

The pans of vegetables were placed in a standard type free-venting commercial steamer operating with live steam introduced directly into the cooking chamber. The steaming times are given in Table 8.

"Holding" of quantity steamed vegetables—The steamed vegetables were transferred in 454 gm. lots with a proportionate amount of cooking water to aluminum pans having a depth of 7 in., a diameter of 4½ in., and a capacity of 1¾ qts. They were then placed in an institutional steam-heated warming oven where they were held for 1 hour.

Vitamin determinations—The thiamin determinations were made by the method recommended for cereals by the

Research Corporation Committee on the Thiochrome Method³ as adapted for vegetables by Moyer and Tressler.⁴ The ascorbic acid determinations were made by the Bessey and King⁵ method as modified by Mack and Tressler⁶ and further modified by the use of the Waring Blendor for grinding the samples. The carotene determinations were made by the method of Zimmerman, Tressler, and Maynard.⁷

RESULTS

At the time of testing the uncooked dehydrated beets contained 1.7 micrograms of thiamin per gm., the potatoes 4.3 μ g. and the cabbage and rutabagas 5.3 μ g. per gm.

COOKING IN FAMILY QUANTITY

(1) THIAMIN LOSSES

The initial temperature of the cooking water made no appreciable difference in the per cent of thiamin retained (Table 1) except in the case of the potatoes. The differences, with this exception, were within experimental error, as were also the apparent increases in the thiamin content. Very little difference was observable in the

per cent solution of thiamin; probably no destruction of thiamin took place.

When the vegetables were put in cold water it required from 3½ to 5 minutes for the water to come to the boil (Table 1); when they were put in boiling water, the water did not stop boiling.

Refreshing—Whether the cabbage, potatoes, and rutabagas were cooked without first refreshing them or after 30 minutes of refreshing (in the case of cabbage, 60 minute refreshing) in water at 20° C. made no appreciable difference in the retention of thiamin in the cooked vegetable (Table 2). The smaller percentage retention in the cooked potatoes than that in the other vegetables and the larger loss to the cooking water were probably due to the larger amount of water used, 550 gm. for potatoes against 400 gm. for cabbage and 300 gm. for rutabagas. There was probably no destruction of thiamin.

Amount of cooking water—As shown in Table 3, with each increase in the amount of cooking water more thiamin was dissolved from each of the four vegetables into the cooking water. By doubling the amount of water in cook-

TABLE 1

Effect of Varying the Initial Temperature of Cooking Water on the Thiamin Content of Four Dehydrated Vegetables¹

	700	5.09	0.43	255	133	103	52	41

¹ Each vegetable was cooked in 50 gm. lots with no refreshing.

Temperature of the water: beets, potatoes, and rutabagas, 20° C., cabbage, 98° C.

² Too little water to analyze (6 gm.).³ This figure includes the thiamin in the cooking water which was not analyzed and that destroyed.

ing beets the retention of thiamin was decreased from 78 per cent to 53 per cent, and the solution of thiamin was increased from 20 per cent to 57 per cent. In cooking cabbage, by increasing the amount of water from 400 gm. to 700 gm., the retention of thiamin was decreased from 85 to 52 per cent. In cooking potatoes, by increasing the amount of water from 200 gm. to 300 and then to 550 gm., the retention of thiamin was decreased from 104 per cent to 75 per cent and 47 per cent, respectively, and the solution to the

cooking water was increased from 22 per cent with 300 gm. of water to 50 per cent with 550 gm. of water. In cooking rutabagas, by increasing the amount of water from 300 gm. to 550 gm., the retention of thiamin was decreased from 86 per cent to 52 per cent and the percentage dissolved was increased from less than 14 to 41 per cent.

(2) ASCORBIC ACID LOSSES FROM CABBAGE

Initial temperature of cooking water

—The uncooked dehydrated cabbage

TABLE 4

Effect of Increasing the Initial Temperature of the Cooking Water on the Ascorbic Acid Content of Dehydrated Cabbage¹

Temperature of Water	Ascorbic Acid							
	Per gm. of Cabbage		Total			Retention in Cabbage per cent	Dissolved in Cooking Water per cent	Change per cent
	Uncooked mg.	Cooked mg.	Uncooked Cabbage mg.	Cooked Cabbage mg.	Cooking Water mg.			
20°	4.1	0.17	205	56.7	25.0	28	12	-60
98°	4.1	0.42	205	145.3	35.9	71	18	-11

¹ The cabbage was not blanched previous to dehydration.

It was cooked in 50 gm. lots in 400 gm. water without refreshing, 10 minutes.

contained about 4 mg. of ascorbic acid per gm. When the cabbage was started to cook in boiling water rather than in cold, the retention of ascorbic acid was increased from 28 to 71 per cent (Table 4). When cold water was used, 60 per cent of the ascorbic acid was destroyed, 28 per cent remained in the cabbage. When boiling water was used only 11 per cent of the ascorbic acid was lost and 71 per cent was left in the cabbage. The cabbage has not been blanched to inactivate the enzymes before dehydration. Since it took longer to bring the cabbage and cold water to the boiling point, the enzyme system which oxidizes ascorbic acid had a longer time to act than when boiling water was used. There was very little difference at the two temperatures in the per cent found in the cooking water.

Refreshing—When the cabbage was cooked without refreshing, with 30 minutes refreshing and with 60 minutes refreshing in water at 20° C., the retention of ascorbic acid was 28 per cent, 19 per cent, and 17 per cent, respectively, and the destruction was 60 per cent, 78 per cent and 90 per cent respectively (Table 5). As noted in Table 2, the retention would have been relatively greater and the destruction relatively less if the cabbage had been put in boiling water. It is probable that some of the dissolved ascorbic acid was also destroyed upon standing, because the per cent of ascorbic acid in the cooking water decreased with the length of the refreshing period.

Amount of cooking water—With an increase of cooking water from 400 gm. to 700 gm. the retention of ascorbic acid in the cabbage was de-

TABLE 5

¹ The cabbage was not blanched previous to dehydration.

It was cooked in 50 gm. lots in 400 gm. water.

² Cooked 10 minutes.

³ Cooked 8 minutes.

TABLE 6

Effect of Increasing the Amount of Cooking Water on the Ascorbic Acid Content of Dehydrated Cabbage¹

Amount of Cooking Water	Ascorbic Acid							
	Per gm. of Cabbage		Total			Retention in Cabbage	Dissolved in Cooking Water	Change
	Uncooked	Cooked	Uncooked Cabbage	Cooked Cabbage	Cooking Water			
gm.	mg.	mg.	mg.	mg.	mg.	per cent	per cent	per cent
400	4.1	0.42	205	145.3	35.9	71	18	-11
700	4.1	0.26	205	96.5	87.1	47	42	-11

¹ The unblanched dehydrated cabbage was placed directly in boiling water and cooked 10 minutes with no refreshing.

TABLE 7

Effect of Increasing the Amount of Cooking Water on the Carotene Content of Dehydrated Rutabagas²

Amount of Cooking Water	Carotene				
	Per gm. of Rutabagas		Total		Retention in Rutabagas
	Uncooked	Cooked	Uncooked	Cooked	
gm.	microgram	microgram	microgram	microgram	per cent
300	13.5	2.22	675	664	98
550	13.5	1.66	675	534	79

² Fifty gm. lots of the rutabagas were placed in cold water and cooked 30 minutes with no refreshing.

² Total carotenoids.

creased from 71 per cent to 47 per cent and the solution was increased from 18 per cent to 42 per cent (Table 6). The destruction was the same in each case, 11 per cent. A similar effect of increasing the amount of cooking water on ascorbic acid retention has been reported for frozen peas, spinach, cauliflower, brussels sprouts, and lima beans,⁸ and for frozen broccoli.⁹

(3) CAROTENE IN RUTABAGAS

The uncooked dehydrated rutabagas at the time of testing contained 13.5 μ g. of carotene * per gm.

Amount of cooking water—Increasing the amount of cooking water from 300 gm. to 550 gm. decreased the retention of carotene in the rutabagas from 98 per cent to 79 per cent (Table 7). The carotene content of the rutabagas cooked in 300 gm. and in 550 gm. of water was 2.22 μ g. and 1.66 μ g. per

gm., respectively. Although carotene is relatively insoluble in water, the pieces of dehydrated vegetable were so small that it is possible that some of the carotene was dispersed in the water. The cooking water was used for the thiamin analyses and there was not sufficient for carotene analyses also.

QUANTITY COOKERY PROCEDURES

Steaming—The retention of thiamin during steaming was: beets 82 per cent, cabbage 88 per cent, potatoes 87 per cent, and rutabagas 74 per cent (Table 8). The remainder of the thiamin was dissolved in the small amount of water present. The thiamin content of the steamed vegetables was: beets, 0.34 μ g. per gm. of vegetable, cabbage, 0.64 μ g., potatoes 0.79 μ g., and rutabagas 0.68 μ g. (Table 8). The steamed beets and cabbage contained about the same amount of thiamin per gm. as they did when boiled in 50 gm. lots after being placed directly in boil-

* Total carotenoids

TABLE 8

Retention of Thiamin in Certain Dehydrated Vegetables during Steaming in Quantity¹

Vegetable	Thiamin							
	Per Gram of Vegetable		Total			Retention in Vegetable	Dissolved in Cooking Water	Change
	Uncooked	Cooked	Uncooked Vegetable	Cooked Vegetable	Cooking Water			
	microgram	microgram	microgram	microgram	microgram	per cent	per cent	per cent
Beets	1.6	0.34	726	595	85	82	11	-7
Cabbage	4.63	0.64	2,102	1,848	572	88	27	+15
Potatoes	4.34	0.79	1,970	1,719	322	87	17	+4
Rutabagas	5.46	0.68	2,479	1,832	589	74	24	-2

¹ Boiling water was added to 454 gm. of dehydrated vegetables.

Amount of water: beets, 2,006 gm.; cabbage, 3,776 gm.; potatoes, 2,360 gm.; and rutabagas, 3,304 gm.

Time of cooking: beets, 25 minutes; cabbage, 10; potatoes, 15; and rutabagas, 45 minutes.

ing water with no refreshing. In the latter study the thiamin content was beets, 0.33 μg . per gm., of vegetable and cabbage 0.63 μg . The steamed potatoes contained slightly less, and the rutabagas more than in the family quantity study.

were by the best method of boiling in family amounts, that is, placed directly in boiling water and cooked without refreshing. Steaming was not a satisfactory method for cooking the cabbage and rutabagas from the standpoint of flavor and odor.

TABLE 9

Retention of Thiamin in Certain Quantity Steamed Dehydrated Vegetables during Holding One Hour in a Steam-heated Warming Oven¹

Vegetable	Thiamin							
	Per gm. of Vegetable			Total			Retention during Holding ²	Change during Holding
	Before Holding		After Holding ²	Before Holding		After Holding ²		
	Vegetable	Cooking Water	Vegetable	Vegetable	Cooking Water	Vegetable	per cent	per cent
	microgram	microgram	microgram	microgram	microgram	microgram		
Beets	0.34	0.16	0.34	154	14	176	105	+5
Cabbage	0.64	0.53	0.62	288	53	341	98	-2
Rutabagas	0.66	0.64	0.64	304	65	338	90	-8

¹ The cooked vegetables in 454 gm. lots were held in pans in an institutional steam-heated warming oven.² Practically all of the cooking water was absorbed by the vegetables during holding.

Holding—When the steamed beets, cabbage, and rutabagas were held 1 hour in an institutional steam-heated warming oven they absorbed practically all of the cooking water. There was no appreciable loss of thiamin during the holding. The percentage changes (Table 9) were within experimental error.

Palatability—The vegetables were judged for appearance, color, odor, flavor, and consistency. The beets were judged excellent in all respects, the potatoes were rated as high as they

SUMMARY

1. The uncooked, commercially dehydrated beets contained 1.7 micrograms of thiamin per gm., on the dry basis, the potatoes 4.3 μg ., and the cabbage and rutabagas 5.3.

2. Increasing the initial temperature of the cooking water from 20° to 98° C. made no appreciable difference in the percentage of thiamin retained in the vegetable, dissolved in the cooking water, or destroyed.

3. Cooking the vegetables without refreshing, or after 30 minutes of refreshing, and also in the case of cabbage after 60 minutes of refreshing, made no appreciable difference in the percentage of thiamin retained in the vegetable, dissolved in the cooking water, or destroyed.

4. An increase in the amount of cooking water from the minimum for each vegetable caused a very marked and consistent decrease in the amount of thiamin retained in each vegetable, and an increase in the amount dissolved in the cooking water. By doubling the amount of water in cooking beets the retention of thiamin was decreased from 78 per cent to 53 per cent, and the solution of thiamin was increased from 20 per cent to 57 per cent. By increasing the amount of water in cooking cabbage from 400 gm. to 700 gm., the retention of thiamin was decreased from 85 per cent to 52 per cent. By increasing the amount of water in cooking potatoes from 200 gm. to 300 gm., and then to 550 gm., the retention of thiamin was decreased from 104 per cent to 75 per cent and 47 per cent respectively, and the solution to the cooking water was increased from 22 per cent with 300 gm. of water to 50 per cent with 550 gm. of water. By increasing the amount of water from 300 gm. to 550 gm. in cooking rutabagas the retention of thiamin was decreased from 86 per cent to 52 per cent and the percentage solution was increased from less than 14 to 41 per cent. There was no destruction of thiamin in any case as the changes were within experimental error.

5. The uncooked, dehydrated cabbage contained about 4 gm. of ascorbic acid per gm. on the dry basis.

6. Increasing the initial temperature of the cooking water for the unblanched, dehydrated cabbage from 20° to 98° C. caused an increase in the retention of ascorbic acid in the cabbage from 28 per cent to 71 per cent, and a decrease in the destruction of ascorbic acid from 60 per cent to 11 per cent.

7. When the cabbage was cooked without refreshing, after 30 minutes of refreshing and after 60 minutes of refreshing, the retention of ascorbic acid in the cabbage was 28 per cent, 19 per cent, and 7 per cent, respectively; the destruction was 60 per cent, 78 per cent, and 90 per cent, respectively, and the solution was 12 per cent, 6 per cent, and 3 per cent, respectively.

8. When the amount of cooking water for cabbage was increased from 400 gm. to 700 gm. the retention of ascorbic acid in the cabbage was decreased from 71 per cent to 47 per cent. The solution was increased from 18 per cent to 42 per cent, and the destruction, 11 per cent, was the same.

9. When the amount of cooking water for rutabagas was increased from 400 gm. to 700

gm. the retention of carotene was decreased from 98 per cent to 79 per cent.

10. When steamed in quantity, commercially dehydrated beets, cabbage, potatoes, and rutabagas retained 82 per cent of their thiamin, 88 per cent, 87 per cent, and 74 per cent respectively. The remainder of the thiamin was found in the small amount of cooking water present. At the end of the "holding" period this water was absorbed by the vegetables.

11. When steamed in quantity, commercially dehydrated beets, cabbage, potatoes, and rutabagas contained 0.34 μ g. of thiamin per gm., 0.64 μ g., 0.79 μ g., and 0.68 μ g., respectively. For beets and cabbage the amount is about the same as when they were placed in a small amount of boiling water and cooked without refreshing.

12. The steamed vegetables lost no appreciable amount of thiamin upon being held in a warming oven for 1 hour. Practically all of the cooking water was absorbed.

13. Steaming was a very satisfactory method for quantity cooking of dehydrated beets and potatoes from the palatability standpoint. It was not satisfactory for the so-called strong juiced vegetables, cabbage, and rutabagas.

Epidemiology of Plague in Ecuador*

ATILIO MACCHIAVELLO, M.D., DR.P.H., F.A.P.H.A.

Director, National Institute of Hygiene, Guayaquil, Ecuador

BUBONIC plague made its entry into Ecuador through the port of Guayaquil in 1908, the official announcement of its presence being made March 7. Eskey and Miño believe that the infection came from some Peruvian port, but Long suggests, as in the case of Antofagasta, that it may have originated in plague fleas brought from India in cargoes of jute bags.

From 1908 to 1930, plague appeared annually, from December to May, that is, during the warm, rainy season known locally as winter. A total of around 8,000 cases was reported in Guayaquil for this period. The characteristics noted included (1) a cyclic recrudescence of the infection; that is, years of severe epidemics, followed by years of lesser epidemics; (2) a progressive decrease in the number of cases in each 5 year period (1908-1912, 42 per cent; 1913-1917, 35 per cent; 1918-1922, 12 per cent; 1923-1927, 8 per cent; 1928 to 1930, when the disease was eradicated, 3 per cent); and (3) a decrease in the virulence of the germ or an increase in the resistance or partial immunity of rodents, as shown by a greater number of murine cases of plague without visible (latent or bacteriologic) lesions, but which could be identified by inoculation into guinea pigs.

In 1935, Guayaquil was reinfected from the *hinterland*, and the new epi-

demic lasted until April, 1939. From Guayaquil the disease spread by river or maritime traffic to other Provinces of the Coast, and by land to the Sierra or Inter-Andean region.

Of the coastal Provinces, Guayas had 7,863 cases with 3,113 deaths in Guayaquil, and 321 C and 141 D cases in the other 20 infected towns; El Oro Province reported 45 C and 21 D cases in 5 localities between 1909 and 1940; the Province of Los Rios, 50 C and 19 D cases in 3 localities, 1909-1936; and Manabi, 397 C and 109 D cases in 14 localities from 1913 to 1937. It is probable that there were some 8,800 cases, 3,500 deaths in the whole group of Ecuadorian coastal Provinces from 1908 to 1939.

Official reporting was more deficient in the Inter-Andean Provinces, but the accepted figure is a total of some 2,250 cases and 1,000 deaths. The official number of known cases was 1,215, with 585 deaths, in 131 hamlets and cities of Chimborazo Province; 171 C and 66 D cases for Tungurahua; and 68 C and 33 D cases for two towns in the Province of León.

In the Southern Zone, the infection which began about 1918 persists to the present day. There were 45 known C and 31 D cases for the Province of Cañar, and 1,404 C and 811 D cases for that of Loja (1925-1940).

INTER-ANDEAN PLAGUE

Plague spread from Guayaquil to the Andean Sierra by the Guayaquil-to-

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

Quito Railroad, which rises from sea level to 11,890 feet (3,609 meters, Urbina Station), to descend at its terminal (Quito) to 9,350 feet (2,778 meters). The total distance involved is about 288 miles (452 km.) and Huigra, the first mountain station, at an altitude of 3,900 feet (1,245 meters), is only about 110 miles (116 km.) from Guayaquil.

In its first period, beginning about 1909, plague invaded the railway stations through the transportation of rats and *X. cheopis* infected in Guayaquil. There were 915 C and 450 D cases in a dozen places on the railroad, the most serious epidemics being those in Alausi, 1916, 167 C and 106 D cases; Ambato, 1916, 42 C and 18 D cases, 1926, 101 C and 36 D cases; Sibambe, 1936, 96 C and 75 D cases; and Guaytacama, 1927, 53 C and 25 D cases. During this first period the epidemiology conformed to the rat-flea, rat-man type of contagion, with the exception of a notable incidence of pneumonic plague.

During the second period plague spread from the railway communities to the rural areas, and after a short time of dependence on railway plague, the rural infection became independent, with its own local epidemiological characteristics.

In general, rural Andean plague manifests itself as an apparently discrete enzoötic, this aspect being principally because of the low density of the rural population. It tends generally to have a seasonal distribution (during winter) although less so than along the coastal zone.

In the Andean zone the only province capable of maintaining plague infection is that of Chimborazo, and in that province, only the river basins. This may be because of a temperature and humidity favorable to flea activity, at least during the winter season.

These valleys are essentially agricultural, devoted to the growth of

grains, fruit, potatoes, and other products of the temperate zone. The inhabitants, mostly Indians, live in either isolated huts, or grouped in small hamlets, devoid of all comforts and hygiene. Among the factors influencing the occurrence of plague, may be mentioned those of agricultural-economic origin, such as type of farming (grain), dwelling construction (stone, clay, straw); those of climatic and topographical origin (rain in relation to agriculture, average humidity and temperature, altitude, etc.); those depending on social habits (promiscuity, dwelling, wakes, lack of change of clothing, drunkenness, etc.); and those of biologic origin (rats, fleas, guinea pigs, etc.).

BIOLOGICAL FACTORS

Rodents—Various authors have accepted the statement that in general domestic rats are scarce in the Sierra, where they were introduced by the Guayaquil-Quito Railroad since 1908. This statement has not been confirmed, but instead domestic species, especially *R. rattus* and *R. alexandrinus*, have been found to be universally distributed. In towns on the railway line a high percentage of *R. norvegicus* is not uncommon (Latacunga 60 per cent; Ambato 10 per cent; Huigra 5 per cent; Quito 50 per cent). In the Loja area rats are fundamentally field-dwelling, and are not common in the cities. The percentage which rats form of the total of rats and mice (*M. musculus*) varies in different localities. In the province of Chimborazo in general this percentage is 50; and for certain cities: Latacunga, 93 per cent; Ambato, 88 per cent; Riobamba, 32 per cent; Cañar, 80 per cent; and Loja, 7 per cent.

While local authors accept the fact that plague is related to rats in Guayaquil and in the railway stations on the road to Quito, they do not agree that

this mechanism is the most usual in the rural Andean zone.

Among the wild rodents which must be mentioned as of possible importance in plague are *Phyllotis fruticulus*, *Oryctolagus* sp and, especially, *Cavia aperea*, the last of which is found principally in a domesticated state in close contact with the Indian population, which uses it as the principal source of meat.

Other animals—In Loja is found the weasel and in the inter-Andean region, the *zorra o raposa* (*Didelphis paraquayensis andina*), the susceptibility of which to experimental plague has been verified by the author. The *chucuri*, long-tailed *mustela*, or bridled *mustela* (*Mustela frenata aureoventris*) is important as a natural enemy of rats and because of the possibility that *X. cheopis* might accidentally be found on it. Squirrels of the Loja zone do not appear to play a part in plague.

Fleas—The following fleas have been found by previous authors on rodents, guinea pigs, and man: *X. cheopis*; *P. irritans*; *C. londinensis*; *Ct. canis*; *Ct. felis*; *Echidnophaga galinacea*; *Hectopsylla suarezi*; *Leptopsylla musculi*; *Rhopalopsyllus cavicola* and *Tunga penetrans*.

In addition, the author has found on rats of the Loja zone, *Craneopsylla wolffhuegeli* and two species as yet unclassified; on rabbits, *Cediopsylla inequalis*; and on *Didelphis* and *mustelae*, various species at present undergoing classification.

Flea indexes—In Guayaquil *X. cheopis* is practically the only murine flea. In 1926 the *cheopis* index was 3.36 (Suarez). In 1941 it fluctuated below 1.

In the Sierra in 1926 the average *cheopis* index on *R. norvegicus* was 0.94 and on *R. rattus* and *R. alexandrinus* 1.27 (Suarez). In 1929–1930 the *cheopis* indexes were: Ambato 3.69; Alausi 0.87; Latacunga 0.96; Quito

0.3; and 0.0 in Guamote, Riobamba and Guaytacama. In 1942 *cheopis* fleas were found in Huigra, Yalancay, Gausuntos, Ceceles and Riobamba; this flea had not previously been reported in the last named city.

Lice and acari—The following have been found on rats: *P. spinulosum*, *L. echidninus* and *L. bacoti*; and on guinea pigs *Gyropus* sp.

DYNAMICS OF PLAGUE

We have seen that plague in Guayaquil and the railroad communities of the Andean region depended on plague-infected rats and fleas. Local authors maintain the thesis that in the rural Andean region plague does not involve the intervention of rats and rat fleas, but rather that of guinea pigs, which they consider reservoirs of the infection. Since *R. cavicola* of the guinea pig has not been recognized as a vector of plague from the guinea pig to man, and since as it has been stated, plague in guinea pig always precedes human cases, it has been supposed, without direct evidence, that the plague vector from the guinea pig to man is *P. irritans*. This, furthermore, could maintain man-to-man infection, favored by the custom of holding wakes and of distributing the clothing of the plague dead among the relatives.

A detailed study undertaken in 1940 and 1941, with regard to human fleas and fleas of domesticated guinea pigs, revealed that in 1940, of 6,143 fleas collected from humans, beds, clothing, etc., only 122 (1.67 per cent) were not *P. irritans*; 103 of these were *R. cavicola*, which came from only 2 of 54 localities studied. In 1941, of 7,225 fleas of similar origin, only 130 (1.6 per cent) were not *P. irritans*, 102 of these being *R. cavicola*.

In 76 localities in 1940, 10,116 fleas were caught on guinea pigs, including 8,309 *R. cavicola*; 718 *P. irritans*; 68 *C. londinensis*, and 991 unclassified. In

27 localities only *R. cavicola* were found.

In 1941, in 43 localities, 5,696 fleas from guinea pigs were classified. *P. irritans* were scarcely 0.53 per cent of the total (in place of 7 per cent in 1940), and in 37 localities the guinea pigs did not have any *P. irritans*. Since the study was made in the second half of 1940 and the first half of 1941, the difference might be explained by seasonal conditions and "hibernation" of *P. irritans* in guinea pigs.

From the previous data it may be gathered that *P. irritans* does not satisfactorily explain the distribution of Andean plague. Nor is it possible to attribute to it a very important epidemiological rôle when it is considered that the human flea lacks significance in plague in other countries and its capacity as a vector is, experimentally considered, limited. The author cannot accept the local theories crediting importance to this and other fleas habitually found on rats and guinea pigs. He feels that the Andean zone should be divided in two sectors with regard to the vector: first, that including up to 8,900 to 9,900 feet (2,700 to 3,000 meters) altitude, with a humidity and temperature adequate, at least seasonally, to the breeding of *X. cheopis*; and second, cold regions located above 8,800 feet, and in general all areas of an altitude above 9,900 feet in which *X. cheopis* can neither live nor breed in case they should reach them accidentally.

In the localities of the first Andean sector, plague epidemiology shows the classic form observed in rural areas; that is, epizootic transmission from rat to rat by *X. cheopis* and human "accidents" more or less epidemic in character, involving the intervention of the same flea.

In the more elevated regions, where *X. cheopis* is absent, *C. londinensis* may play an important rôle, in view of its

biologic characteristics and its preference for rat nests. In considering the lesser capacity of this flea to become infectious and to transmit plague, as contrasted with *X. cheopis*, it should be explained that plague in the high altitudes of the Andes rarely reaches man, having a sporadic character with the occurrence of a few, strictly familial, cases.

In view of the common observation of the participation of the guinea pig in plague, one might well attribute a preponderant rôle to this animal as a reservoir of the infection. However, the author does not accept anything but an accidental participation of guinea pigs in plague.

The guinea pig does not explain the origin of Andean plague, since its capacity as a reservoir is doubtful in view of its enormous susceptibility. Its correlation with plague is not perfect, and it appears rather to act as a reinforcing factor in the infection, serving as an intermediary of plague between rats and man by the liberation, at its death, of the infected fleas which it has previously caught at soil level.

Since the guinea pig is a co-dweller in the human habitation of the Sierra, it is easy to suppose that, acting as a "flea-trap," it continually collects free fleas found on the ground level. In the climatic conditions of the Sierra, the majority of contacts between rats and fleas take place in the burrows, since the range of the exterior meteorologic conditions is unfavorable to the flea and impedes the free circulation of this insect in the out-of-doors.

Most of the plague phenomena occur, therefore, in the interior of the caves, and the plague infected fleas only abandon these burrows when the external atmospheric conditions become more favorable and when the subterranean epizootic has done away with the rat population in the nests. It is logical that under these circumstances,

the first recipient of the plague infection carried by such fleas, should be the guinea pigs which run freely above ground, and that these infected fleas should only reach man after having caused an epizootic in, and death of the guinea pigs.

A series of factors, principally climatic and agricultural in origin, govern this epidemiology by favoring murine migrations from house to field and vice versa. On the other hand, the number of immune rats remaining after an epizootic episode, and the number of susceptible animals added to the rat population through migration or natural increase, are important factors in the epidemiology of murine plague. It is possible that the most important reservoir of plague in the Ecuadorian Sierra may be the fleas themselves, which remain infected from one plague season to another, and through which the infection is revived when, after the harvest, a new population of susceptible rats returns to the dwellings, which happens just at the season of the year climatically most favorable to the transmission of plague from fleas to rats.

The study on which these observations are founded, included numerous other epidemiologic details which permit an explanation of the mechanism of plague in the inter-Andean zone on a

basis which agrees better with the facts than theories previously advanced.

SUMMARY

Rural plague of the inter-Andean region conforms to the classic rat-flea mechanism, with changes imposed by the climatic characteristics under which the biologic activities of the rats and fleas are conducted. All the other phenomena foreign to this rat-flea mechanism should be considered simply accidental manifestations without any fundamental influence on it. However, such phenomena may on occasions appear to be predominant because they are the features most easily detected in the usual epidemiologic survey.

Endemic Typhus Fever in Jamaica, B. W. I.

COLONEL HARRY PLOTZ, M.C., A.U.S., CAPTAIN THEODORE E. WOODWARD, M.C., A.U.S., MAJOR CORNELIUS B. PHILIP, SN.C., A.U.S., CAPTAIN BYRON L. BENNETT, SN.C., A.U.S.

Army Medical School, Army Medical Center, Washington, D. C.;

AND

DR. K. LEIGH EVANS

Government Bacteriologist, Jamaica, B. W. I.

IN spite of the fact that it is generally believed that endemic typhus fever is a common disease in the West Indies, there are few reports to substantiate this view. In fact, Zinsser¹ in a comprehensive survey of typhus fever does not indicate its presence in the Caribbean area up to 1937. The *Epidemiological Report of the League of Nations*, 1936² does not record the presence of typhus fever in Jamaica, nor do the careful records of the hospitals of the United Fruit Co. indicate its presence. Typhus fever was not noted in the records of the United Fruit Co. for two successive years in Costa Rica, Cuba, and Jamaica, although the records covered the case histories of 47,000 in-patients and a half million out-patients. The health authorities in Jamaica state that typhus had not been recorded in Jamaica prior to 1941, when the cases comprising this report were noted.

The occurrence of typhus in Puerto Rico has been reported by Pons³ who records 8 cases presenting typical clinical symptoms of endemic typhus with a positive Weil-Felix agglutination (OX₁₉). In a later paper⁴ this author

substantiated his previous findings by reporting a rise in agglutination titer (OX₁₉) in 20 additional cases. The author's conclusion that typhus fever was present is justified even though the agent was not isolated. These and some additional Puerto Rico cases since have been tabulated in the *Public Health Reports*, and 2 cases have been diagnosed as endemic typhus in our laboratory by the complement-fixation test.

In 1937, the first case of endemic typhus was reported from Martinique.⁵ The illness was characterized by an acute onset with headache, continued fever, and a rash. The Weil-Felix agglutination (OX₁₉) titer rose from 1:300 to 1:1,000. No agent was isolated.

The present report deals with the occurrence of endemic typhus in Jamaica in 1941 and 1942. In a period of 5 months, 68 probable cases were diagnosed in natives.

The first case of typhus occurred in a native Jamaican laborer in December, 1941, the diagnosis being made by Captain T. E. Woodward. This man

complained of fever, headache, and generalized pains, and was admitted to the Army Hospital. The patient appeared moderately toxic and, outside of conjunctival injection and a few rales at the bases of the lungs, nothing abnormal was found. The temperature ranged from 100 to 105° for 14 days and fell by lysis. In spite of careful search, no rash was observed. This native had a cafe-au-lait colored skin, and a slight rash may have been missed. The Weil-Felix agglutination (OX₁₉) was 1:500 on the 8th day of illness, 1:1,000 on the 9th day, and 1:2,500 on the 12th day. Complement-fixation tests performed on specimens of serum withdrawn on the 8th and 12th day indicated that the patient's infection was of the endemic type of typhus.⁷

This case directed attention to the likely presence of murine typhus on the Island which in due time was confirmed.

In all, 68 cases were found in whom a diagnosis of endemic typhus was made, chiefly in native residents of Kingston. Most of the cases came from the thickly populated, poorer sections of the city where rats are common. Thirty-three of these cases were seen in the hospitals in Kingston. The prevailing symptoms are indicated in Table 1. The onset is usually sudden with severe headache, generalized pains, and temperature which is maintained for about 14 days when it falls by rapid lysis. Rash was only seen in 7 cases. In these cases the rash was maculopapular in character appearing on the body, arms, and legs, and was typical in character. No rash was observed in 26 cases but may have been masked in some instances by the dark skin of the natives. However, some cases, which were carefully observed, showed no rash, and hence the possibility of typhus occurring without an eruption must be considered.

All of the cases had a Weil-Felix

TABLE 1

Summary of Symptoms of 33 Cases

Symptoms	Number	Per cent
Positive Weil-Felix	33	100
Positive Comp. Fix. Typhus	33	100
Headache	25	76
Backache	16	48
Arthralgia	16	48
Diarrhea	9	27
Chills	8	24
Nausea Abd. pain	8	24
Rash	7	21

(OX₁₉) agglutination, ranging from 1:500 to 1:5,000, in most of whom a rising agglutination titer was observed. Specimens of serum examined for complement fixing antibodies were positive at least late in all cases. In some instances a negative fixation was obtained early in the disease which became positive subsequently. In the sera of most patients, complement fixing antibodies were present which reacted with an endemic rickettsial antigen but not with an epidemic rickettsial antigen. In a few cases, convalescent sera had relatively large amounts of complement fixing antibody against an endemic antigen and small amounts against an epidemic antigen.⁷

The 35 remaining cases were seen by local physicians. The diagnoses in these cases were made by the history of the case, a positive Wei-Felix agglutination, and in all instances a positive complement-fixation reaction for endemic typhus.

Attempt was made to isolate virus from a few cases but these were unsuccessful. In addition, ectoparasites of rats trapped in homes in which certain of these cases occurred, were injected into guinea pigs, but no agent was isolated. Two of these guinea pigs, receiving respectively, 13 fleas (*Xenopsylla cheopis*), and a pool of 7 fleas, 2 sucking lice (*Polyplax spinulosus*) and 5 tropical rat mites (*Lyponysus bacoti*), showed sporadic, low fevers, and later resisted controlled challenge doses of endemic typhus

virus (Wilmington strain). This suggests that the ectoparasites in these tests probably carried the agent.

The evidence presented here indicates that endemic typhus fever exists in Kingston, Jamaica. The fact that 68 probable cases were found in a period of 5 months suggests that the disease is more common in Jamaica than was formerly believed. The clinical and serological evidence indicates that the outbreak was endemic typhus even though the etiological agent was not isolated.

NOTE: The authors wish to thank Major Hallinan, Chief Medical Officer, Jamaica, and his staff for their coöperation, as well as Lt.

K. Wertman for his assistance in performing the complement-fixation tests.

Rapid Detection of the Production of Acetyl-Methyl-Carbinol*

LT. L. M. COBLENTZ, SN.C.

85th General Hospital, Nichols General Hospital, Louisville, Ky.

THE Voges-Proskauer test is one of the most important means of differentiating between strains of the genera *Escherichia* and *Aerobacter*. Various workers have recommended incubation periods of anywhere from 5 days down to 6 hours at 30° C. or 37° C. It is not within the scope of this brief paper to go into a detailed discussion of the V.-P. test. If demonstration of the production or non-production of acetoin could be encompassed within an ordinary laboratory working day (8 hours) such a procedure would be advantageous to laboratory workers.

There are several recent modifications of the V.-P. test. Werkman (1930)⁴ suggested 4 days' incubation at 30° C. and the use of FeCl₃ as a catalyst. To 5 ml. of culture he added 2 drops of 2 per cent solution of ferric chloride then 5 ml. of a 10 per cent NaOH solution. (The ferric chloride should be added before the alkali to prevent marked flocculation.) A positive test is indicated by a deep copper coloration beginning at the surface and after a few minutes extending throughout the medium.

O'Meara (1931) suggested the following medium to be used for the Voges-Proskauer test:

Sodium chloride	5.0 gm.
Magnesium sulphate	0.2 gm.
(NH ₄) H ₂ PO ₄	1.0 gm.

* The work herein described was made possible through funds of the Engineering Experiment Station, Iowa State College, Ames, Iowa.

K ₂ HPO ₄	1.0 gm.
Sodium citrate	2.77 gm.
Glucose	5.0 gm.
Sodium fumarate	10.0 gm.
Distilled water to.....	1,000.0 ml.

He suggested the addition of about 0.25 gm. of creatine to 5 ml. of culture (grown at 37° C. for 24 hours) followed by 5 ml. of 40 per cent KOH. With O'Meara's technic³ the red coloration of a positive V.-P. test appears in several minutes and increases with agitation of the tube contents.

Levine, Epstein, and Vaughn (1934)² combined the reagents (40 per cent KOH and creatine) suggested by O'Meara into a single solution consisting of 40 per cent KOH plus 0.3 per cent creatine. Their technic was as follows:

A small loopful (1½ mm. diameter) of a young agar slant culture was introduced into about 3 ml. of Difco M.R.- V.-P. medium, the mixture incubated at 30° C. for 6 to 7 hours, after which the creatine-alkali test reagent was added.

Readings were taken after 1, 2, and 4 hours. The authors tabulated their results as follows:

TABLE IV *
Voges-Proskauer Reaction on 202 *Aerobacter*
Strains Employing 6 and 7 Hour
Cultures at 30° C.

Time Elapsed After		Positive Reaction	
Addition of Test Reagent	Inoculation	Number	Per cent
1 Hour	7-8 Hours	157	77.8
2 Hours	8-9 Hours	195	96.5
4 Hours	10-11 Hours	202	100.0

* From Levine, et al. (1934)

It is evident from the table presented that with the technic of Levine, Epstein, and Vaughn, the time required for the completion of the V.-P. test may be reduced to a maximum of 11 hours.

Barritt (1936)¹ made no attempt to reduce the time required for the V.-P. test but tried by the use of alpha naphthol to make the test more sensitive. Barritt's technic is stated by himself as follows. "I have therefore employed cultures in 6 x 5/8 in. tubes of glucose phosphate broth (Ministry of Health, 1934) made with Difco bacto-peptone, which appears to be suitable for this test. After 3 days' incubation at 37° C. 1 cc. of culture was placed in a 6 x 3/4 in. test tube, to which were added 0.6 cc. of a-naphthol (5 per cent alcoholic solution), and 0.2 cc. of KOH (40 per cent solution). Equally good results were obtainable with 0.5 cc. of a 6 per cent solution of a-naphthol and 0.5 cc. of a 16 per cent solution of KOH." Using the foregoing technic Barritt obtained positive reactions in 2-5 minutes after the addition of the reagent.

The study herein presented was undertaken with two objectives in mind, namely: (1) to ascertain if production of acetoin (V.-P. test) could be detected within 8 hours, (2) the effect of temperature (30° C. and 37° C.) of incubation on the proportion of positive V.-P. tests.

In the experiments to be described, 216 known strains of V.-P. positive organisms were used. The following technic was employed.

A massive inoculum consisting of a loopful (2-3 mm.) of a 12 hour nutrient agar slant culture was introduced into 2 ml. of Difco M. R.-V.-P. medium (contained in 18 mm. tubes). The tubes were incubated at 30° C. for 6 hours and then 0.6 ml. of a-naphthol (5 gm. of a-naphthol in 100 ml. of 95 per cent ethyl alcohol) added, followed by 0.2 ml. of 40 per cent KOH to which had been added 0.3 per cent

creatine. The tubes were then shaken vigorously for 30 seconds to 1 minute.

The foregoing experiment was repeated using 37° C. as the incubation temperature.

The results of both of the above experiments are presented in Table 1. A positive reaction was characterized by an intense pink to rose coloration developing in a few seconds to 5 to 10 minutes after the reagents were added. In both experiments 10 strains of *Escherichia coli* were used and were found to be negative.

TABLE 1
Voges-Proskauer Reaction of 216 Strains of the Genus Aerobacter Employing 6 Hour Cultures at 30° C. and 37° C.

Minutes After Addition of Reagent	Incubation Temperature			
	30° C.		37° C.	
	No. Pos.	% Pos.	No. Pos.	% Pos.
10	215	99.5		
30	215	99.5	190	87.7
60	215	99.5	198	91.7
120	215	99.5	200	92.6
400	215	99.5	200	92.6

From Table 1 it will be noted that at 30° C. 215 of the 216 *Aerobacter* strains gave a positive reaction within 10 minutes after the addition of the reagents. Thus, at 30° C., the total time consumed in the test, from the time of inoculation to the appearance of a positive test, was less than 6 hours and 15 minutes. In marked contrast, it is noted that at 37° C., 30 minutes after the addition of reagents, only 190 (87.7 per cent) of the cultures were positive and, even after 400 minutes, only 200 (92.6 per cent) positive reactions were obtained.

From the data herein presented, it may be concluded:

1. With the technic herein described, detection of a positive V.-P. test may be consummated in less than 7 hours.

2. An incubation temperature of 30° C. is preferable to 37° C. for the detection of the

maximum number of positive Voges-Proskauer tests.

The Danger of Botulism

IVAN C. HALL, PH.D., F.A.P.H.A.

Columbia-Presbyterian Medical Center, New York, N. Y.

ALTHOUGH the high fatality rate of botulism makes it a spectacular disease, botulism has never been regarded as a major health problem. A recent tabulation¹ shows, however, that during the period 1899 to 1941, as many as 359 outbreaks with 1,024 cases and 669 deaths were recorded in the United States and Canada. Many of these outbreaks occurred in the western states, particularly in the Rocky Mountain Region where the present writer and his associates reviewed and reported as many as 32 human outbreaks with 107 cases and 83 deaths, as well as several outbreaks involving burros, poultry, and mink.²⁻⁵

Most of these outbreaks were caused by eating improperly home-canned vegetables, and in view of the current shortage of food in this country and the consequent plans of many housewives to can as much food as possible this year, a timely warning may help to prevent a recurrence of the catastrophic outbreaks of botulism which followed the widespread use of the "cold-pack" method of home-canning during the first World War.^{6, 7}

The first principle in the control of botulism is governmental regulation and inspection of commercial processing of all preserved food.⁸ As a result of several devastating outbreaks of botulism caused by eating commercially canned ripe olives, this principle reached its highest development in California⁹ but has been so widely adopted that very few outbreaks of botulism have been ascribed to commercially canned foods in recent years. We are therefore

mainly concerned with the problem of home-canning.

This is primarily a problem in public education of housewives and others engaged in canning and serving foods. To undertake such education is a worthwhile effort in every community; it should be done under the auspices of every health department as a means of conserving food which would otherwise be wasted, at the same time avoiding the danger of food poisoning.

There are many women in this country who are well grounded in the fundamental principles of bacteriology as applied to home-canning, who intelligently and successfully, year after year, use controlled steam-pressure or intermittent methods of sterilization in canning, who are ever conscious of the danger of botulism in spoiled canned foods, who never taste or serve spoiled food, and who always re-cook canned foods before serving them. Deaths from botulism seldom occur among these housewives and their families. Such women in every community would make excellent instructors for groups interested in the art of home-canning.

There is also, unfortunately, a very large group of women who have little or no knowledge of bacteriology, who use antiquated "cold-pack" or other inadequate rule-of-thumb methods of canning, and who, having much spoilage, are vaguely conscious of an ill-defined element of danger which they attempt to avoid by tasting each jar of food before serving it. No doubt thousands of jars of harmlessly spoiled home-canned foods are discarded as a

result of this common practice, but, from time to time, a jar is encountered which contains botulinus toxin, resulting in the death of the "human guinea-pig" and often domestic fowls and other animals as well, though in these instances the other members of the family may not suffer. This is an important and relatively easy group to reach.

Finally, there is a group of people who are at the bottom of the ladder, educationally, socially, and economically, who use the crudest methods of home-canning, who are apparently oblivious to the danger of eating spoiled food and will eat anything out of a jar or can that looks like food and doesn't taste too bad. In some instances canned foods fermented by *Bacillus botulinus* have been especially relished for their exotic flavor or they may have been highly seasoned to mask spoilage. When botulism occurs under these conditions it usually takes a dramatic toll. This group is naturally the hardest to reach because aggressive personal instruction is required, but the effort is likely to pay good dividends.

It is not the purpose of this article to go into detail on the subject matter of such instruction, or to discuss the relative merits of the various methods now being advocated in farmer's bulletins.¹⁰

It is recognized that while the pressure-cooker, properly operated, provides the easiest and best method of home-canning there is likely to be a shortage of such cookers. Correct operation should be emphasized; we have recorded three outbreaks of botulism caused by foods supposed to have been sterilized in pressure-cookers.

Emphasis should undoubtedly be placed upon the following items:

1. Processes:

- a. Careful selection of sound produce.
- b. Careful cleansing, and when indicated, blanching, of produce, as well as general

cleanliness to minimize the bacterial load to be sterilized.

- c. Principles and correct application of intermittent sterilization, as a valuable and available substitute for cooking under steam-pressure.
- d. Use of other methods of preserving food, notably drying, salting, and pickling in which there is little or no danger from botulism.

2. Consumption of home-canned foods:

- a. Significance of turbidity, gas-production, softening and odor as criteria of spoilage.
- b. Danger of eating or even tasting freshly opened home-canned foods, especially if signs of spoilage are present.
- c. Fact that certain foods, notably beets, chili, sometimes beans, and possibly other foods, may show no easily recognizable signs of spoilage even though botulinus toxin is present.
- d. Destruction of botulinus toxin by always boiling home-canned foods for at least 5 minutes before serving.
- e. Harmlessness of the spores of *Bacillus botulinus*.

3. Safe methods of disposal of contaminated foods by boiling in strong lye-water to avoid:

- a. Killing poultry and other domestic animals.
- b. Excessive pollution of the soil with the spores of *Bacillus botulinus*.
- c. Loss of usable containers.

4. In case an outbreak occurs:

- a. Character of symptoms of botulism and other forms of food poisoning.
- b. Prompt reporting of suspicious symptoms to physicians.
- c. Diagnostic value of symptoms in fowls and other domestic animals in case humans have tasted same food.
- d. Inadequacy of botulinus antitoxin for treatment of advanced botulism.
- e. Saving of remnants of food for epidemiological and laboratory studies of food-poisoning.

California Adopts Revised Regulations Regarding Infant Diarrhea

Wilton L. Halverson, M.D., Dr.P.H., California Director of Public Health, has announced that the California State Board of Health has recently revised its definitions as to what constitutes a reportable case of diarrhea of the newborn, defining the disease as diarrhea in infants up to 3 weeks of age occurring in a hospital giving maternity service. Diarrhea shall be considered to exist when an infant has four or more loose stools in 24 hours, except in the case of entirely breast fed infants who show no other signs of illness and who are

gaining weight. Strict regulations are prescribed for the isolation of infected infants and their contacts.

J. C. Geiger, M.D., Director of the Department of Public Health, City and County of San Francisco, reports an elevated rate of infant mortality for the first 4 months of 1943 and directs attention to the new requirements relating to deaths from diarrhea in infants. The infant mortality rate for this period in 1943 is 45.8, whereas for the corresponding period in 1942 it was 38.0.

Gearing Dental Public Health to Meet Wartime Conditions

WALTER J. PELTON, D.D.S., M.S.P.H.

*Dental Surgeon, State Relations Division, U. S. Public Health Service,
Washington, D. C.*

THE new socio-economic conditions created by the war have changed the dental public health picture to such an extent that traditional approaches to the problem are no longer satisfactory. A rapid summary of the situation shows:

There is a job for everyone who will work. Relief rolls are reduced to only those who are unemployable.

So-called medical indigents are fewer than ever before.

Retired individuals, and women who formerly did not seek or need employment, are now working in offices, factories, and hospitals as a patriotic duty and not particularly for personal gain.

Workers in factories which have no dental provision in their respective industrial hygiene programs frequently find that appointments with the family dentist, if they can get to him, are very hard to obtain, if at all.

Reports from several factories have indicated that more time is lost on account of the lack of dental care than for any other reason. In certain areas workers sit in dental offices hoping that some person having an appointment will not keep it.

The armed forces, when commissioning dentists in the Reserve Corps during peacetime, were not concerned with the location of the men who were placed on their rolls. This is as it should be. Subsequent to the declaration of war, demands for dentists caused men to volunteer, and leave vital and poorly supplied areas. The draft and the activities of recruiting boards took others. While these events served

military purposes, the distribution of dentists remaining in the population was not taken into account. Naturally there has been a decrease in dental services in many communities and a depletion in others.

The need of the armed forces for professional personnel has also created another unique situation. People and communities having financial resources have been reduced to the status of medical and dental indigents because they are unable to obtain services. In addition, new industrial areas have created community and health needs in places where no facilities previously existed.

We are told that very soon more than 50 per cent of production will be for war purposes. Increased production has increased the purchasing power of many people. Even though taxation will reduce the cash incomes to some extent, it is expected that a restriction of purchasable commodities will leave a large proportion of the incomes to be spent for personal services. This fact, coupled with the increase in employment, is creating a demand for long neglected dental services. This means that the established practitioners have less rather than more time to devote to problems arising on account of the shortage of dentists.

A lowered standard of nutrition is a future possibility. The rationing of

sugar is looked upon by most of the dental profession as highly desirable, since the relationship of carbohydrate consumption to dental caries has been shown to exist. On the other hand, the absence of certain food constituents may cause a higher incidence of some diseases. Reports from England already indicate that there is a rise in the incidence of Vincent's infection. The newer forms of treatment used in Britain to control Vincent's infection include the use of certain food constituents.

Conventional dental practice has been established on the basis that if a given community could support a dentist, one would move into the area. It then followed that the needs of all the people within twenty or thirty miles would thus be met. Gasoline and tire rationing, coupled with higher incomes, now creates a problem never before visualized. Restricted civilian travel indicates that serious problems of distribution of services are ahead, not only in the newly constructed housing developments surrounding more populated areas, but in more rural areas as well. Programs utilizing centralized dental clinics are finding that the once helpful lay organizations no longer have the gasoline or tires to expend in transporting school children to the clinics.

Due to the lack of equipment and dental supplies, it is becoming increasingly difficult to purchase the necessary equipment for new offices or clinics. Existing clinics must, therefore, be operated more efficiently than ever, and the equipment of dentists who have gone into the armed services must be redistributed.

It must be admitted that even in peacetime the public as a whole has not received adequate dental care; in fact, only a small proportion has been economically able to obtain even the approach to ideal services. In wartime the construction of highly refined and

time consuming precision appliances in dentistry should give way to basic routine treatment which will render the maximum amount of health services to the largest number of people. One may assume that much could be accomplished in this direction through voluntary effort.

The dental caries problem is different from other health problems. Nearly the whole population suffers from this disease. Dental studies show that after 6 years of age permanent teeth are attacked at the rate of $\frac{3}{4}$ of a tooth per child per year. The annual incidence of new defects, added to those already accumulated, presents a health problem of the first magnitude. At the moment there are no proven measures to prevent the inception of dental caries. The only effective method we have of preventing the sequelae of dental caries (infections and loss of teeth) is by utilizing remedial measures. In other words, without considering other oral diseases, to control dental caries dental service is continuously needed by practically everyone.

The problem resolves itself then, to the basic question—How can civilian dental needs (general health conservation and care of specific dental diseases) be met under the conditions created by the war?

To deal effectively with the points raised, it is necessary that:

1. Dentists remaining in civil life be distributed in the population according to the most favorable ratio permissible.

2. Industrial and vital war areas be supplied with dental facilities in order that no person shall be absent from his job because of the lack of basic dental services. This applies to both the factories and the nearby housing developments.

3. The usual school dental service programs be extended to include services to high school pupils. The gap in services between elementary school children and those in high school should be closed as rapidly as possible. The man power to supply dental service to these categories may have to be assigned by

procurement agencies, if objectives cannot be attained by voluntary efforts.

4. Sub-professional personnel be utilized to the fullest possible extent.

5. In critical areas it may be wise to request that highly refined mechanical dental appliances and replacements be not constructed until some more opportune time, and thus permit a health service type of dentistry to be rendered to a large number of patients.

6. In extreme circumstances, a system of priority of patients, which will give first con-

sideration to the most productive members of the community, may be advisable.

State and local dental committees studying the problems of adequate dental care, in an attempt to foster the war effort by maintaining civilian health, would be extremely wise if they included on their committees representative individuals to act for the consumer groups—the general public.

Milk Laboratories in War Areas*

LUTHER A. BLACK, PH.D.

*Sanitation Section, States Relations Division, U. S. Public Health Service,
Washington, D. C.*

LABORATORY methods for controlling the sanitary quality of market milk have been used in this country for about fifty years. Nearly forty years ago the first committee was appointed by the American Public Health Association to standardize such methods. Since then eight editions of *Standard Methods of Milk Analysis* have been published, and supposedly everyone in this country engaged in official analysis follows Standard Methods.

For years we have known that different laboratories fail to obtain the same result upon bacteriological analysis of the same milk supply, and much has been published on the inherent errors and inaccuracies of the methods. These differences assumed greater importance when recognition of the value of milk in nutrition resulted in its greater use by our increasing armed forces as well as by civilians, with consequent analysis of fluid milk by various official agencies.

In the interest of increasing the accuracy and dependability of bacteriological milk analysis, survey forms were prepared based upon Standard Methods (7th edition). These forms included one for the agar plate method, and one for the direct microscopic and methylene blue reduction methods.

Using these forms, surveys were made in defense areas, commencing in September, 1941. Laboratories doing

official analyses were visited and observations made of equipment, general preparation and sterilization of material, and the actual technic of making the analyses, reading the results and recording or reporting these. With the view of securing closer compliance with Standard Methods, correct procedures were demonstrated and suggested and a blank copy of the survey form was left as a guide. A checked copy of the form with written recommendations regarding the deviations in equipment and technic was submitted later to each laboratory concerned.

The survey forms were revised in January, 1942, based upon the experience with the first hundred laboratories surveyed in 20 states east of the Mississippi River. In order to avoid misunderstanding, a number of items were amplified, frequently after obtaining, directly from members of the Standard Methods Committee, an interpretation of exactly what was intended. A few inconsistencies and errors in Standard Methods were corrected, and a few items not specified in Standard Methods were included. The additional material not in Standard Methods, but found necessary by experience, was taken up previously with the referee of that section of Standard Methods and included other ways of obtaining the same result (such as maximum-minimum thermometer instead of thermometer in container of liquid) or actual listing of something assumed in Standard Methods (such as using a separate pipette

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

for each sample, and for each dilution).

An additional form was also prepared on which certain miscellaneous information not required by Standard Methods could be recorded, such as space and facilities of the laboratory. This form also listed the requirements of Standard Methods on Sampling, and certain requirements of health department practice pertaining to milk analysis where communities operated under the *Milk Ordinance and Code* recommended by the U. S. Public Health Service.

While earlier surveys had included only the larger defense areas, after war

was declared an attempt was made to include all laboratories in each state doing official analyses, inasmuch as most places large enough to maintain a laboratory either were or would be war areas.

Of 281 laboratories making official bacteriological milk analyses in the 40 states (including the District of Columbia) surveyed to date, 276 used the agar plate method. Of these, 27 also used the direct microscopic examination, and 28 used the methylene blue reduction method for samples of producers' milk. In addition to these 276 labora-

* DEV = Deviation; UND = Undetermined; NOT = Not Used

ories, 4 laboratories surveyed used the direct microscopic method and one additional laboratory used methylene blue reduction as the sole procedure in the control of retail pasteurized and raw milk. Since the agar plate method was so universally used, it was believed that a summary of the procedures used by those laboratories would be of most interest. Accordingly, compilations were made of the number of laboratories conforming to, and deviating from, each item of equipment, preparation, technic, and reporting required by Standard Methods.

In the interest of clarity, the figures presented in the following tables list only *deviations*, items *undetermined* because of local conditions at the time of the survey, or items *not used* in the particular laboratory. Thus, at a glance one may single out common deviations, and some of these will be discussed briefly. The entire survey form for the agar plate method has been divided into portions, and the material arranged so the results could be tabulated. The last 161 of the 276 laboratories reported upon were recorded on the revised forms and, in preparing the tables, the results of the first 115 laboratories recorded on the earlier form were also tabulated upon the present forms. This resulted in some instances in unduly large figures for items marked *undetermined*, where such an item was not included on the original forms. Likewise, the earlier surveys were based on the 7th edition of Standard Methods while the revised forms, based on the 8th edition, included four additional items. Consequently, these were marked "not used" when transferring the earlier surveys to the revised forms.

The requirements of Standard Methods pertaining to *apparatus*, are listed in Table 1.

As shown in *Item 4*, half of the laboratories were using, in whole or in part, pipettes that did not meet the speci-

cations required by Standard Methods. Their use naturally resulted in errors in measurement also, as will be seen later. Similarly, nearly half of the laboratories used dilution bottles without markings, consequently errors in volume (which were quite common, as will be seen later) would not be observed. It is interesting to note that nearly 20 per cent were not using solid stoppers or leak-proof closures, with consequent failure to agitate the dilutions as required by Standard Methods (also to be seen later).

Less than 20 per cent of the laboratories had checked the accuracy of the thermometers used in incubators, as shown in *Item 7*. Considering the incubators proper, 75 per cent had suitable incubators, although less than half had checked the temperature variations of the incubators in use. Approximately one-fourth of the incubators in use were smaller than the minimum required by Standard Methods. As far as could be ascertained, all incubators were kept in a room of suitable temperature, being one of the five items of the total 165 items of equipment and procedure recorded on this form for which deviations were not noted in any laboratory. The last requirement in item 8 appeared in the 8th edition only, accounting for the large numbers in the "not used" column.

As shown in *Item 9c*, the form included one item of equipment not now required by Standard Methods, namely a constant temperature water bath or incubator for holding melted agar. Since lack of this control was the most common reason for trouble with precipitates in using the standard milk agar, this item was included but marked (desirable).

It is important to note (*Item 9d*) that only half of these official laboratories had an approved colony counter. It may be said now that in spite of the usual deficiencies in other equipment

and common errors in technic, some of the greatest errors in results were due to failure of laboratories to observe the actual colonies present on their own plates, usually due to lack of, or an inadequate, counting device

The information on hot air ovens and steam pressure sterilizers is presented in *Item 10*. To many the least important requirement in Standard Methods is that concerning checking temperature variations within the hot air oven. Usually laboratories tend to use higher

temperatures or longer periods of sterilization than the minimum, or exceed in both respects. Occasionally, however, a laboratory will operate the oven at the minimum time and temperature listed in Standard Methods, without realizing there may be a number of degrees variation within the oven. A few laboratories were visited in which they had discovered this by sad experience. It is to be noted that over one-fifth of the laboratories felt able to operate their sterilizing ovens without

* DEV = Deviation; UND = Undetermined; NOT = Not Used

thermometers. Only half of the steam pressure sterilizers in use were equipped with thermometers.

The requirements of Standard Methods pertaining to the general *preparation* and sterilization of materials, media and dilutions, are presented in Table 2. The sterilization procedures are summarized in *Item 12*. In general these were satisfactory, although lack of control by thermometer is shown, particularly in the steam sterilization.

The cleansing of glassware, shown in *Item 13*, was, as would be expected,

apparently well done in almost every laboratory.

The standard tryptone glucose extract agar was in use by 80 per cent of the laboratories, over 90 per cent of which added skim milk, 85 per cent of the latter using this without trouble with precipitates (*Item 14*). However, only 20 per cent of the laboratories checked the final pH of the media, and only 5 per cent kept a record of this detail.

The deviations in dilutions are shown in *Item 15*. Only 10 per cent of the laboratories had ever tested the suita-

bility of the water used for dilution. Deviations in volume were quite common, less than 40 per cent being within the tolerance allowed. Variations of 10 ml. per 99 ml. blanks were not infrequent, and an extreme variation from approximately 60 ml. to 140 ml. was observed. Certain aspects of deviations were noted separately (segregated by parentheses in the tabular material) for the 135 laboratories deviating in one or more of those four requirements.

The requirements of Standard Methods pertaining to *technic* in making dilutions are summarized in Table 3.

The agitation of samples is summarized in *Item 17*. In general the retail samples were well mixed, and 80 per cent of the laboratories did this immediately before removal of the portion for analysis. Samples in smaller bottles

and vials, however, were not agitated, as prescribed, by a considerable portion of the laboratories. Similarly, a majority of the laboratories failed to agitate dilutions (*Item 18*) as vigorously as prescribed in Standard Methods. A number of laboratories did not use small sample bottles or vials, or used other methods with milk in such containers, accounting for the larger numbers in the "not used" column.

In *Item 19* it may be seen that inaccurate volumetric measurements were made in over half of the laboratories, partly as a result of not having standard pipettes, and partly due to improper manipulation.

Similarly, errors were made in measurement of the dilution itself, as may be seen in *Item 20*. *Item 21* shows that over one-third of the laboratories

* DEV = Deviation; UND = Undetermined; NOT = Not Used

surveyed did not make suitable dilutions to yield the required number of colonies per plate for proper accuracy.

The deviations in *plating* and *incubation* are shown in Table 4. Over one-third of the laboratories did not plate out controls regularly. The large number of laboratories having no constant temperature control over melted agar resulted in the large numbers in the "*undetermined*" column concerning the temperature of agar when poured. The actual technic of plating was fairly well done in general, as would be expected in laboratories accustomed to plating.

There was failure to control the temperature of incubation in accordance with Standard Methods, comparatively few laboratories doing this correctly, as shown in *Item 23*. Temperatures of 33°–42° C. were observed in incubators

supposedly operating at 37° C. Only five laboratories were noted in which the optional 32° C. incubation was being used.

The deviations in *counting* are shown in Table 5.

In spite of all other errors in equipment, preparation of material, technic of plating and incubation, the greatest effects observed upon the accuracy of results occurred where the proper plates for counting were not selected, the requirements of Standard Methods not being followed, or where laboratory workers failed to observe a considerable percentage of colonies on their plates, largely due to inadequate counting equipment. That this was quite common is shown in *Item 24*.

The two items marked with an asterisk and shown with large numbers in the "*not used*" column in *Item 24*, are

* DEV = Deviation; UND = Undetermined; NOT = Not Used

required only under the *Milk Ordinance and Code* recommended by the U. S. Public Health Service; hence their listing as "not used" in communities not operating under this ordinance. In many places suitable plates were not available at the time of the survey, again resulting in larger numbers in the "undetermined" column concerning duplication of counts within the tolerances listed by Standard Methods.

Finally, records were not kept as required by Standard Methods, as shown in *Item 25*. It might be mentioned that in several instances, laboratories failed to multiply correctly, and an original record of the dilution and colonies actually counted, would serve as a check on such errors. In at least 2 instances the mathematics of multiplying for a 1:100 dilution were too complicated. In one instance, in a small town for years, and in another in a metropolitan city for months, only one cipher had been used in multiplying for the 1:100 dilution.

The requirements concerning the recording of the incubation temperature used, and the reporting of plates with less than 30 colonies, were included only in the 8th edition, hence the larger numbers for these details in the "not used" column, together with one item (marked with an asterisk) required only under the *Milk Ordinance and Code* recommended by the U. S. Public Health Service.

While some of the requirements in Standard Methods may seem trivial, I believe I have seen practically every item violated sufficiently by some laboratory to influence the accuracy of the analysis.

The surveys show that each item required by Standard Methods has been adhered to by several laboratories, practically each item has been neglected by one or more laboratories. No one laboratory, at the time surveyed, had actually met all requirements in equipment and procedure, although a very few approached this. No laboratory conformed in all items of even the general group on apparatus, or technic. One laboratory conformed in preparation, one in incubation, 11 in counting, and 25 in reporting results, as shown in Table 6. This table also classifies the nature of the laboratories included in this report.

Almost universally it was the intention to follow Standard Methods, and the laboratories considered that the procedures they demonstrated conformed to Standard Methods. When the actual requirements were explained in respect to the deviations noted, and the proper equipment, technic, or procedure indicated or demonstrated, together with the reasons for such requirement; and when the probable inaccuracies of the local practice were pointed out, it was apparently the first time that a real understanding of certain requirements in

Standard Methods had been obtained. Sometimes it was true that Standard Methods had not been consulted, no copy being available, or that only an earlier edition was on hand. Several 1934 editions, a very few 1929 editions, and once or twice a 1923 edition, were unearthed. On the other hand, individuals have been known to refer to Standard Methods, and after reading the various possibilities discussed there, to do just opposite to the interpretation placed on the material by the Standard Methods Committee itself. Having witnessed the items incorrectly performed by the individual workers, the reasons for the requirements were discussed with them and a copy of the survey form summarizing the actual requirements of Standard Methods was left with them. This should result in immediate improvement in so far as technic is concerned, at least in the elimination of faulty practices not dependent upon equipment. The written recommendations made later on equipment focused attention on these deficiencies, putting this on record with the administrative officials, and indicating the basis for correction.

In size, the laboratories varied from that used once a month or so for milk analysis, to large general laboratories in metropolitan city health departments. In general, the larger laboratories were better equipped, but not necessarily so. Similarly, their technic might be expected to be above average, but in each of the largest laboratories visited, errors were made with a direct effect upon the accuracy of the results reported.

Few states have supervised to any extent laboratories within their area, and various systems have been used by the

several states doing this, ranging from voluntary action to supervision in accordance with an act of legislature. Various factors influenced the type of supervision, this probably being best where the state laboratory administrator himself visited laboratories periodically. However, such persons are usually not specialists in milk analysis, and while in general the supervised laboratories were rather uniform in equipment and procedures, vital details have been overlooked in regard to technic, and in selection of, or in reporting, results. In many states there is no reliable source of advice or consultation, and it would seem desirable to foster such a service.

It is believed the U. S. Public Health Service survey forms should be of value to administrators in improving the work of laboratories in their jurisdiction. Likewise, they should be useful as a guide to the worker in service, and should be particularly helpful to those training new workers, inasmuch as this would give all workers something more tangible to follow than, for example, the 25-30 pages discussion in Standard Methods on the agar plate method. Use of such forms should also result in the methods now standard actually being followed by laboratories; something which we assumed was being done, but obviously has not been practised.

When one considers the help that bacteriological examinations have given in the sanitary control of milk, and considers the errors of omission and commission in following Standard Methods as listed here, the possibility is evident of their being even more useful and better correlated in the sanitary control of milk when they are properly performed.

Encephalitis (Western Equine) in Manitoba—1941*

F. W. JACKSON, M.D., D.P.H.

Deputy Minister of Health and Public Welfare, Winnipeg, Canada

I KNOW it will seem to many of you like "bringing coals to Newcastle" to discuss in St. Louis the question of Encephalitis. However, following the epidemic of western equine encephalitis which occurred in 1941 in North Dakota, Minnesota, Saskatchewan, and Manitoba, we in Manitoba thought that we should carry on some experimental work in respect to the availability of a worth while immunizing agent; and, although the work in this connection is not as yet quite complete, we appreciate this opportunity of presenting certain material which we trust may be of interest and value.

Before discussing our immunization experiment we would like to give a short summary of the epidemiological features of the epidemic which occurred in Manitoba in 1941. A complete report of this epidemic will be found in

the June, 1942, edition of the *Canadian Public Health Journal*. The epidemiological summary is taken from a paper in the report prepared by Drs. C. R. Donovan, and Maxwell Bowman, both of the Manitoba Department of Health and Public Welfare. The epidemic of western equine encephalitis in Manitoba was only part of a much wider epidemic affecting the States of Minnesota and North Dakota, and the Provinces of Saskatchewan and Manitoba.

After the disease became epidemic we requested our Division of Statistics to check back on the deaths during the epidemic and preëpidemic period and learn what the general death picture looked like in comparison to other years. This survey pointed out that there seemed to be a definite increase in deaths reported from certain types of conditions, such as cerebral throm-

bosis, hemoplegia, sunstroke, and in children, convulsions. In all instances deaths reported from these causes were referred back to the physician in attend-

CHART 1
CASES OF ENCEPHALITIS AND POLIOMYELITIS - MANITOBA - 1941.
BY WEEK OF ONSET

ance for a review; and, as a result of this, the cause of death in 5 cases was changed by the physician to "encephalitis." This probably accounts in some measure for the higher case fatality rate shown for the Province of Manitoba.

There was some delay in Manitoba in the appreciation of the fact that we had an epidemic of encephalitis in the making. We believe this was more or less to be expected because we were in the midst of an epidemic of poliomyelitis when the first cases of encephalitis started to appear, as Chart 1 shows; and, many early cases were diagnosed as poliomyelitis. In checking back over our records it would appear that the true epidemic started July 16 with a case in the City of Winnipeg; and sporadic cases appeared in widely separated points between that date and August 1. Each day thereafter showed a continued increase in cases and invasion of new areas until the whole of the settled parts of the Province, exclusive of the coniferous regions, were involved. The peak of the epidemic was reached during the week of August 19, one week after the peak of the epidemic of poliomyelitis—following which there was a rapid subsidence of reported cases until the epidemic could be considered to be over on or about the middle of September.

The significant points with regard

to sex and age distribution of the reported cases are (1) a very high attack rate of infants under 1 year of age; and, I venture to say that a good many cases which occurred in this age group were not reported, probably because no physician was called, and therefore no diagnosis made; (2) a relatively low attack rate in the group which gives the highest attack rate for poliomyelitis; i.e., the age groups 1 to 20 years; and (3) a high attack rate in what might be classified as the "working-age" group; i.e., from 20 to 50 years.

Due to scarcity of labor a great many males in the older age group who had retired returned to work on the farms; and this is possibly one of the reasons why the age groups 50 years and over showed such a high attack rate. Chart 2 indicates that in every age group, excepting that under 1 year, the attack rate was considerably higher in males than in females—approximately two to one. Eighty-one per cent of the cases were in individuals of 20 years of age and over.

CHART 2
ENCEPHALITIS in MANITOBA - 1941.
CASE RATES BY SEX in AGE GROUPS per 100,000.

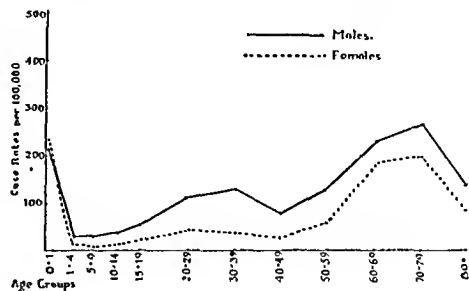

TABLE 2

Western Equine Encephalitis
Manitoba — 1941
Urban and Rural Distribution

Distribution	Number of Cases	Per cent Total Cases	Attack Rate per 100,000 Population
Urban	166	32.6	57.0
Rural	343	67.4	79.6

Table 2 shows the urban and rural distribution of cases, with percentages as well as the attack rate in each group.

Western equine encephalitis would definitely seem to be a disease of adult males in the older age groups, and adult males who work out of doors.

An attempt was made to try to estimate the prevalence of disabilities of various descriptions, both total and partial, which might result from an epidemic of western equine encephalitis.

A study of 256 cases was made in the spring and early summer of 1942, 10 months after the epidemic. Only 139 of these individuals, or 54.3 per cent, had completely recovered.

I would like to emphasize that our data are based on complaints of the patients themselves obtained through interviews by a public health nurse, or as happened in a few instances, by a letter addressed to the patient when an interview was not possible. As to the 45 per cent not yet fully recovered, I do not think we can blame the encephalitis entirely for their present condition. It must be remembered that a high percentage of them were in the older age groups and subject to the usual aging processes. However, it would appear that this disease may at least accelerate the normal aging process. Table 3 shows the disabilities complained of in order of frequency.

A case history which was brought to my attention just the day before I left Manitoba for this Conference is of interest from the standpoint of possible disabilities. Early in August, 1941, Mr. J., aged 92 years, was exposed to mosquitoes for a period of some two or three hours while sitting in his garden. This was the only occasion he had been out of a well screened house all summer. Two weeks later he developed a mild illness with some fever and mental disturbance. Recovery was complete with the exception of a certain amount of disorientation. A diagnosis of encephalitis

itis was made due to the fact his wife had definite encephalitis a few days after his illness. Mr. J. died of pneumonia on May 30, 1942. A post-mortem examination was performed and the pathologist's report, in part, reads as follows: "Microscopic sections of the pons showed small areas of necrosis and gliosis with small areas of perivascular infiltration and cuffing. Diagnosis—Active Encephalitis." This diagnosis was made 10 months after the initial infection.

Dr. Harry Medovy, Pediatrician at the Winnipeg Children's Hospital, who made a special study of the infants under 1 year of age who had contracted the disease, indicates, in a paper which has been accepted for publication in the *Journal of Pediatrics*, that, of 17 cases studied, 5 show definite evidence of disability which probably will be permanent. Dr. Medovy also reports on 2 cases of intrauterine infection of the new-born. Both mother and baby in each instance showed the onset of illness approximately 5 days after confinement. Both babies are completely spastic and will be permanently incapacitated.

One cannot leave the question of disability without giving some consideration to how such an epidemic affects an all-out war effort. Manitoba is basically

a farming community and the effect of this epidemic on this basic industry was very considerable; especially as the epidemic made its appearance at the height of the harvest season. As near as we are able to ascertain at least 200,000 man-hours of labor were lost, just at the time when they were most urgently required to harvest the wheat and other grain crops.

In respect to the Army and Air Forces it is not possible to give the number of cases or the attack rate among those young men who had joined the colors. However, we may say that since the occurrence of the epidemic over one-third of the cases which occurred in the armed forces have since been discharged as "medically unfit" to take further training.

Taking into consideration the more or less disastrous results of this epidemic—and I might say here that the casualties from it were greater than the casualties the Manitoba troops suffered as a result of the Dieppe Raid—it was thought that something should be done in order to be prepared better in case of a future visitation, which we anticipated might take place in 1942. Fortunately, our fears were not realized, as few cases have been reported. However, when the problem was under consideration the most urgent need seemed to be to ascertain whether or not the vaccine given to laboratory personnel working with the virus, was as effectual an immunizing agent for man as the vaccine which has been widely used since 1937 for the protection of horses. We also wished to ascertain the dangers, if any, of its use; and what might be expected in the way of reactions. It was decided that we would try to immunize in Manitoba a large enough group in our population, particularly in rural areas, to give us a true cross-section of the male age groups which had been the most seriously affected in the 1941 epidemic. This immunization

was on an entirely voluntary basis. Fourteen centers were selected, located principally in areas in which there were municipal doctors or salaried physicians.

The age group 21 years and over of the male population was chosen for the experiment, and in each of the 14 areas enough vaccine was distributed to immunize 50 per cent of this group. It was thought that the total group might be in the neighborhood of 3,000 persons, according to the areas and population selected. The greatest possible coöperation was received both from the public and the medical profession. If vaccine had been available and our plans had been more flexible, the total vaccinated could have been at least 5,000, as many more individuals signified their willingness to assist in this experiment than we were able to immunize. As a prerequisite of vaccination it was decided that we would obtain samples of blood from one in three of the persons being vaccinated. In all, some 1,000 pre-vaccination bloods were collected. As we had no laboratory facilities in our own province for the examination of these bloods they were examined for us by Dr. Charles A. Mitchell, Acting Dominion Animal Pathologist in the Federal Department of Agriculture, Hull, Quebec; through the kind coöperation of Dr. G. D. W. Cameron, Chief of the Laboratory of Hygiene in the Department of Pensions and National Health, Ottawa. It was found that 186 of the 926 specimens of blood examined, or 20 per cent, showed the presence of neutralizing antibodies in the individuals from whom the bloods were taken before immunization. Some 40 blood specimens of close contacts of cases were examined and the results were identical with those in this group. We believe that contact with a case, no matter how close, will not produce any immunity to the disease.

The vaccine used in the Manitoba immunization experiment was prepared

by the Lederle Laboratories and was a formalized chick embryo vaccine. Therefore, it would not appear that there should be any danger of inducing experimental infection. Our experience leads us to believe that no such danger exists, as in none of the persons immunized did any of the reactions suggest an infection of encephalitis. However, there were many mild reactions. We endeavored to obtain reports on all persons immunized and were successful in getting 1,754 reports. Table 4 gives the results of a study of the reports received.

TABLE 4
Western Equine Encephalitis
Reactions to the Administration of Chick Vaccine

Total number vaccinated (2 doses)	2,803
Total number questionnaires returned	1,754
No reactions to either dose of vaccine	768 (43.8%)
Reaction first dose—local, general, or combined	582 (33.2%)
Reaction second dose only—local, general, or combined	404 (23.0%)
Total reactions first and second dose, or both—local, general, or combined	986 (56.2%)

All evidence that we were able to obtain indicates that the reactions were not severe and did not require treatment by a physician. Certainly one is safe in saying that the reactions following the use of this particular preparation of chick embryo vaccine, although possibly more numerous, were not as severe as reactions following the use of either

scarlet fever toxin or typhoid vaccine.

The full program for the sampling of bloods taken two to three months after the second dose of vaccine is not as yet complete, so that we are only able to report on a limited number of samples which were requested by Dr. John R. Paul of Yale University, and which were examined by Drs. Albert B. Sabin and Robert Ward of the Children's Hospital Research Foundation, at Cincinnati, Ohio. We are indebted to them for permission to give this information at this time (see Table 5).

These results are in agreement with those of Beard, et al.¹ at Duke University; and with the two more recent studies by Dr. Albert B. Sabin and his assistants at the Children's Hospital Research Foundation at Cincinnati; and by Drs. Webster and Casals of the Rockefeller Institute.

We are also informed by Dr. Charles A. Mitchell of Hull, Quebec, that in a series of 25 persons immunized in his laboratory with two doses of chick embryo vaccine, 100 per cent showed the presence of neutralizing antibodies following the completion of the immunization. It is hoped that when our vaccination experiment is completed we will add to the information already available as to the value of the vaccine for the production of neutralizing antibodies. We also hope to gain some experience as to what care is required in the matter of storing and shipping bloods when no immediate laboratory

† Average neutralization index \approx 6,000+

facilities for examination are available.

We intend to continue the immunization experiments in Manitoba with the expectation that ultimately clinical evidence will become available as to whether or not the vaccine is of sufficient value to justify its distribution on a free basis to physicians and medical officers of health.

SUMMARY

1. A short synopsis is given of the epidemiological features of an epidemic of western equine encephalitis in Manitoba in 1941, which indicates that this disease has the highest attack rates in infants under 1 year, and in adult males who live and work outdoors in rural areas. Evidence is presented which suggests that sequelae may be much more prevalent than is generally supposed and indicates that further follow-up of cases is required.

2. An experimental vaccination program on 3,000 persons is discussed. The information obtained from this work leads us to believe that

a. There does not seem to be any contraindication to the use of the vaccine, and that,

although reactions may be numerous, they are not severe.

b. Two doses of the vaccine results in developing neutralizing antibodies in probably 100 per cent of persons vaccinated.

c. As yet there is not sufficient evidence available, especially of a clinical nature, to draw any conclusions as to the efficacy of the vaccine in protecting vaccinated individuals against the disease.

d. The results so far justify the continuation of experimental work in order that the clinical value of the vaccine may be ascertained.

NOTE: We would like to express our deep appreciation once again for the assistance of Dr. John R. Paul of Yale University; Drs. Albert B. Sabin and Robert Ward of Cincinnati, Ohio; and Drs. G. D. W. Cameron and Charles A. Mitchell, of the Federal Government of Canada. Without their help this report would have been impossible. We also desire to express our appreciation of the assistance received from Dr. W. G. Malcolm and Dr. Carey of the Lederle Laboratories at Pearl River, N. Y.

Comparison of the Nasopharyngeal Swab and the Cough Plate in the Diagnosis of Whooping Cough and *Hemophilus pertussis* Carriers*

JOHN J. MILLER, JR., M.D., F.A.P.H.A., CHARLES W. LEACH, M.D., T. M. SAITO, AND J. B. HUMBER

*Department of Pediatrics, Stanford University School of Medicine,
San Francisco, Calif.*

THE nasopharyngeal swab, which has been used in the past in the diagnosis of pneumonia and in the detection of meningococcus carriers, was adapted by Bradford, Slavin, and Brooks^{1, 2} to the diagnosis of whooping cough. The value of this method has been confirmed by Anderson³ and in a preliminary study by the present authors.⁴ Recently Brooks, Bradford, and Berry⁵ have reported their findings in a total of 438 nasopharyngeal cultures from 248 cases of pertussis. A somewhat smaller number of cough plate cultures were taken for comparison. Fifty-two per cent of the nasopharyngeal cultures were positive as compared to 37 per cent of the cough plate cultures. In infants under 3 years of age the difference in the results with the two procedures was most marked—32 per cent.

The following report amplifies our previous one and contains some data on the carriage of *Hemophilus pertussis* by familial contacts.

The nasopharyngeal applicator and the technic of insertion have been fully described.^{1, 4} The Bordet-Gengou medium we employed was the same as previously reported⁴ and differed from that of the Rochester workers in that

33 per cent horse blood was added instead of 15 per cent sheep blood. Fresh media were prepared every 2 weeks. It did not appear necessary to pour plates any more often. For both the cough plate and swab cultures, Petri dishes 3½ inches in diameter were used. At least two Petri dishes of medium were inoculated with each swab, and the cough plates were also usually taken in duplicate.

The cultures were obtained by many different physicians and nurses. In more experienced hands better results might be expected.

One or more duplicate tests with nasopharyngeal swabs and cough plates were made in 214 cases of whooping cough. A total of 342 comparative cultures were examined. The results are classified according to the duration of the disease in Table 1.

During the first week 74 cultures were taken. In 32 both plate and swab were positive, in 6 the plate only was positive, in 22 the swab only was positive, and in 14 both cultures were negative. Eighty-one per cent were thus positive by both or either means. It is therefore apparent that the cultural methods available for the diagnosis of pertussis in the catarrhal stage are relatively

+ Positive
- Negative

efficient. This is fortunate as of course the diagnosis can rarely be made clinically until the second or third week of coughing. As Table 1 shows, the cultural tests become less reliable as the cough persists. In every week, however, the percentage of positives obtained by swabs was higher than that obtained by cough plates. This superiority was more noticeable in the first week and after the fourth week.

The results obtained in comparative tests are classified according to the age of the patients in Table 2. As has been

40 per cent positive by cough plate. Rather curiously in the group over 10 years of age the difference in the efficacy of the two procedures was also almost 20 per cent.

When the total number of cases observed is tabulated, rather than the total number of tests, the results of the procedures appear in better light. In Table 3 are listed the results obtained in 225 cases. Sixty-three per cent were positive by swab at some time in their course (though some were not tested until the second month of the disease).

TABLE 2

A Comparison of Results with Cough Plates and Nasopharyngeal Swabs in 282 Duplicate Tests Taken during the First Four Weeks of Cough
Classified According to Age of Patient*

* The figure 282 is one less than the total (283) for the first four weeks shown in Table 1, because the age of the child furnishing one duplicate culture was unknown.

stressed⁵ the nasopharyngeal swab was particularly useful in obtaining cultures from infants. Sixty-three per cent of tests on infants under 2 years of age were positive by swab as compared to

Forty-nine per cent were positive by cough plate. Both of these percentages are of course higher than those shown in Table 1—49 per cent and 35 per cent respectively. The necessity of

TABLE 3

Results of Bacteriological Examinations in 225 Cases of Pertussis
(Many of whom were tested repeatedly though not all or always by both procedures)

Tested by Swab			Tested by Cough Plate		
Number of Cases	Number Positive	Per cent Positive	Number of Cases	Number Positive	Per cent Positive
220	139	63	219	107	49

214 cases tested by both procedures
6 cases tested by swab only
5 cases tested by plate only

repeating negative tests is therefore apparent.

It should be mentioned that the diagnosis of "pertussis" in the cases which yielded negative cultures was made on clinical grounds—typical paroxysms with or without hyperlymphocytosis. There is no doubt that atypical cases were missed by the bacteriologic tests as well as typical ones. About one-fourth of the bacteriologically proven attacks were not typical clinically. The epidemiological importance of atypical attacks of whooping cough was recognized more than 35 years ago by Luttinger.⁶ Kristensen⁷ has described the attacks in 116 children with positive cough plates as being atypical in 40 (35 per cent).

The possibility that some of the bacteriologically negative cases we observed might have been para-pertussis should be mentioned. However, this is not very likely as we are familiar with the cultural characteristics of *Bacillus para-pertussis*.^{8, 9} It grows faster and more luxuriantly on Bordet-Gengou medium than does *H. pertussis* and hence is less likely to be missed if it is considered.

During the course of this study, a period of 2½ years, 5 strains of *B. para-pertussis* were isolated. (The cases are not included in Tables 1–3.) Three of these strains were recovered within a period of 1 month from widely separated parts of San Francisco. Only 2 of the 5 strains came from children with typical clinical whooping cough.

In 3 instances the coughing was less severe, of short duration, and not clinically diagnosed whooping cough. Both nasopharyngeal swabs and cough plates were positive in 2 cases, swabs only were positive in 2 cases, and only the plate positive in 1 case. No positive cultures were obtained after the 14th day of the attack (3 children had stopped coughing by then).

It is our impression that whereas *B. para-pertussis* infections are probably quite common in this community—40 per cent of 50 children with negative histories were found to carry specific agglutinins,¹⁰ this organism probably causes only a small minority of the cases of typical whooping cough. That still other organisms may be occasionally responsible for this syndrome is likely. Brown described a typical case associated with *Bacillus bronchisepticus*,¹¹ apparently communicated from a rabbit with snuffles. Alexander¹² has noted that occasional cases of chronic bronchitis, difficult to distinguish from whooping cough, may be due to infections with *Hemophilus influenzae*. Furthermore, we have occasionally found almost pure cultures of this organism on nasopharyngeal swabs or cough plates. It is not possible to say whether these were cultures of the etiologic agent or of a secondary invader. We did not type the cultures. However, Sinclair¹³ and Alexander¹⁴ have conclusively shown that *H. influenzae* type B is a dangerous respiratory pathogen in infancy. In any evaluation

of the diagnostic procedures under discussion or of the prophylactic effectiveness of *H. pertussis* vaccine, the possibility that apparent failures are due to infections with other organisms than *H. pertussis* must always be borne in mind.

Fifteen familial contacts, without cough or hoarseness, were cultured during the course of this study. The results of these tests are shown in Table 4. Three were contacts to cases of para-pertussis and the remainder to cases of pertussis—all bacteriologically

and Blatt and his coworkers¹⁵ first described asymptomatic contact carriers.

This evidence complements the epidemiologic evidence that healthy carriers exist. Their importance in the epidemiology of pertussis, however, is uncertain. Our carriers were certainly transient carriers and, without cough, they probably disseminated but few organisms. To the writers it would seem that mild and atypical cases, particularly in adults, together with early undiagnosed cases, probably are more important.

TABLE 4

Asymptomatic Familial Contacts to Cases of Pertussis and Para-pertussis

* Coughs were induced by placing swab in nasopharynx

H. pert. = *H. pertussis*

B. para. = *B. para-pertussis*

proven. Two were infant siblings of children with pertussis and were injected with immune pertussis sera with prophylactic intent. Neither infant developed a cough and 4 repeated swabs on each child yielded negative cultures. Of the remaining 10 uninjected familial contacts to pertussis, *H. pertussis* was isolated by induced cough or by swab from 3. One of these 3 carriers was incubating the disease as he began to cough 3 days later. Kristensen⁷ has described 9 similar incubatory carriers,

Isolation of the typical cases, undiagnosed until paroxysms have appeared, is certainly of limited value. The more widespread use of bacteriologic procedures to identify early cases, atypical cases, and carriers is therefore advocated. Nasopharyngeal swab cultures, more practicable and more productive than cough plates, should be given a trial in public health laboratories.

SUMMARY

Three hundred and forty-two com-

parative tests with nasopharyngeal swab cultures and cough plates were made in 214 cases of whooping cough. In every week of the disease, and in each age group the swabs yielded a higher percentage of cultures positive for *H. pertussis* than did the cough plates. The use of both procedures however was superior to that of the swab alone. Five cases of para-pertussis were encountered during the course of the study. Three carriers of *H. pertussis* were found among 12 familial contacts to pertussis.

The nasopharyngeal swab technic can provide the public health officer with a relatively simple means of detecting early cases, atypical cases, and carriers of *H. pertussis*.

TUBERCULOSIS, INDUSTRY, AND YOUNG WOMEN

RECENTLY in an inaugural address as President of the National Tuberculosis Association, Dr. Lewis J. Moorman, of Oklahoma City, called attention to the tuberculosis hazards in the present situation where thousands of young women are going into industrial work. Dr. Moorman's address was scholarly rather than dramatic, and consequently did not catch the attention of the newspapers. He is, however, a sane and competent authority in the tuberculosis field and his anxiety as to what may happen is one which all public health workers should share, and share sufficiently to institute every possible measure for prevention and control in the situation which exists.

If one studies a graph which sets forth age-specific death rates for tuberculosis, it is noted that following a low mortality point in the age group 5-14 years, there is a steady rise in the death rate with each succeeding decade, so that in ages 65-74 years in 1940 in the United States the death rate from tuberculosis was 81 per 100,000 population as against 38 in the 15-24 age group, and 56 in ages 25-34. Assuming equal completeness and accuracy of reporting in the age groups concerned, one is justified in saying that in any given 10 year period, an individual 65 years of age is much more likely to die of tuberculosis than would be the case with one in his early 20's. This knowledge is exceedingly important from an epidemiological standpoint. It has made public health workers realize that elderly persons not infrequently serve as foci of tuberculous infection, and it has given a new insight into the natural history of the disease. At the same time, however, a consciousness that the highest tuberculosis death rate is in the elderly has tended to blur the fact that, because there are so many more younger people than there are older ones, a low tuberculosis death rate in young adults will produce a much greater number of deaths than a high tuberculosis rate in persons 65-74 years of age. Thus, although in 1940 the death rate from tuberculosis in persons 65-74 years of age was more than twice that in persons 15-24 years of age, the number of deaths from tuberculosis reported for that year was nearly twice as great in the young as in the old. An even greater number of deaths from tuberculosis in 1940 was in the 25-34 age group. So strong is the force of mortality from tuberculosis among comparatively young

persons that although, in the mass, tuberculosis ranks about seventh in a list of mortality from all causes, it is the leading cause of death in persons from 15 to 34 years of age.

It should be borne in mind, too, that the mortality curve in females reaches its high point (except for very elderly females) much earlier than is the case with males. The curve for the latter rises fairly evenly with age; the curve for the former climbs rather abruptly and tends to remain somewhat horizontal. Out of the fields of general physiology and pathology there have come bits of knowledge which throw some light on this sex differential, and it is a matter which deserves continuing scientific study. But one need not wait upon an explanation to appreciate the fact that young women offer a higher tuberculosis risk than young men; nor need one wait upon additional knowledge when it is already evident that the industrial worker in general has a higher tuberculosis mortality rate than has the white collar group. Today and now, the facts to face are that war's necessities are pushing one high rate group into the working and living conditions of another high rate group; and unless every possible precaution is taken, the complex and diverse factors which contribute to the high rates in these respective groups may act and react upon each other to the jeopardy of the human beings concerned. Obviously, the situation has within it all the elements of an epidemic (or high endemic) potential.

Although the tuberculosis hazard in industry, to the young and especially to young women, is recognized by the U. S. Public Health Service, by the National Tuberculosis Association, by various state and local health departments, and by many others concerned, it is not at all appreciated by young women. Actually, girls going into industry tend to believe that they acquire ruggedness by virtue of donning pants and getting their faces dirty. This attitude calls for sound and far-reaching instruction as to diet, rest, the danger of time-and-a-half and double time. It calls, too, for properly managed plant cafeterias and proper plant ventilation, for good public health nursing in the industrial community, for sound medical advice. In fact, it demands all those measures included in a good industrial hygiene program, including careful preplacement examinations and periodic x-ray surveys.

Tuberculosis has been present for so long and people are so accustomed to it, that the interest of the public and of many public health workers is in danger of being sidetracked to more glamorous and exciting problems. This is a serious deterrent to accomplishment in this field. Further, the decline in tuberculosis, both in morbidity and mortality, in the last 40 years, may lead some to think that the problem is one of the past. Let there be no mistake in this direction. Tuberculosis continues to be a real problem. If, instead of comparing the tuberculosis rate of today with what it was 50 years ago, one will compare the tuberculosis prevalence and mortality of today with today's prevalence and mortality of other diseases, the present seriousness of the tuberculosis problem can be appreciated: In the most productive period of life, tuberculosis continues to cause more deaths than any other one disease.

TERMINOLOGY IN HUMAN MALARIA

IT is generally accepted that human beings are subject to infection by three, perhaps four, species of malarial organisms. These are *Plasmodium vivax*, *P. malariae*, and *P. falciparum*, with *P. ovale* somewhat recently described as

a separate species. Further, the diagnosis and epidemiology of these different types of infection have been fairly well worked out and current research gives promise of sound advances in treatment and control. However, in the matter of terminology there still exists rather a distressing lack of uniformity, disturbing to those particularly interested in malaria and probably confusing to medical students and casual readers of texts, monographs, and papers on this subject.

This lack of uniformity in terminology of malaria probably arises because the disease is an old one and the development of knowledge has been piecemeal. One of the earliest clinical designations was in relation to the continuity or lack of continuity of fever, and to express these differences one finds, particularly in the older literature, reference to *intermittent* and *remittent* malaria. Similarly, clinicians have used terms to indicate the severity of a given case of malaria, as *benign*, *malignant*, and *pernicious malaria*. Attempts have been made too to suggest certain aspects of a given illness in terms of some outstanding symptom, as *cerebral malaria*, *hemorrhagic malaria*. This sort of terminology has always been frowned upon by those interested in precise nomenclature, and has nothing to commend it.

Perhaps the terminology in most common usage relates to the periodicity of paroxysms, as *tertian*, *quartan*, and *quotidian* malaria. This method of designating the various forms of malaria is as old as Hippocrates and has the advantage of wide acceptance. It is not, however, satisfactory for, while malaria caused by *P. malariae* usually manifests quartan periodicity, frequency of paroxysms may not in all instances be correlated with a particular type of malarial organism. To complicate the matter further, the term *subtertian malaria* has been developed. This connotes a type of malaria with a tendency toward every-other-day paroxysms but with some divergence from that periodicity. As ordinarily employed, it indicates a falciparum infection. This is a particularly unfortunate term, especially where, in a given paper, one finds *malignant tertian* and *subtertian* used synonymously in the same paragraph. Some of the outstanding authorities on malaria are guilty of such usage and juxtaposition. Disturbing, too, is the fact that many who ought to know better speak of *tertian*, *subtertian*, and *quartan organisms*. This, of course, is inexcusable.

Another term not infrequently found in clinical texts and in the older writings is *estivoautumnal malaria*, or *estivoautumnal organism*. This again refers to the falciparum type. It bears no relation to etiologic, pathologic, or even symptomatologic terminology, but arises mainly because in many areas the environmental conditions necessary for the development of this type of infection tend to occur most often in the late summer and early autumn. Finally one encounters a terminology built upon an etiologic basis. Out of this come the designations *vivax malaria*, *falciparum malaria*, and *malariae malaria*. Dr. Mark Boyd, at the Philadelphia meeting of the American Association for the Advancement of Science (December 30, 1940-January 1, 1941), recommended that, for precision, human infections be designated by the name of the causative parasite, but suggested that for euphony the term *quartan malaria* be substituted for *malariae malaria*. Another authority which would substitute etiological designation for terminology now in current use, is the 1942 Edition of the *Standard Nomenclature of Diseases*. *The International List of Causes of Death*, however, adheres to clinical designations and would have all deaths from malaria reported as either benign tertian, quartan, tropical (malignant) tertian, or "other or unspecified malaria." Strange to say, the *International List*, in the index, does not even

carry the terms *falciparum*, *vivax*, or *malariae*; and stranger still, indicates *subtertian malaria* as properly reportable under *benign tertian*.

Inasmuch as malaria is one of the important, perhaps the most important of the tropical and subtropical diseases and, in view of the fact that we shall in the future be learning more of it, if not suffering more from it, it is highly desirable that there be adherence to uniform and consistent nomenclature. It would seem sensible that all individuals and agencies bend their efforts toward adoption of the etiological terminology. Unless one does this, precision is out of the question; and although it is recognized that *malariae malaria* is a clumsy term, we should not be inclined to sacrifice consistency to euphony. Fortunately, it is not a term that will have to be used very often, and, at that, it is not nearly so clumsy as *Rickettsia prowazeki prowazeki* or *Rattus rattus rattus*, both of which manage to find their way into print if not into decent conversation.

As an editorial policy, the JOURNAL will in the future attempt to be consistent in this matter and, so far as nomenclature is concerned, will bluepencil all terms not in conformity with a terminology based upon etiology.

THE Editor has just received from the Surgeon General of the U. S. Public Health Service a very welcome communication bearing upon the recently held United Nations' Conference on Food and Agriculture. This summary, the Surgeon General tells us, was prepared at his suggestion by Dr. William H. Sebrell. Believing that JOURNAL readers will be interested in this analysis and interpretation of the Food Conference by an outstanding authority in the field of nutrition, the communication is published below. The caption was chosen by Dr. Sebrell, and because of its significance, is included.

THE MARRIAGE OF PUBLIC HEALTH AND AGRICULTURE

A new and higher level of health for all mankind is the hope which springs from the United Nations Conference on Food and Agriculture held at Hot Springs, Va., May 18 to June 3, 1943. The Conference declared its conviction that this hope can be realized through improved nutrition, and recommended that every nation accept as a prime obligation the adaptation of its national and international policies to this end.

The growing recognition of the prime importance of nutrition in health has gone hand in hand with the development of the science of nutrition. Practically all of what may be called the modern knowledge of nutrition has developed during the present century

and much of it since World War I. The discovery of the many vitamins, recognition of the great physiological importance of the various mineral salts, and the development and use of better methods for the diagnosis of deficiencies have made the entire world increasingly aware of the enormous amount of ill health, poor development, suffering, disease, and death due either directly or indirectly to malnutrition.

International attention was first focused on the problem by the activities of the League of Nations beginning in 1925, culminating in the reports of the "Technical Commission on Nutrition" and the "Mixed Commission" on nutrition in 1937. Ever since that date, nutritional knowledge has advanced so

rapidly that in 1942 our own Food and Nutrition Board of the National Research Council was able to draw up a new and more complete set of recommended dietary allowances for optimum nutrition. Several world prominent physicians and scientists in the field of nutrition participated in the Conference, and data presented brought out that, measured by the National Research Council yardstick, much of the world's population is subsisting on inadequate food, and that, in terms of adequate food for everyone, not only has no real food surplus ever existed but the world has never had enough to eat.

The Conference stressed the importance of full collaboration between agricultural and health authorities indicating that the latter must play a prominent part in the guidance of the program for better nutrition.

The revolutionary ideal which met with unanimous acceptance at the Conference was that it is one of the primary responsibilities of the state to see that its population has an opportunity to obtain a food supply adequate for health, and that agricultural policies both national and international must be directed toward this end. Recognizing that the immediate attainment of such a goal is out of the question for most nations, it was proposed that each of the 44 nations represented should immediately initiate nutrition programs designed to bring about pro-

gressive improvement in national diets, giving special attention to the nutrition of the most vulnerable groups in the population such as low income groups, infants and pregnant and nursing mothers. To attain these goals, national nutrition organizations were recommended for each country. In order to attack the problem effectively, it was pointed out that in addition to dietary survey data, health and medical surveys are necessary, using the newer clinical and laboratory methods both for assessing the state of nutrition and determining the prevalence of gross deficiency diseases.

In addition to such national activities, an international interim commission was recommended to be followed by a permanent organization for the purpose of collecting and disseminating research data and statistical information and for giving technical assistance where requested. Basic considerations necessary for the success of these plans but beyond the scope of the Conference are guarantees of peace and national security which have greatly influenced agricultural policy in the past.

It is obvious that if the world's agriculture can be based on freedom from want of food for all peoples in all lands, we can have an era not only of economic prosperity but also of health prosperity such as the world has never seen. The success of the deliberations of the United Nations Conference is a first step on this new pathway.

REPORTS OF COMMITTEES

The By-Laws of the American Public Health Association provide that no standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council. Except where specifically noted to the contrary, the following reports are in the nature of progress reports from committees, most of which have had Section approval, but which have not been presented for Governing Council action, and therefore are not to be interpreted as standards approved by the American Public Health Association.

Pneumoconiosis

Industrial Hygiene Section

ALTHOUGH the silicosis problem is not now attracting the attention it received a few years ago, its control and the control of dust in industry are still live subjects. According to a recent issue of the Ohio Industrial Commission *Monitor*,¹ occupational disease experience in Ohio continues to show a substantial increase in compensation claim cost, and revision upward in the occupational disease rates has been required in 76 industries. This upward revision is particularly pronounced in industries where dust diseases are prevalent.

In view of the possibility of increased incidence of dust diseases among coal miners as a result of accelerated production to supply expanding industrial requirements for coal, the recent publication by the British Government of the Medical Research Council's report² dealing with conditions in the South Wales coal fields is of considerable interest, as it calls attention to the pneumoconiosis hazard among soft-coal miners. There has been much controversy in England regarding the pulmonary condition found among the South Wales coal miners; some investi-

gators claim that the condition is not silicosis. The definition of silicosis (based on the classification adopted at the International Conference on Silicosis in 1930) as applied to compensation schemes in Great Britain at present is "fibrosis of the lungs due to silica dust." This standard of diagnosis requires for compensation pulmonary disability and definite nodulation or consolidation as revealed by x-ray examination. According to the Council's report, strict adherence to this definition has prevented the compensation of bituminous-coal miners suffering from disabling pulmonary disease, apparently of occupational origin. The Committee on Industrial Pulmonary Disease that made the medical study in the South Wales coal fields stated that, although there are certain distinctions between the pulmonary abnormality found typically in colliers and that found typically in hard-heading workers, it is impracticable to differentiate between them in routine work. Much importance is given in the report to pulmonary changes that up to the present have not been considered a cause of disablement. On the basis of the x-ray

COMMITTEE ON PNEUMOCONIOSIS

Published reports: *Year Books* 1931-1932, 1932-1933, 1933-1934, 1935-1936, 1941-1942.

findings, the cases were grouped as (1) normal, (2) reticulation, and (3) consolidation, subdivided into nodulation and more advanced stages. According to the investigators, as regards associated frequency and degree of respiratory disability, "reticulation" occupies a position intermediate between normal and consolidation, not much below the nodulation subsection of the latter, but much below the more advanced stages of consolidation. The report stated that—

Reticulation appears to indicate a condition of the lungs which may cause respiratory disability, but this occurs mainly in middle-aged and older men. As a corollary, a fairly considerable proportion of men showing reticulation will have no detectable disability—as will also some men with nodulation. In fact, only in the men with most advanced changes is there full agreement between the x-ray changes and the clinical evidence of disability.

The recommendations of the committee include the following:

1. New terminology. "Pneumokoniosis in coal workers"—this to include reticulation even in the absence of other x-ray changes, and to cover all coal workers, whether on the surface or underground.

2. Existing criteria of diagnosis to remain:

- (a) Positive x-ray findings of a definite character;

- (b) Presence of disability.

3. A warning against neglect of hard headings and mention of certain preventive measures. The main aim must be to reduce dust created at the coal face.

4. Initial and periodic examination considered desirable.

In summing up the report of the Silicosis Research Committee, Dr. T. W. David of the Amalgamated Anthracite Collieries stated:

The industry is now faced with pneumokoniosis affecting large numbers of workmen, many of whom in the later decades of life may be materially disabled by cough and shortness of breath. It is proposed to make this condition compensatable. The effect of this will be, particularly when collieries shut down, that claims to compensation will be

greatly increased and that many cases will be included for compensation when any disablement, possibly only doubtfully due to the lung condition, can be put forward. Regulation regarding environmental conditions, possibly methods of mining, and certainly dust suppression, will be put forward, adding materially to the present arduous task of the colliery manager.

A system of initial and periodic medical examination will be an essential development and a high standard of physical fitness should be demanded. One highly desirable effect will be the exclusion of infective cases from the mines. Apart from its necessary impact on the question of labour supply, this measure will create a large social problem. Firstly, there will be the problem of treatment of disabled workmen, particularly in those cases where there is an element of infection. Secondly, there will be the vast problem of providing employment for suspended workers with little or no disability. At first the number of these is likely to be large, and provision for them will demand considerable effort and organisation.

It can be seen, then, that the difficulties which will be raised by pneumokoniosis in coal workers are likely to be great and varied, and their solution will demand action on a scale which will be beyond the resources of the industry itself.

Studies made in an anthracite and two bituminous-coal mines in the same district in Russia³ yielded results somewhat similar to those obtained in the South Wales coal fields and in the United States. According to the Russian studies, miners in the anthracite mines were affected by more serious forms of pneumoconiosis, that limited their working capacity, than were miners in bituminous-coal mines. The limitation of working capacity among anthracite miners was determined mainly by emphysema and myocardial damage. One of the main points of interest in the results of the Russian investigation was the contrast in incidence of pneumoconiosis between the anthracite and bituminous miners examined from the same region. After reviewing the many and very variable factors in the Don collieries that might affect the recorded amount of pneumoconiosis at

a particular mine—the method of mining, the geological and hygienic features and concentration of dusts in a mine, the length of employment of the men, and the departure from the mine of the unfit—the investigators concluded that the contrast in incidence is genuine, and that pneumoconiosis, as an occupational disease, is to be particularly considered in connection with anthracite mines; such mines therefore require radical measures for the reduction of dust. One of the causes of the difference in reaction of the two types of miners is thought to be the physical properties of anthracite dust, which has a more noxious effect on the lungs than the dust from bituminous coal; the work of several Russian authors is quoted in support of this suggestion.

In the anthracite colliery investigated, pneumoconiosis was found in 11.1 per cent of the men, while in the two bituminous collieries the incidence was 3.3 and 2.3 per cent, respectively. Comparing one mine with another by periods of service, there was little difference in the younger employment groups; in men of more than 20 years service, however, an excess was evident in frequency and in degree of pneumoconiosis in the anthracite mine over the two bituminous mines; the percentage affected in this employment group in the anthracite mine was 27.1 and in the two bituminous-coal mines 13.5 and 11.0 per cent, respectively.

Although comparison of data obtained under conditions that probably are not comparable is of questionable value, the apparently rather close agreement of the figures showing the occurrence of silicosis or anthracosilicosis in certain coal fields of Russia, England, and the United States is interesting. According to the studies in a Pennsylvania anthracite mine, 23 per cent of the miners examined were affected by anthracosilicosis.⁴ In anthracite mines in the South Wales coal fields,⁵ 18.7

per cent were affected, while the figure obtained in Russia was 11.1 per cent. Silicosis was not found in the South Wales coal fields among bituminous-coal miners who had worked fewer than 10 years in the mines. In those who had worked 10 to 20 years the incidence was 3.5 per cent, and in those who had worked more than 20 years it was 3.2 per cent. The incidence in the anthracite mines was 3.9 per cent for those employed fewer than 10 years, 18.6 per cent for those employed 10 to 20 years, and 29.0 per cent for those who had worked more than 20 years. The percentage for all the bituminous-coal miners examined in Utah was 3.2 per cent, while for underground workers it was 4.6 per cent. Anthracosilicosis was not found among Utah bituminous-coal miners who had worked fewer than 10 years; however, the incidence of the disease rose from 1.7 per cent for those employed 10 to 19 years and 5.1 per cent for those employed 20 to 29 years, to 22.5 per cent for those employed 30 or more years. The incidence of anthracosilicosis for the anthracite mines of Pennsylvania cannot be compared with that for the South Wales mines, as data for the former are grouped according to amount (dust concentration) as well as period of exposure.

Another interesting report of pneumoconiosis among coal miners, by Dr. R. Harold Jones of Fairmont, W. Va., was published recently in the *Journal of the American Medical Association*. Dr. Jones stated⁶ that several years ago he and his colleagues were impressed with the number of soft-coal miners who presented themselves at the Laird Memorial Hospital with a major or a minor symptom of chronic cough or dyspnea, usually referred to by the patient as "miners' asthma." Dr. Jones and his colleagues became interested in these cases and obtained a careful history, especially with regard to indus-

trial aspects. During a 4 year period, 86 cases of silicosis were discovered in which silicotic changes were present in varying degrees. Only those cases with exposure to dust in bituminous-coal mines alone are discussed in Dr. Jones's report. He stated that in this study he had attempted to show that silicosis in soft-coal miners is not a rare disease, that "miners' asthma" and anthracosilicosis are one and the same, and that the entity can be detected by searching clinical study of persons employed as underground workers in the mining and preparation of bituminous coal. Although it has been demonstrated that the greater number of cases occur in the decades from 40 to 60 years of age, and that most of those disabled by anthracosilicosis are in this span, four men in the next younger decade (30 to 39 years) were disabled. All of those in the disabled group had spent a large part of their mining life as drillers, motor runners, coal shooters, or machine men. These occupations appear to be the most hazardous from the viewpoint of exposure to siliceous dust, to the extent of causing disability. He concluded that disability is not necessarily proportionate to the total number of years employed in the mining industry but depends more on the occupation. However, a lesser but definite degree of anthracosilicosis does occur, although not to a disabling extent, in loaders and other underground workers after long years of employment.

Post-mortem studies revealed two types of pneumoconiosis in soft-coal miners—the normal deeply pigmented lung, with definite changes of associated silicosis resulting from long years of exposure to bituminous-coal dust containing silica, and advanced conglomerate pulmonary silicosis with a minimum of anthracotic pigment.

The following statement by Dr. Jones would seem to indicate that considerable work remains to be done on the

subject of pneumoconiosis and that a profitable field for investigation might be the bituminous-coal mines of the United States:

Unfortunately, little work has been done on group surveys of underground workers in the bituminous-coal industry. Before a definite impression can be had as to the real incidence of silicosis and anthracosilicosis in these workers, systematic studies of large groups in the soft coal fields will have to be carried out. At the same time, information regarding dust hazards as determined by thorough engineering surveys is almost completely lacking. Before worth while statistics become available showing the actual incidence and degree of silicosis and the hazards due to bituminous-coal dust containing silica in the bituminous-coal industry, thorough industrial engineering and medical surveys in the various fields must be made and the results of the two correlated.

Mention might be made of the apparent tendency to lower somewhat the standards formerly set as a safe concentration for exposure to various types of dust. The tentative standard of 5 million particles per cubic foot of air for dust, irrespective of its silica content, seems to have been too high according to results of some more recent studies. In a discussion at the Fourth Saranac Laboratory Symposium on Silicosis, Dr. Gardner⁷ stated that, although the maximum permissible dust concentration in iron mines is 5 m.p. per cu. ft. of air, as the rock contains as much as 50 per cent silica it has been assumed that it would be safer to impose the use of masks than to experiment upon the men with the possibility of producing silicosis after 20 or more years of employment.

From data on the relationship of silicosis to dust concentration obtained from a study of silicosis and lead poisoning among pottery workers, which showed clearly that even moderately severe cases of silicosis occur at relatively low concentrations of dust, the Division of Industrial Hygiene of the National Institute of Health⁸ con-

cluded that if the dust exposure could be brought below 4 m.p. per cu. ft. new cases of silicosis would not develop.

Clifford S. Gibson,⁹ Engineer and Secretary of the Technical Silicosis Research Committee of the Ontario Mining Association, stated recently that the general aim in Ontario is to reduce the dustiness of the air to the lowest possible limit. Although 300 particles per ml. has sometimes been considered a safe limit, the tendency recently has been to reduce this to 200 particles per ml., and it is significant that in an industry with air-borne dust containing up to 29 per cent of quartz, dust control measures installed have reduced dust counts to 50 to 100 particles per ml. around some operations. Such provisions would not have been made if they had not been thought necessary.

Check Anthrax—A Warning and a Plea*

Industrial Hygiene Section

IN 1938 we brought the review of the literature on anthrax up to date. In 1939 we presented a "Twenty Year Survey of Anthrax in the United States," which embraced all the previous statistical reports we had made and covered the experience in this country for the period 1919-1938. We hope to make a 5 year report for comparison in 1944. It is being brought to our attention that there is an alarming increase in anthrax in this country, particularly in the wool industry, and last year we made a brief report on the experience of Philadelphia as indicative of that of the rest of the country, particularly in those places where wool industries are located. We brought to

years prior to that time, mentioning 7 cases in one mill in 3 months. Because of the increasing seriousness of this situation and the excellent coöperation of Dr. P. F. Lucchesi, Acting Chief of the Division of Communicable Diseases of the Philadelphia Department of Public Health and Superintendent of the Philadelphia Hospital for Contagious Diseases, in supplying complete and reliable statistics for the City of Philadelphia, we have felt it advisable again very briefly but emphatically to call your attention to the status of this problem in the city as an indication of the larger problem we are facing in the country as a whole.

Table 1 illustrates this trend.

TABLE 1
Anthrax Cases in Philadelphia by Sources of Infection

your attention at that time the concern of the States of New York, New Jersey, and Pennsylvania regarding this situation. This year we have received a query from the State of New Hampshire, which at the time of our last statistical report had had no cases for 10

It is readily evident from this table that the incidence of anthrax has almost trebled since the beginning of the present war and that it is still increasing. It is also evident that while the number of tannery cases in relation to the total number of cases has *decreased* by more

* Report of the Committee on Industrial Anthrax.
COMMITTEE ON INDUSTRIAL ANTHRAX

Organized 1924. Published reports. *A.J.P.H.* Nov., 1924, Jan., 1926, Feb., 1930, *Year Books* 1934-1935, 1939-1940, 1941-1942. The two most informative reports, while not published, were mimeographed for distribution by the U. S. Public Health Service—reports of Oct., 1938, and Oct., 1939.

than 57 per cent, the number of cases due to wool has *increased* approximately 90 per cent. We have pointed out in many of our past reports that, until England opened her wool-disinfecting station in 1921, wool anthrax in this country was almost negligible (3.2 per cent of the total number of cases for the 5 year period 1919-1923 as compared with 27.2 per cent for the 5 year period 1929-1932), and that the increase was due to the deflection of inferior wools to this country where disinfection charges need not be paid.

The sources from which the infective materials were obtained have been recorded in every case in Philadelphia, at least since 1932. Unfortunately it is extremely difficult, especially in bales of wool or hair, to select specific samples for analysis which actually contain the organism, so that all materials used at the time of onset of the case must be regarded as suspicious. These materials came from widely distributed geographical areas, including South American, African, European and Asiatic countries, and were so hopelessly mixed that no particular source could be singled out as being the point of origin of any given case or group of cases. However, in replies from 49 countries in these continents to questionnaires sent out in 1939, we obtained information showing that both animal and human anthrax were decidedly widespread, and indicating that there might be good reason to suspect almost any of the materials listed. In many of our previous reports, we have pointed out the worthlessness of consular certification to the effect that areas from which such materials are shipped are free of anthrax. In peacetime the skin or wool from one animal in a whole bale might be infected while in wartime, as happened in the last war, materials which cannot readily be moved remain piled on docks, become

soaked, and eventually permeated with anthrax from the one skin or fleece, thus increasing many fold the possibility of the final handler's becoming infected from the single originally infected animal. Undoubtedly the longer the war continues and the longer the elapsed time between the death of animals and the importation of their products to this country, the greater will become the increase in wool anthrax. This holds equally true of goat skins, but the reduction in tannery anthrax during this period might well be due to the reduced use of goat skins for fancy shoes, and the increased use of packer-killed-cattle hides for the more durable shoes. We may very well expect that, with the close of war and a return to greater use of imported goat skins in the tanneries—skins which have been long in reaching their ultimate destination—we shall again see an increase in tannery anthrax as well as in wool anthrax.

In our 1939 report we pointed out the definite trend toward increased agricultural anthrax in this country. This does not of course show in our Philadelphia figures and we have not collected figures since that time to show whether this trend is continuing, but you will remember that in each successive 5 year period a greater number of states reported anthrax cases, and that the percentages of agricultural cases to the total number of cases in the four 5 year periods showed a progressive increase—namely 13, 14, 26, and 34 per cent.

It is regrettable that with such a situation so few of our state departments of health take an active enough interest to collect complete information on all such cases or to act in preventing a further increase. It is still more regrettable that the U. S. Public Health Service has ceased to make anthrax in this country reportable to them. That

action in itself has given state authorities and others the impression that it is no longer of sufficient importance to be considered. While it is true that the total number of cases and deaths in any one year from this cause is small compared with that from some other conditions, it is also true that it can become a much greater menace if not checked. Although our present incidence in Philadelphia is less than 2 per 100,000 population, that for Chile, for instance, in 1938 was 12 per 100,000 population, with a fatality which had increased from 6 per cent in 1920-1924 to over 20 per cent in 1938. And we have sufficient evidence from early times that it is not impossible for this malady to assume the proportions of a plague. By way of comparison, taking figures at random from the *U. S. Public Health Reports* for September 4, 1942, the average 1937-1941 incidence for both diphtheria and typhoid-paratyphoid in the 89 registration cities was slightly over 9 per 100,000 population, and Pennsylvania states her poliomyelitis incidence in 1941 to be less than 8 per 100,000 population; yet authorities throughout the country are keenly awake to these hazards and are doing all in their power to keep them down.

We do not want to lose sight of the definite desirability of the establishment of government controlled disinfecting stations, for wool and hair at least, at ports of entry, such as England has so successfully operated. We realize, however, that with the present war emergency we have no hope of immediate action in this direction and that the best we can do for the present is to bring the situation emphatically enough before local health authorities and the industries themselves, so that they will be alert to their own problems and take whatever action they can to check or lessen the anthrax hazard in their own locality. In the case of wool

and hair industries, it is not out of the question to adapt the English method of disinfection in combination with wool scouring, without much additional equipment. One mill in New Hampshire is already preparing to do this experimentally upon our advice. Of course it will add to the expense of wool processing and will not be so kindly received by manufacturers who are not made to realize the hazard involved. But, lacking any satisfactory method of disinfection nearer the source of supply, mills in which cases recur—and there have been 4 of these in Philadelphia alone in the last year—should afford to take this precaution. Wool, as processed at present, can remain infective throughout, as evidenced by cases in handlers of finished products only, so that disinfection as soon as it enters the plant, or before it enters the plant if scoured wool is obtained from elsewhere, should do much to lessen this hazard. Our present methods of so-called disinfection for wool do *not* disinfect, as we have pointed out before.

With the tannery problem it is more difficult to offer specific suggestions, but it is a problem which should be given serious consideration, with enough research being backed by private or government agencies to develop a satisfactory method for skin disinfection which could eventually be applied to government disinfecting stations at ports of entry or, better still, at ports of shipping. As we have said before, no method economically within reason which will adequately disinfect and at the same time completely satisfy the manufacturers' requirements for a tannable skin, has as yet been developed. The Schattenfroh method is fairly adequate and has been found satisfactory to some Europeans, but it is rather expensive, and some of our American tanners complain of its effect on the

skins. The Lehmann method is adequate and satisfactory only if the skins are tanned at once, since it softens them too much if they are left for some time before being tanned. Our experimental iodine disinfection, when tried out on a semi-plant scale, did not prove satisfactory without the addition of potassium iodide, or unless the iodine was in colloidal form, which makes this method entirely out of the question financially. And of course, as we have so often previously stated, the government recommended lime-soak and bichloride methods are entirely inadequate.

While the solutions of the problems of wool and tannery anthrax are primarily in the hands of state and federal health and labor agencies, that of agricultural anthrax is more in the hands of the U. S. Bureau of Animal Industry and state departments of agriculture, who, as often happens, are more awake to the problems of saving animals from this hazard than our health authorities are to that of saving human beings. The weapons of attack here are greater insistence upon prophylactic inoculations of herds and flocks in areas where the disease has been known to exist, and not only increased activities in insisting upon proper disposal of carcasses of animals dying of anthrax, but particularly education of farmers, sheep men, and cattle handlers, in recognizing such carcasses so that they will not autopsy them to deter-

mine the cause of death, as has so often happened.

Just a word concerning the treatment of cases once they have developed. Of the 26 cases treated in Philadelphia in the 12 month period, September, 1941, through August, 1942, 17 received serum alone or in combination with other treatment, and 19 received neoarsphenamine alone or in combination with other treatment. We mentioned last year that we had no record of any fatality in this country in an anthrax patient treated with neoarsphenamine. The first exception to this statement has occurred this year in Philadelphia with 2 fatalities, one of which, however, was a pulmonary case which had been treated for 2 weeks as a pneumonia patient before an anthrax diagnosis had been made and serum and neoarsphenamine administered. We are coming more and more to feel that neoarsphenamine is the treatment of choice, especially since it can always be readily available.

In closing, I wish to make a strong plea that we do whatever may be in our power to awaken authorities to our increasing anthrax hazard, and to stimulate them into sufficient interest and activity to check this hazard now, before it approaches the major hazard class.

Ventilation and Atmospheric Pollution

Industrial Hygiene Section

Part I

Suggested Standards

THE committee's Suggested Standards were adopted as so-called "Working Standards" by the Section on Industrial Hygiene at the Milwaukee Meeting, 1935. They have been reprinted since that date in the Annual *Year Books* (with the exception of 1939-1940, when they were cited), and with only slight changes.

No changes have been made in the subjoined list of 15 items for Suggested Standards as published in the *Year Book* 1941-1942. However, considerable thought has been given to item 6 with the suggestion that it might read as follows, for which comments are invited:

"Surrounding surface temperatures (e.g., floor, wall, ceiling) a few degrees higher than air temperature during the heating season, and, except floor temperature, a few degrees lower than air temperature during the cooling season, wherever this can be obtained economically."

A two-season system composed of surface positive radiations during the heating season, and cooling ventilation only (that is, without purposeful radiation) during the cooling season, is a second suggestion. Third, simply a warmed floor during the winter and

cooled air during the summer might prove practical in many situations. Nothing should imply substitution of radiant methods for the present convection methods, except that a moderate amount of seasonal radiation is desirable wherever it can be obtained economically.

Outline of working standards for atmospheric and space environments for the maintenance of comfort, health, and efficiency, assuming altitudes not exceeding 10,000 ft. above sea level*:

1. Cool rather than hot †—but avoiding a sense of chilliness.
2. Dry rather than damp.†
3. Still ‡ or moving, depending upon physical activity.†
4. Some diversity in temperature—time and space—rather than uniformity and monotony.†
5. Foot level as warm as head level.
6. Radiant, i.e., local heat source as an item in heating, preferred.

* Agreements as to the majority of the exact specifications, of interest to engineers, and correlation with A.S.H.V.E. standards were summarized in the report of this Committee (*Year Book*, A.P.H.A., 1934-1935, pp. 108-112).

† Adapted from the British Health of Munition Workers' Committee, Memorandum No. 9, 1916.

‡ "Still" implies air motion under 25 ft. per minute.

7. Shockless temperature differentials between air conditioned quarters and outer air, depending upon the length of stay indoors, *i.e.*, less differential for brief stays.

8. Essentially noiseless conditioning apparatus.

9. Allotments for floor area, air space, and air supply should be sufficient to fulfil physical, physiologic, epidemiologic, and psychologic requirements of the occupants in any given enclosure.

10. Reduction of obnoxious dusts, bacteria, fumes, vapors, and gases to their sub-danger thresholds.

11. Satisfactory primary sense impression upon entering the room or space.

12. Maintenance of comfortable conditions during occupancy (room comfort impression).

13. Sufficient replacement of "foul air" with "fresh air" to meet odor-comfort requirements. Entrainment or filtering out of objectionable industrial odors.

14. Ultra-violet or actinic ray effects on air or occupied space to be deferred for later consideration.

15. Intelligent supervision.

The items of compressed and rarefied air are not considered here.

The Committee desires to call attention to *Report No. 76* of the Medical Research Council (Industrial Health Research Board), London, 1936, 109 pp., entitled, "The Warmth Factor in Comfort at Work. A Physiological Study of Heating and Ventilation, by T. Bedford. (Note especially "Equivalent Conditions of Warmth"—discussion of Scale with Chart—pp. 50-56 of this *Report*.)

EMERY R. HAYHURST, M.D.,
Chairman

PHILIP DRINKER

LEONARD GREENBURG, M.D.

WILLIAM J. MCCONNELL, M.D.

CAREY P. MCCORD, M.D.

The following paper by Professor Yaglou was presented at the St. Louis Meeting at the special request of the committee.

Defense Ventilation and Air Conditioning Problems

VENTILATION and air conditioning are contributing an important part in production for national defense. The necessity for uninterrupted production under conditions of blackout has led to the design of windowless "blackout plants" for airplane factories, munition plants, and for other key defense industries.

These plants are huge single-story buildings with few or no interior partitions. Raw materials go in at one end and finished products come out at the other. Except in cold weather, much artificial cooling is required to remove excessive heat from furnaces, machinery, and solar radiation. Aside from human comfort requirements, temperature control is essential to insure precision of finished parts for air-

planes, tanks, instruments, etc. Controlled humidity is often necessary to prevent rusting of highly finished parts; to maintain uniform regain in the manufacture of powder, and in the loading of fuses and shells; and to avoid generation of static sparks.

An undesirable feature in the design of some blackout plants is the lack of segregation of clean from the toxic process. Air pollution may be particularly aggravated in warm weather when the outside air supply is normally reduced to about one air change per hour in the interest of economy.

For small workshops and factories that are ventilated by natural methods, several types of blackout ventilators have been developed which obscure the outward passage of light without ob-

structing air flow too much. Some of these are equipped with a fan and are suitable for attachment to roofs or side walls.

Another interesting application of air conditioning is in blast furnaces of steel plants. It has long been known that removal of water vapor from the air supplied to blast furnaces increases their capacity, yields a more uniform product in silicon and sulfur content and reduces coke consumption. During periods of overproduction, manufacturers have shown little interest in this possibility, but with the present crisis in steel production there is considerable incentive.

The primary object of air conditioning is to dry the air blast and preheat it to about 1,300° F. The saving of fuel results from reducing heat wasted in dissociating water vapor. For every pound of water dissociated by intense heat, in the presence of reducing agents, 6,850 B.T.U. are absorbed and the waste is greatly reduced by drying the air.

Much more thought is now being given to the ventilation and air conditioning of ships than ever before. Air conditioning of gun turrets aboard fighting ships has speeded up the firing rate by removing powder fumes and keeping the temperature down. Submarines and sick bays of surface ships cruising in tropical waters are now cooled to overcome temperatures of 90 to 95° F. and humidities approaching the saturation point.

Despite official denials, rumors persist that some of the larger German tanks are cooled by refrigeration in the blistering heat of Libya. According to a French publication, refrigeration is accomplished by means of a methyl chloride absorption system utilizing exhaust gas heat for motive power.

Many other war uses could be added, such as the testing of aircraft engines, guns, and pilots in extreme cold, the

drying of foods to save shipping and storage space, the processing and storage of blood plasma, sera and vaccines, manufacture of synthetic rubber, etc.

In the field of industrial toxicology, war production has introduced new occupational hazards, requiring changes of medical procedures and of engineering methods of control. Some of the new chemical and physical irritants used are more toxic than the ones they have replaced.

An important improvement in hood design is the substitution of low resistance exhaust systems for the conventional high resistance systems, resulting in a substantial saving of power and of critical materials.

Among the new developments in air conditioning is the conduits system of ventilation which distributes conditioned air at high velocities through small conduits instead of large ducts. The system requires no more floor area and wall space than the steam pipes of a heating system.

The Public Buildings Administration has developed an inexpensive warm air furnace for low-cost defense houses which have no basements. The furnace has a capacity of 60,000 B.T.U. per hour, and utilizes an electric blower for circulating 600 c.f.m. of air. It is being used by practically all governmental agencies constructing defense houses.

A compact and inexpensive centrifugal air washer is being developed for decontaminating air from chemical war gases and mists by centrifuging and countercurrent washing with chemical solutions. It is intended for use in air raid shelters, trucks, tanks, and dug-outs, as well as in large public enclosures. Using suitable chemicals, it will dehumidify air to a low humidity at a fraction of the cost of present methods.

The War Production Board has re-

cently prohibited the manufacture, sale, and installation of new air conditioning equipment for all uses except where necessary to meet military and essential civilian needs. Another WPB ruling, applying particularly to defense housing, for which critical materials are to be allocated, limits the net hourly output capacity of the heating system to not more than 66 times the dwelling area in square feet or 80,000 B.T.U. per dwelling unit, whichever is the smaller. Government regulation of the maximum heat transfer coefficient of building materials is a step in the right direction even in peacetimes, and has long been in force in Germany and in the Netherlands. In Sweden the use of double windows is compulsory.

Fuel conservation has now become a wartime "must," at least on the Eastern Seaboard. Some medical men believe that compulsory reduction of house temperature to 65° F. may prove beneficial to health, but the majority of workers on the subject expect considerable discomfort and perhaps a few more "colds" until persons adapt themselves to this lower standard. There is no

good evidence to show that a temperature of 65° in the house, office, or school menaces health, but there is much proof that it affects seriously the American standard of comfort.

Discomfort will be greatly alleviated by insulating buildings to keep exposed walls and windows warm, by wearing heavier underclothing, and by stopping drafts from fire places and doors. Fundamentally, the problem of fuel saving is not so much a matter of drastic reduction of indoor temperature as one of insulation and thrift in the use of fuel. In average New England winters, a reduction of indoor temperature from the customary 72° to 65° F. will reduce fuel consumption by not more than 20 per cent, or almost as much as can be saved by weather stripping of windows and exposed doors. Complete house insulation, including wall and roof insulation in addition to weather stripping, may save as much as 60 per cent of fuel, and, by shutting off unused rooms, still greater economy may be expected. FHA loans are available for house insulation and can be paid back out of fuel savings.

C. P. YAGLOU

Part II

Standard Methods for the Examination of Air

THIS committee, organized at the Pasadena Meeting in 1934, and representing the Industrial Hygiene, Engineering, and Laboratory Sections, has reported annually in the *Year Book*, chiefly through its four subcommittees, one of which, that on Chemical Methods, reports this year on the determination of cadmium in air.

As heretofore, comments and suggestions are invited and may be taken up with any member of the committee or

subcommittees, as befits the subject matter.

CAREY P. McCORD, M.D.

I. Report of Subcommittee on Physical Procedures in Air Analysis

THIS committee directs attention to its report in the *Year Book 1938-1939*, entitled "Instruments and Methods for Recording Thermal Factors Affecting Human Comfort," in which very slight changes were recommended as published in the *Year Book 1939-1940* (page 91).

The committee is digesting the latest advances in the field which it plans to incorporate in a revised report next year.

C. P. YAGLOU, *Chairman*
ALONZO P. KRATZ
C-E. A. WINSLOW, DR.P.H.

II. Report of Subcommittee on Chemical Methods in Air Analysis Cadmium and Hydrogen Sulfide

THIS year's report includes the determination of cadmium and hydrogen sulfide, two contaminants which are of immediate interest in the war effort.

DETERMINATION OF CADMIUM IN AIR *Occurrence and Method of Collection:*

Cadmium as an air contaminant occurs usually as the oxide in the form of a dust or fume and may be collected in the impinger with water as the medium, or with the electrostatic precipitator.

Cadmium (Cd) has an atomic weight of 112.41, melting point 321° C., boiling point 767° C. Cadmium volatilizes when heated and burns, yielding a fume of brown cadmium oxide (CdO).

The American Standards Association has set the maximum allowable concentration of cadmium or of its compounds at one milligram of cadmium per 10 cubic meters of air (Nov. 2, 1941). The literature cited included the following methods.

Cadmium Sulfide Method

Procedure:

Transfer the sample to a 250 ml.

Phillips beaker and add sufficient nitric acid for the destruction of any organic material which may be present. Add 10 ml. sulfuric acid (1:1) and heat until fumes of sulfur trioxide are freely given off. Dilute to 75 ml. and add 1 ml. of copper sulfate solution (200 mg. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in 100 ml. H_2O). Add 2 gm. of sodium citrate. Neutralize the solution with ammonia and adjust the acidity to $\text{pH} = 3$. Pass hydrogen sulfide into the resulting solution for about 10 minutes, add 1 drop of 5 per cent aluminum chloride solution and allow to stand 6 to 12 hours. Filter, dissolve the precipitate in nitric acid and hydrochloric acid and carefully evaporate to dryness. Take up the residue in water, and make up to a convenient volume in a volumetric flask. An aliquot portion of this solution is used in a Nessler tube for the final reading.

Add 5 drops of 10 per cent potassium cyanide to the aliquot in the Nessler tube, 5 ml. of hydrogen sulfide water, and make up to the mark with distilled water. Mix thoroughly and compare under flood of ultra-violet light with

standards similarly prepared. The solution should exhibit a bright clear yellow color under the mercury arc.

A standard cadmium stock solution may be prepared from cadmium metal by dissolving 1 gm. of cadmium in nitric acid and making the solution up to 1 liter in a volumetric flask. Any other suitable cadmium salt, such as the sulfate, may be substituted if cadmium metal is not available.

The sample tubes and the standard tubes should be prepared at the same time as there is a notable deepening of tone when they are allowed to stand overnight. In doubtful cases, however, it is sometimes advantageous to allow the tubes to stand for a few hours before reading. Concentrations of cadmium as low as 0.02 mg./50 ml. may easily be distinguished by this method.

β -Naphthoquinoline Method

This method has been described for quantities of cadmium down to 1 mg.

Procedure:

Dissolve the cadmium by treating the sample with 50 ml. 2 normal sulfuric acid and 50 ml. 10 per cent sodium tartrate solution. Add an excess of a 2.5 per cent solution of β -naphthoquinoline. (Made by dissolving β -naphthoquinoline in N/2 H_2SO_4 .) Precipitate the cadmium by adding a suitable amount of N/5 potassium iodide solution. Total volume about 150 ml.

The precipitate is filtered after 20 minutes, preferably by suction and sucked as dry as possible. It is washed with a solution obtained by adding 10 ml. of N/5 potassium iodide to 10 ml. of sulfuric acid-naphthoquinoline solution diluted with 90 ml. of water. It is best to add an additional 2 or 3 ml. of potassium iodide solution to the first two portions of wash solution in order to be sure of removing any excess acid in the precipitate.

The filter is now washed down with 20 ml. of 2 normal sodium hydroxide or ammonia, acidified with sulfuric acid, making the acid concentration about 5 per cent, and then titrating with N/10 potassium iodate solution. This may be done according to the method of Berg by adding practically an equal volume of acetone and using starch as the indicator.

Calculation:

1 ml. N/10 potassium iodate = 0.9366 mg. cadmium.

HYDROGEN SULFIDE

Hydrogen sulfide is encountered rather infrequently as an industrial chemical compared to its occurrence as a by-product of some industrial or natural process. It is a very toxic gas and the maximum allowable concentration for exposures not exceeding a total of 8 hours daily has been set at 20 p.p.m. parts of air by volume, by the American Standards Association in January, 1941.

Methods applicable to the detection and estimation of hydrogen sulfide include lead acetate test papers as used by the British Department of Scientific and Industrial Research, the silver cyanide detector developed by the U. S. Bureau of Mines, and the cadmium sulfide method. Other reagents for hydrogen sulfide include iodine, sodium nitroprusside, and p-aminodimethylaniline sulfate. The cadmium sulfide method is practical, accurate, and quite specific. It is recommended as the reference method.

Collection of Sample:

Two simple bubblers such as the petticoat type, in series, containing 10 per cent cadmium chloride solution are

used to collect hydrogen sulfide gas. Ammoniacal cadmium chloride solution or a slightly alkaline cadmium chloride solution may also be used with advantage. A single fritted glass bubbler operating at a rate of 0.5 to 1 liter per minute is also satisfactory, provided that a separate bubbler is used for each sample.

Procedure:

Transfer the contents of the bubbler with rinsings to a 250 ml. Erlenmeyer flask. Add a few ml. of sulfuric acid and titrate with standard iodine solution, using starch as an indicator. The solution may also be back-titrated with sodium thiosulfate after the addition of excess iodine solution. Add 5 ml. of .05 N iodine followed immediately by 2 ml. of acid. After 10 minutes back

titrate with .05 N sodium thiosulfate.

Calculation:

1 ml. N/100 iodine = 0.112 ml. of H_2S at $0^\circ C$. 760 mm. Hg.

An alternate method consists in comparing the amount of cadmium sulfide with standards of known sulfide concentration according to the method for cadmium as outlined above.

Duties of Nurses in Industry

Public Health Nursing Section

THE industrial expansion occurring throughout the United States and the increasing understanding of the importance of the health of workers made necessary some consideration of the factors influencing the development of an industrial nursing program. For this reason the Public Health Nursing Section of the American Public Health Association at its 1940 Annual Meeting authorized the appointment of a special committee to be known as the Committee to Study the Duties of Nurses in Industry. This committee became active early in 1941 and planned a nation-wide industrial nursing survey. Such a survey was to serve as the basis (1) for determining the range of nursing activities included in all types of industrial nursing services, (2) for formulating a statement of recommended practices in industrial nursing, and (3) for defining the current problems confronting nurses in industry.

THE PRELIMINARY SURVEY

The committee decided before undertaking a survey on a nation-wide scale to do a preliminary survey. For this purpose a form and accompanying instructions defining the items on the form were prepared. During the summer of 1941 the form was used by committee members in 109 establishments which employed 235 nurses. Whenever possible the general plans for the survey and the practicality of procedures to be followed were discussed with the

industrial nurse being interviewed and with the organized group of industrial nurses in the area, if such a group existed.

The results of the preliminary survey were presented in a progress report to the Public Health Nursing Section at the 1941 Annual Meeting of the American Public Health Association. At this time the Section accepted the several recommendations of the committee. The first recommendation was to continue the survey on a nation-wide scale since the report indicated that such a survey would be of sufficient value to warrant the effort, and the procedures as established seemed to be practical.

The second recommendation provided for the establishment of two committee groups, the Advisory Group, and the Working Group. A third group, the Consultant Group, was decided upon at a later meeting of the committee. The third recommendation authorized the committee to request the Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service, to guide and direct the survey and to assume the responsibility for the tabulation and analysis of the collected data.

ORGANIZATION OF COMMITTEE GROUPS

The *Advisory Group* was made up of representatives of organized groups of industrial nurses throughout the country. In some areas where the industrial nurses were not organized a

well known industrial nurse was invited by the committee to serve on the Advisory Group.

The functions of the Advisory Group were (1) to assist with the planning for and the conduct of the survey, and (2) to prepare recommendations of acceptable practices of industrial nursing based on the survey findings.

The appointment of the Advisory Group stimulated organizations of local industrial nurses' associations and afforded industrial nurses an excellent opportunity to plan for the development of practices in their own field.

The *Working Group* was composed of nurses on staffs of state health departments. The chief function of this group was the collection of data for the survey. In those states where a nursing consultant for industrial hygiene was employed, she was made responsible for collecting the data. In other states, arrangements were made for the staff of the division of public health nursing to accept this responsibility.

Serving on the Working Group afforded the consultants of the several divisions of industrial hygiene of the respective state departments of health an opportunity to become acquainted with the industrial nurses and the problems relating to industrial nursing in their respective districts. Likewise the nurses on the staff of the divisions of public health nursing who participated in the collection of the data acquired more knowledge of and greater interest in industrial nursing.

The *Consultant Group* was made up of representatives of the Council on Industrial Health of the American Medical Association, the American Association of Industrial Physicians and Surgeons, the American Industrial Hygiene Association, and the National Conference of Governmental Industrial Hygienists. Its function was to advise on all matters pertaining to the survey.

COMMITTEE ACTIVITIES

In general, committee and group activities were carried on through correspondence. However, several meetings were held, the first of which was held in November, 1941, and included members of the Advisory and Working Groups. At this time the form used in the preliminary survey was revised and plans were completed for conducting the survey on a nation-wide scale. Two other meetings were held in April and May, 1942, for the purpose of reviewing the progress made during the first two months of work and discussing problems encountered in collection of the data.

The final meeting of the Advisory Group was held in January, 1943, after the official termination of the activities of the committee as a whole. The group then prepared recommendations on acceptable practices of industrial nursing.

A report of the analysis of the findings of the survey data collected up to October, 1942, was given in a paper read before the Joint Session of the Industrial Hygiene and Food and Nutrition Sections at the 71st Annual Meeting of the American Public Health Association, St. Louis, Mo., October 29, 1942.

By official action of the Public Health Nursing Section, the committee was formally dissolved with the understanding that further study of the data was to be carried on at the National Institute of Health and the final report containing the recommendations to be prepared by the Advisory Group would be published by the Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service.

RESULTS OF THE SURVEY AND RECOMMENDATIONS OF THE ADVISORY GROUP

NATURE AND SCOPE OF THE SURVEY

The committee was successful in ob-

taining completed schedules on 924 industrial establishments employing approximately 2,500,000 workers and located in 36 states and the District of Columbia. The information was collected through personal interviews with the plant nurse or other plant official by consultant nurses in the divisions of industrial hygiene, by staff nurses in several state departments of public health nursing, and by committee members. The survey was begun in March, 1942, and continued through December of the same year.

Eighty-four per cent of the plants were engaged in manufacturing and included a large number of essential war industries producing aircraft, ships, machinery, ordnance material, and clothing for the armed forces. Federal as well as private industries producing ordnance material were surveyed. The remaining 16 per cent of the plants were non-manufacturing industries and included coal mines, metal mines, construction projects, department stores, public utilities, insurance companies, banks, and several service industries.

The plants varied widely in size. Over one-half (58 per cent) of the industries with full-time nursing services employed from 500 to 2,500 workers. Sixteen per cent had less than 500 workers and 26 per cent employed more than 2,500 workers.

In general, the aim of the committee was to obtain as much data as possible on industrial establishments maintaining what is known as "nursing service." For this reason three distinct types of nursing service were sampled; namely, in plants in which the nursing activities were carried on by at least one full-time registered graduate nurse; in plants employing a registered graduate nurse on a part-time basis; and in plants in which such activities were carried on solely by non-professional personnel such as practical nurses or first aid attendants. Some of the non-

professional personnel had completed Red Cross or Bureau of Mines first aid courses.

The first group of plants, those employing at least one full-time registered graduate nurse, predominated and constituted the chief group for purposes of the survey. Of the 924 plants surveyed, 868 were of this type and employed a total of 3,027 nurses. The National Survey of Registered Nurses showed that in 1941 there were some 6,000 industrial nurses in the country on both active and inactive status. Recent estimates indicate that in 1942 this number probably had increased to 9,000 or 10,000. If this figure is correct, the activities of approximately one-third of the registered industrial nurses in the country are covered by the survey.

The other two groups of plants were comparatively small. Twenty-two plants with part-time nursing service were surveyed. In 34 other plants, nursing service was rendered by practical nurses or first aid attendants.

FACTORS INFLUENCING RANGE OF DUTIES

The survey revealed that the duties of industrial nursing personnel ranged from "strictly first aid" to an all inclusive program embracing the present concept of health promotion in industry. Such activities include care and treatment of injured and ill workers, assistance with medical examinations, participation in health education programs, assistance with safety education and accident prevention, assistance with plant sanitation, participation in welfare activities, and home nursing services.

The nurse may be engaged in one or all activities pertinent to such programs. The extent to which she participates is determined not only by the attitude of the management toward health and welfare of employees, the differing occupational needs and health

requirements of workers, but also her own professional preparation, vision, and initiative.

When the type of medical service provided in the plant was considered, the analysis indicated that the responsibility delegated to the nurse was greater and her activities were more numerous in industries where the physician was on call than in those plants where the physician served part-time or full-time, particularly in the latter case. Physicians served full-time in 23 per cent of the plants surveyed, part-time in 37 per cent, and on call in 40 per cent.

When nurses' activities were correlated with plant size as determined by the number of workers, similar trends were observed but not to the same degree as in the cases of classification by type of medical organization.

Three other factors influencing the duties and responsibilities of the industrial nurse are (1) the provision for written standing orders or written procedures, (2) the type and extent of nursing supervision, and (3) the relation of the medical department to other departments in the plant organization.

WRITTEN STANDING ORDERS

It is a recognized principle that all nursing care should be given under the direction of a licensed physician. It will be noted that 77 per cent of the industrial nurses surveyed were employed in plants where the physician served part-time or on call, and hence it was necessary for the nurse to assume greater responsibilities. Suitable instructions in the form of written standing orders should be provided by the part-time or on call physician to insure satisfactory service during his absence. It is the responsibility of the nurse to secure such orders. Standing orders are a protection to the nurse, to the worker, and to the management.

Written orders outlining the procedures to be followed were provided for nurses in 42 per cent of the plants with full-time physicians, in 37 per cent of the plants having part-time physicians, and in 30 per cent of the plants where the physician is on call. Thirty-six per cent of all plants surveyed provided written standing orders for nurses.

Recognizing the serious import of these findings, the Advisory Group made the following recommendations. *Nurses working without the direction of a full-time physician should have written standing orders. Where no one physician is responsible for the plant medical service, the nurse may secure standing orders from the committee on industrial health of the county medical society.* Further, the nurse working under the direction of a full-time physician should have written procedures for her guidance. In plants where non-professional workers are employed, written standing orders and/or written procedures should be furnished for the guidance of such personnel.*

SUPERVISION

While it was not possible to determine from the data the effect nursing supervision had on the extent or character of the nurse's participation in the plant services, undoubtedly this is a contributing factor. Provision for nursing supervision was reported in 48 per cent of the 420 plants employing two or more nurses. After consideration of this factor, the Advisory Group defined supervision as follows:

Supervision is a democratic situation in which a person who has had opportunity to acquire a broad knowledge of her field and

* Suggested written standing orders have been prepared by the Council on Industrial Health of the American Medical Association and have been made available to the component societies for the use of their state and local committees. Several state divisions of industrial hygiene have prepared suggested standing orders which are available to industrial nurses.

has proved her ability offers to share her knowledge and experience with another person in such a way as to help that person to do better work more easily and with greater satisfaction.

Believing in the importance of nursing supervision for industrial nurses, the Advisory Group recommended that *where two or more nurses are employed, one nurse be designated as one of the following, depending upon the size of the nursing staff and the amount of responsibility delegated to her: director of nursing service, nursing supervisor, chief nurse, head nurse, or charge nurse. Further, when the nursing staff of the particular industry is not sufficiently large to warrant the employment of a nursing supervisor, the facilities for advisory service offered by the state department of health or the insurance company should be utilized.*

As has been previously pointed out, the character and extent of nursing participation in the industrial health program is dependent upon the nurse's professional knowledge and understanding. One of the ways in which her professional growth and development can be fostered is through membership in professional organizations. Nurses should maintain their professional affiliations and be interested in keeping up with advances in their profession. The affiliations desirable are alumnae, district and state associations and the American Nurses Association, the local industrial nurses groups and the American Association of Industrial Nurses, the state organization for public health nursing, and the National Organization for Public Health Nursing.

RELATION OF MEDICAL DEPARTMENT

The relation of the medical (including nursing) service to other departments within the plant organization has considerable influence on the development of health service. To facilitate the effective operation of the

medical department the person in charge should be able to discuss problems with top management. Management should consider its medical department as an asset rather than a luxury, or, as in some instances, a liability. It should be given the status which it merits on a par with operations. It was recommended that *the medical department, regardless of size, should be responsible to an executive of the organization.*

ACTIVITIES

The following summary is based on the analysis of the activities of 3,027 full-time registered graduate nurses employed in 868 establishments, irrespective of plant size or the prevailing type of medical organization. The recommendations concerning each activity were prepared by the Advisory Group.

Nursing care and treatment—Nursing care and treatment of occupational injuries and illnesses and emergency care of non-occupational illnesses was carried on by practically all of the nurses included in the survey. However, there were a few industrial nurses employed for mining and textile mill villages who gave no nursing care and treatment in the plant, but served the workers and their families in the latter's homes.

Hospital nursing may also be a function of the industrial nurse. Thirty-seven establishments operate their own hospitals. In all but two of these, nurses rendered nursing care to hospitalized workers and, at times, assisted in the plant dispensary.

In plants where a full-time physician is employed, the nurse's responsibility for care and treatment is limited to assisting the physician, or to the care of workers who do not need the attention of the physician. In plants employing a physician part time or on call, the nurse sees all workers who are injured

or ill and exercises judgment relative to medical treatment. She may administer the necessary care, give emergency care until the part-time physician makes his regular visit, or refer the worker immediately to a physician or to the hospital.

The importance of the nursing care and treatment phase of industrial nursing is frequently minimized by other professional groups. However, it requires professional competence, skill, and the exercise of judgment, particularly in plants where only part-time or on call medical service is provided.

Assistance with medical examinations—The second major activity of industrial nurses is assistance with medical examinations of workers. Over three-fourths, or 82 per cent, of the establishments did medical examinations of the workers either as a part of the preplacement or of the employment policy. This large proportion is accounted for by the fact that only those plants with some type of medical program were surveyed.

Practices differed as to where the medical examinations were performed. It was found that nurses assisted in 78 per cent of the 464 establishments which provided for medical examinations of workers at the plant, and in 10 per cent of the 250 plants which arranged for examinations at the physician's office, the hospital, or at some central clinic.

Although it would seem that a high percentage of the nurses assist with medical examinations, the data indicated that such assistance was frequently limited in extent. In some plants, nurses assisted with many of the following activities: taking the history, recording the findings of the physician, chaperoning female workers, testing vision and hearing acuity, measuring height and weight, taking readings of blood pressure, temperature, pulse and respiration, and taking speci-

mens for serological and other laboratory tests. In other plants nurses performed only one or two of these activities. Apparently more adequate health services in industry could be provided by further utilization of nursing skills.

The nurse's assistance during the medical examination may aid the physician to secure the worker's understanding (1) of the value and use of the medical service, and (2) of the value of the examination and the procedure to be followed. In addition, her assistance will conserve the time of the physician.

It was recommended that *nursing assistance in the medical examination, both preplacement and other types, should include the following activities: (1) Interviewing the worker previous to the examination; (2) doing routine tests and explaining their significance; (3) taking specimens for serological and other laboratory examinations and explaining their significance; (4) interpreting to the worker plant policies regarding health and welfare and his responsibility for coöperation; (5) making periodic inspections for symptoms and indications of occupational diseases; and (6) making inspections and interviewing workers in connection with return-to-work permits.*

Nurses were called upon to do the urinalysis in one-half of the 370 establishments where physical examinations which required laboratory tests were made in the plant. The examination was usually limited to testing for sugar, albumin, and specific gravity. In 9 plants nurses performed the complete function of a laboratory technician and did serological and other indicated tests.

Although a large proportion of the establishments arranged for x-rays of workers when such were indicated, the survey showed that only 170 were equipped with x-ray equipment. In almost one-half (48 per cent) of these

plants the work was done by the plant nurse.

These data show that a fairly large number of nurses were engaged in special technical services not usually included in professional nursing preparation and for which trained technicians could have been secured. It was necessary for the nurse in these cases to learn the several technics before she could successfully perform the duties involved. The volume of work required, the physician's preference, and the attitude of the management toward the employment of technicians are some of the factors which determine the nurse's participation in these activities.

Since it is frequently necessary for the industrial nurse to do laboratory work, take x-rays, give physiotherapy treatments, make electro-cardiograms and basal metabolic tests, the Advisory Group recommended that *the nurse have special training in the technics of rendering each of these services when they are required of her. However, when the volume of special technical services requires the time of one individual, a technician rather than a nurse should be employed.*

Participation in health education program—Modern concepts of industrial health have perhaps wrought more changes in the field of health education than in any other aspect of the industrial health program. The survey indicated that nurses did very little health education work. However, the incompleteness of records and reports concerning such services rendered by the nurses prevented collection of reliable data on this activity.

Informal counselling with workers during the course of treatment, the distribution of health literature, and the follow-up of remediable physical defects were some of the specific ways in which nurses were participating in health education.

Organized health education programs

were carried on in less than 20 per cent of the plants. These embrace preventive as well as promotional activities in the control of tuberculosis, syphilis, colds, and occupational diseases, and in the field of dental hygiene, mental hygiene, fatigue, and rehabilitation of the worker.

It is generally conceded that an industrial nurse has almost unlimited opportunity for health education and health supervision of industrial workers. The extent to which she takes advantage of this opportunity depends on her ability and understanding as well as on plant policies. Also in industries where a high occupational injury rate exists the volume of treatments may prevent the nurse from utilizing the opportunities for health education. Further, since the medical examination records are not available to the nurse in many plants, this obviously limits the amount and quality of health instruction she can give workers. Finally, a planned program for health education and supervision of workers comparable to the safety education and accident prevention program in force in many plants is essential if the nurse's participation is to be effective.

Conservation of the health of industrial workers in order to improve efficiency and lessen absenteeism is recognized as vital to production. Therefore, the Advisory Group recommended that *the nurse's participation in the plant health education program be extended and improved. Such a program should include definite plans for: (1) Follow-up for correction of remediable conditions; (2) supervision and rehabilitation of workers with adverse health conditions; (3) maintenance of complete records showing care given for non-occupational conditions; (4) health teaching in the training program; (5) utilization of community resources including private physicians, health and welfare agencies.*

Another health education activity is the teaching of formal classes. One hundred and ten nurses indicated that they taught regularly scheduled classes in home nursing, standard or advanced first aid. Frequently, not only workers but also their families enrolled in these classes.

Home nursing classes afford the woman worker an opportunity to improve her knowledge of general health and to gain an understanding of methods of caring for sick members of her family. First aid instruction makes the worker more safety conscious. It was recommended that *nurses in industry take the necessary steps to become authorized Red Cross Home Nursing and First Aid Instructors.*

Assistance with safety education and accident prevention—Although at times the nurse's conception of the extent of her activities in health education and promotion among workers was vague, usually little doubt existed concerning her part in the safety activities of the plant. In some cases she had complete responsibility for such activities; in other cases her duties were limited to the preparation of reports on accidents and to attendance at meetings. In 34 per cent of the 674 establishments which have organized safety committees, nurses participated as members. In fact, two of the nurses were safety committee chairmen, and 24 were secretaries. In another 5 per cent, nurses reported that, although not members, they attended meetings and often gave talks on safety education.

Nurses assisted actively in plant accident investigations in 41 per cent of the plants. They went to the scene of the accident, interviewed witnesses, and conferred with the foreman concerning recommendations for prevention of similar accidents. Fifty nurses reported voluntarily that they were responsible for the purchase, distribution, and maintenance of goggles, safety

shoes, respirators, uniforms, and similar protective equipment.

The amount and character of the nurse's assistance with the safety education and accident prevention program is due in a large measure to the fact that provision is made through plant policy for such a program and that state laws and insurance company practices require adequate and complete records of compensable occupational disabilities.

It is recognized that many of the services now being rendered by nurses are not essentially nursing. However, the contribution which industrial nurses can make to the reduction in the rate and severity of accidents should not be minimized. Therefore, the Advisory Group recommended that *the nurse should not be responsible for the planning or direction of the safety program but that she assist in the following activities: (1) Proper placement of workers according to physical and mental fitness; (2) teaching the training course; (3) safety committee work; (4) record and report keeping; (5) individual instruction of workers regarding accident prevention; (6) visual education, movies, posters, and printed material; and (7) distribution and care of protective equipment.*

Assistance with plant sanitation—In industries where sanitary engineers are employed, the responsibility of the nurse is limited to the assistance of sanitary inspections of toilet, wash, rest, and change room facilities for women workers. Nurses in 9 per cent of the establishments surveyed performed this duty. In another 23 per cent, they also assisted with inspections of ventilation, lighting, and housekeeping facilities. Nurses assumed the complete responsibility for routine plant inspections in 5 per cent of the establishments. Many nurses reported voluntarily that they were responsible for the supervision of matrons when such

were employed, and likewise for the cleaning force.

It was recommended that *the nurse show an active interest in all phases of plant environment that affect the health and morale of the worker. However, direct responsibility for the supervision of plant sanitation should be delegated to other departments whenever possible.*

Participation in welfare activities—In general, the workers avail themselves of the opportunity to discuss their financial, marital, religious, and other home troubles with the plant nurse. Many plants provide a special department to handle the worker welfare activities. In such plants the nurse refers the problems to that department for further action. Otherwise, she may assume complete responsibility for welfare activities.

In addition, nurses indicated that they were responsible for the inspections of the cafeterias in 43 plants, and gave dietary advice to cafeteria managers in 13. The nurses managed the cafeteria or lunchroom in 8 plants, including the hiring and firing of workers, planning menus, and ordering of supplies.

Welfare activities in a plant are recognized as contributing to the morale and efficiency of the worker. Therefore, it was recommended by the Advisory Group that *nurses participate in and promote welfare activities. The nurse's participation may include: (1) Development of group sick benefits, hospitalization, and life insurance plans; (2) personal counselling with workers regarding welfare problems; (3) development of recreation program; (4) coöperation with local welfare agencies; (5) planning of cafeteria, lunch rooms and canteen services.*

Home nursing service—In 21 per cent of the establishments surveyed, nurses made at least 5 home visits a month, in addition to performing their duties in the dispensary. Additional nurses

were employed for home visiting in 6 per cent of the plants. Among the reasons for making home visits are: (1) To give health supervision; (2) to determine eligibility for benefits; (3) to ascertain causes of absence; (4) to assist the worker with his social problems; and (5), less frequently, to give nursing care to the ill or injured worker. A few other establishments have arrangements with the local nursing associations or contracts with insurance companies for home visits. Three of the reasons for which visits are made to the homes of workers, namely, those to determine eligibility for benefits, to ascertain cause of absence, and to assist the worker with social problems, do not require the skills characteristic of nursing but may be essential to the service.

Home nursing care for injured and ill workers aids in the promotion of the general health, reduces absenteeism, and contributes to the morale of workers. The data indicated that this service is seldom rendered by plant nurses. However, when home visits are made by the staff of a nursing association, either through provisions of group insurance or arrangements between the plant and the association, the primary purpose for making the visit is to give nursing care.

Several factors make it more desirable for an industry to enter into a contract with a local visiting nurse association rather than to employ a nurse for home service. The travel time necessary for a nurse to make a special trip to the home of a worker who is commuting from a great distance makes the cost of such visits in time and money impracticable. In this connection the recognition on the part of industrialists of the need to avoid duplication of service—duplication of activities performed by a community agency in which they as responsible citizens of the community are interested—is of great importance. When this factor is

fully appreciated, industry will recognize the advantage of having the community nurse serve the plant for all home visiting, inasmuch as she may already be serving the family, and therefore is in a position to contribute her knowledge of family health problems to the industrial medical department.

After review of the data the Advisory Group recommended that *home nursing service be provided by the plant. The plan for visiting sick or injured workers in their homes should be developed to secure maximum benefits to the workers and to the plant. Employment of nurses for this service may be necessary where community resources are not available or cannot be coordinated with company policy.*

Records and reports—Another important function of the nurse is completing and filing records and preparing reports of first aid activities. All nurses keep records of treatments. Some are complete and others quite sketchy, depending on the requirements of the management and the nurse's own knowledge of such matters. The analysis revealed that nurses were given clerical assistance with their records and reports in 35 per cent of the establishments. Medical departments in the larger plants are usually staffed with full-time clerks and stenographers, relieving the nurse completely of this responsibility.

In 65 per cent of the establishments nurses were required to submit periodic reports on activities of the plant dispensary to the management or to the physician in charge. In 56 per cent of the plants nurses assisted with workmen's compensation reports.

Records and reports are to the industrial nurse what bookkeeping is to the accountant. They make it possible for her to prove to management the desirability of and the value derived from industrial nursing service.

It was recommended that: (1) *The medical records be kept strictly confidential except as interpretations of them are needed by management;* (2) *all medical records be kept in the medical department and available for use each time a worker presents himself for care;* (3) *when the physical examinations of workers are made outside the plant, the records or copies thereof be made available to the nurse;* (4) *clerical assistance be provided in order that the nurse's time may be conserved and records adequate.* Further, the following types of records and reports are needed: (1) *Daily record or log;* (2) *individual record including the medical examination, clinical visits, and the correction of remediable conditions;* (3) *disability absentee records;* (4) *compensation records and reports;* and (5) *monthly and annual reports to management.*

CURRENT PROBLEMS OF INDUSTRIAL NURSING

One of the objectives which the committee hoped to achieve through the survey was some insight into current problems of industrial nursing. However, when the original plans for the survey were made, the committee did not anticipate the war and the accompanying demands for nursing service which we are witnessing today.

The extent to which nursing services in industry have expanded is revealed strikingly by the survey. Of the 2,450 full-time registered nurses for which data were available, 40 per cent began their employment in 1942. Between January, 1940, and December, 1942, more than two-thirds, or 70 per cent, of the nurses began their employment. Thirty per cent were on their present jobs prior to 1940.

Thirteen per cent of the 850 plants for which data were available established nursing services for the first time in 1942. Thirty per cent of the serv-

ices were established during the last three years. It is interesting to note that only 7 per cent of the remaining plants established nursing services prior to 1915.

As a result of the unprecedented demand for graduate registered nurses in industry, numerous questions have arisen: What professional channels, if any, are utilized in the selection of these nurses? What qualifications are required? On what basis is salary determined? Are they employed to render services essential to the maintenance of the industrial health program? Is the nurse's time conserved wherever possible? What is the desirable number of nurses per unit of employees? Could a part-time nursing service meet the needs of the plant?

SOURCE OF SUPPLY

In the past many employers have not been aware of the professional channels through which nurses might be secured for positions in industry. Various sources have been used with the result that frequently the selection of the nurse has been made without giving proper consideration to duties and responsibilities of the position.

The Advisory Group recommended that *nurses for industry be obtained through professional nursing channels such as: (1) registries approved by local or state nurses' associations; (2) Nurse Placement Service*;* (3) *schools of nursing and universities offering courses in industrial hygiene; (4) insurance companies; and (5) divisions of industrial hygiene in state departments of health.* It was further recommended that *the local industrial nurses group act in an advisory capacity to the above organizations in regard to the needs of industry and nurses who are available.*

QUALIFICATIONS

In order to assist management and others interested in the employment of industrial nurses, desirable qualifications were enumerated by the Advisory Group as follows:

A. Personal

1. An interest in, and an ability to work effectively with, all types of people
2. Good physical health
3. Emotional stability
4. Initiative and good judgment
5. Resourcefulness
6. Ability to organize, especially where nursing supervision is not provided
7. Ability to appreciate the importance of one worker's health to the efficient operation of the industry as a whole

B. Academic

1. High school graduation
2. Advanced education on a college level—desirable
3. Ability to type for the purpose of record keeping—desirable

C. Professional

1. Graduation from an accredited school of nursing connected with a hospital which had a daily average of 100 patients or affiliations with other schools of nursing which provide a broad clinical experience in medical, surgical, obstetrical and pediatric nursing
2. Registration in the state of employment in accordance with the Nurse Practice Act
3. Postgraduate study in industrial nursing with public health aspects—desirable

D. Experience

Experience in hospital emergency room, out-patient surgical department, industrial clinic, and public health nursing—desirable.

It was recommended that *industrial nursing organizations make an effort to encourage the employment of nurses who have had the industrial nursing preparation which is available at the present time.*

SALARY

It seems logical to expect that the basis for salary (or compensation) should be the same as that for supervisors of departments, according to the

* S South Michigan Avenue, Chicago, Ill.

responsibilities involved and the qualifications and experience which are required. The Advisory Group recommended that *a job analysis be made to depict the responsibilities involved in the particular position and that the salary be commensurate with these responsibilities.*

ESSENTIAL SERVICES IN INDUSTRY

The National Nursing Council for War Service recommends¹ that industrial nurses who are not essential for maintaining minimum health services should serve with the armed forces.

It is considered that the industrial nurses who are essential for maintaining minimum health services are:

1. The nurses who have established health programs in essential industries
2. The nurses who are holding administrative or supervisory positions in the medical departments of essential industries
3. The nurses who have special skills or preparation essential to the maintenance of medical departments

In accordance with this policy the Advisory Group recommended that *staff nurses who are eligible for military service and who may be replaced by nurses not eligible for such duty should be encouraged to enroll for service with the armed forces and should be granted military leave.*

NON-PROFESSIONAL CLINIC ASSISTANTS

In keeping with the national effort to conserve nurse-power during the war emergency, it was recommended that *non-professional clinic assistants be employed in so far as possible, and that the following duties be assigned to them: (1) Securing of specimens and care of specimen bottles; (2) filling of hot water bottles and ice bags; (3) bed making; (4) sterilization of instruments and supplies; (5) assistance with*

dressings; (6) making surgical supplies; (7) care of change rooms, rest rooms, and toilets; (8) training of matrons. It was further recommended that *there be written instructions governing the activities of the non-professional clinic assistants and that such assistants be supervised by the nurse.*

DUTIES OUTSIDE THE MEDICAL DEPARTMENT

The analysis revealed that the activities of nurses are not necessarily confined to the medical department. They range from selling telephone slugs and defense bonds to delivering babies. Nurses act as receptionists, relieve in the canteen or at the switchboard. They attend funerals and weddings, and write letters of congratulations and condolences. Nurses in 91 plants reported that they assist with the clerical and secretarial work in other departments of the plant, figure out wage rates and make out and distribute pay checks. In 30 plants they engage actively in personnel work, hire and fire employees, and keep worker employment records. In 25 plants nurses fingerprint and photograph employees and give identification badges.

In many instances when a nursing service is being initiated by industry the nurse combines with her nursing functions various duties unrelated to health services. Since it has been demonstrated that a plant employing as few as 100 workers can profitably employ a nurse full time, it was recommended that *the nurse's activities be limited to those of the medical department.*

NUMBER OF NURSES PER UNIT OF EMPLOYEES

The number of nurses employed should depend on the type of industry and the number of workers. For the maintenance of complete health service

¹ *Priorities for Nurses.* National Nursing Council for War Service, 1790 Broadway, New York, N. Y.

in an industry it was recommended that *there be 1 nurse for up to 300 employees, 2 or more nurses for up to 600 employees, and 3 or more nurses up to 1,000 employees, 1 nurse for each additional 1,000 employees up to 5,000, and 1 nurse per each additional 2,000 employees. Additional nurses may be required because of hazards present in a particular plant and to supply service for second and third shifts.* This number will be reduced in inverse ratio to the number of technical and non-professional workers employed in the medical department. Smaller industries (those employing less than 500 workers) which do not have serious occupational hazards may find part-time nursing services adequate.

PART-TIME NURSING SERVICES FOR SMALL INDUSTRIES

Comparatively few employers have felt that full-time nursing service for less than 500 employees is a sound investment. It is being realized to an increasing extent that the number of employees cannot be used as a criterion of the need for an industrial health program. Rather the hazards associated with the working environment and the health problems of the employees are the deciding factors. Effective part-time nursing services have been developed in some cities to meet the needs of the smaller industries through utilization of community nursing agencies or through several plants sharing the services of one nurse. Frequently such part-time service has demonstrated the extent of service needed. In some instances the part-time service has consequently developed into a full-time service, and in other instances the part-time service has been adequate to meet the needs of the plant.

It was recommended that *the use of part-time nursing service should be extended, particularly in plants employing less than 100 workers.* It was further

recommended that *local industrial nursing organizations cooperate with the state industrial hygiene divisions in giving guidance to individuals or agencies which may be utilized in providing such services.*

SUMMARY

The above report of the nation-wide survey conducted by the Committee to Study the Duties of Nurses in Industry serves as an initial attempt to define industrial nursing. Data concerning the nursing service were obtained from 924 industrial establishments employing approximately 2,500,000 workers and located in 36 states and the District of Columbia.

Of the 924 plants, 868, or 95 per cent, employed one or more full-time graduate registered nurses. A total of 3,027 nurses, or about one-third of the registered industrial nurses in the country, were at work in these establishments. Twenty-two of the remaining plants employed nurses part time, and 34 utilized only practical nurses or first aid attendants.

Duties of the full-time nurses were classified into eight general groups: (1) Nursing care and treatment of occupational injuries and illnesses and emergency care of non-occupational illnesses; (2) assistance with medical examination of workers; (3) participation in the health education program; (4) assistance with safety education and accident prevention; (5) assistance with plant sanitation; (6) participation in plant welfare programs; (7) home nursing service; and (8) records and reports. While these classifications serve in a general manner to delineate industrial nursing, a true definition of the profession will not be possible until further standardization of duties is achieved.

Recommendations of acceptable practices in industrial nursing have been made by the Advisory Group of indus-

trial nurses appointed to consider the reported data in light of their own knowledge and experience in this special field. Briefly, the major recommendations are as follows:

1. A nurse working under the direction of a full-time physician should have written procedures for her guidance. All other nurses should have written standing orders.
2. Where two or more nurses are employed, one nurse should be designated as in charge.
3. The medical department, regardless of size, should be responsible to an executive of the industrial establishment.
4. Nursing assistance in the medical examination, both preplacement and other types, should include six specific activities. (See page 870.)
5. When the volume of special technical services requires the time of one individual, a technician rather than a nurse should be employed.
6. The nurse's participation in the plant health education program should be extended and improved. (See page 871.)
7. Nurses should take steps to become authorized Red Cross Home Nursing and First Aid instructors.
8. The nurse should not be responsible for the planning or direction of the safety program but should assist in seven specific activities. (See page 872.)
9. The nurse should show an active interest in all phases of plant environment that affect the health and morale of the worker, but direct responsibility for the supervision of plant sanitation should be delegated to other departments whenever possible.
10. Nurses should participate in and promote worker welfare activities, especially in relation to five particular services. (See page 873.)
11. Home nursing service for workers should be provided by the plant.
12. Records and reports are to the industrial nurse what bookkeeping is to the accountant, and an efficient system should be maintained. (See page 874.)

The chief problems in the field of industrial nursing today have been brought about by the very rapid expansion of this service and the marked increase in the number of nurses employed in various war industries. Of the 2,450 full-time registered nurses who

supplied the information, more than two-thirds, or 70 per cent, began their employment between January, 1940, and December, 1942. The lack of standardization already existing in this branch of the nursing profession, coupled with this increase in the number of nurses employed without previous experience or preparation, places a heavy responsibility on the comparatively small number of nurses practising in industry.

The Advisory Group, recognizing the serious import of these problems, has made recommendations which it is believed will promote the best interests of industrial nursing. The major recommendations may be briefly stated as follows:

1. Nurses for industry should be obtained through professional nursing channels only. (See page 875.)
2. A job analysis should be made to depict the responsibilities involved in a particular industrial nursing position, and a salary should be set for the position commensurate with these responsibilities.
3. Staff nurses who are eligible for military service and who may be replaced by nurses not eligible for such duty should be encouraged to enroll for service with the armed forces and should be granted military leave.
4. Non-professional clinic assistants should be employed, in so far as possible, to conserve nurse-power in performing eight specific duties. (See page 876.)
5. One nurse should be employed for up to 300 workers; 2 or more nurses for up to 600 employees; 3 or more for up to 1,000 employees; 1 nurse for each additional 1,000 employees up to 5,000, and 1 nurse for each additional 2,000. Other nurses may be required because of hazards present in a particular plant and to supply service for second and third shifts.
6. The use of part-time nursing service should be extended, particularly in plants employing less than 100 workers.
7. The local industrial nurses' organization should act in an advisory capacity to other professional groups and to state industrial hygiene divisions in regard to the needs in a local industry and the services of the nurses employed therein.

Incidental to the collection of the survey data, certain benefits accrued to the participating groups. The Working Group responsible for gathering the data acquired more knowledge of and interest in this field. Industrial nursing organization was furthered. Also, the nurses most vitally concerned with

the development of industrial nursing were afforded an opportunity to plan for and promote their specialty through serving on the Advisory Group.

NOTE: The committee acknowledges with appreciation the work of Victoria Trasko, Assistant Statistician, National Institute of Health, U. S. Public Health Service, in doing the statistical analyses.

Proposed Report on the Educational and Experience Qualifications of Laboratory Workers*

I. THE GENERAL SCOPE OF PUBLIC HEALTH LABORATORY WORK

Historically the public health laboratory has been basic to environmental sanitation and to epidemiology, and it continues to be a most important fact-finding center of the health department. Because of the long-standing recognition of these functions, the public health laboratory may be regarded as among the most completely stabilized activities of health departments. Nevertheless, both the amount and the kinds of service expected of the laboratory have recently been expanded. Advancing medical discoveries are likely still further to enlarge the volume and the content of the program. It will be conceded that in almost every area of North America more laboratory service could be used with benefit to the public health program.

Extent and Coverage of Laboratory Personnel

The field of public health laboratory service now includes at least 1,300 workers in professional grades, according to a recent review of official agencies only. No satisfactory estimate is available of the number of professional persons engaged in private laboratories. The

present membership of the Laboratory Section of the American Public Health Association is made up of somewhat over 1,000 members and Fellows. The proportion of these in various types of work was recently as follows:

	<i>Per cent</i>
Public health laboratory work.....	37
Clinical and hospital laboratory work..	19
Academic work	22
Industrial laboratory work.....	13
Other types of service.....	9

As to duties performed by public health laboratory workers, there are listed herewith the functions of a public health laboratory and the duties of the workers are readily inferred.

II. THE FUNCTIONS OF A PUBLIC HEALTH LABORATORY INCLUDE:

1. Bacteriologic, serologic, pathologic, chemical, and other examinations to aid in the diagnosis, control, and treatment of communicable and certain non-communicable diseases
2. Bacteriologic, serologic, pathologic, chemical, and other examinations associated with the diagnosis and control of diseases occurring among domestic and wild animals, and transmitted to man
3. Bacteriologic, chemical, microscopic, and other examinations of water, sewage, industrial wastes, shellfish
4. Examination of milk, frozen desserts, and other foods, drugs, liquors, narcotics, etc.
5. Production or provision of diagnostic, prophylactic, and therapeutic preparations, such as sera, antitoxins, toxins, vaccines, etc.
6. Research. Research is an important function of every public health laboratory. It is essential to the development of new and better methods for the control and prevention of disease, and promotes in the staff that critical attitude toward methods and results without which an acceptable standard of work cannot be maintained.

* The Committee on Professional Education of the A.P.H.A. publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

III. THE EDUCATIONAL BACKGROUND

The basic preparation for public health laboratory work should essentially be professional preparation in bacteriology, chemistry, serology and/or parasitology, and in all cases the minimum training should be a college degree, with emphasis on at least chemistry, physics, and biology.

Promotion in responsibility should be based not only on experience but on the expectation that additional academic training will be secured. The ultimate balance between formal training and practical experience will have to be adjusted within each state or provincial system. In general, it is to be expected that an individual will make promotional progress through the classifications given below.

Outline of Training and Experience

In view of the diverse functions of a public health laboratory, the system should be so devised that an individual as he makes promotional progress toward the grade of Director should have:

1. Training in general biology
2. Advanced special training in one or more of the biological sciences, together with the training and the personal qualifications necessary for conducting research in one or more of them
3. Acquaintance with the biology of disease
4. Experience in a public health laboratory such as that described in this report
5. Administrative experience in the various divisions of the laboratory
6. Competence to interpret the place of the laboratory in the whole health program

Personnel Policies Encouraging Career Service in Public Health Laboratory Work

Regarding the titles of positions, it makes little difference what nomenclature is used in a particular laboratory system so long as training to the level of at least the baccalaureate degree is considered a minimum requirement.

However, the term "technician" in related fields has so commonly been applied to persons who do not hold college degrees that it is desirable that the term be avoided in connection with the professional staff of public health laboratories.

Four levels have been provided in the classification of grades used in this report. Local conditions, however, may make it wise to provide a different number of grades. The exact number is immaterial so long as reasonable promotional opportunities are provided.

The unification within one system of all laboratory services relating to the protection of the public health is desirable, but at present only federal, state, and large municipal laboratories approach organization of this character. This report deals primarily with the larger laboratory systems. It is recognized, however, that most systems of laboratory service will contain smaller laboratory units with a staff of but one or two persons in whom must be combined several of the skills herein described. It is essential to have such smaller units incorporated into larger systems, such as that for a state, which will provide uniformity of standards and suitable promotional opportunities.

It is recognized that no single pattern can apply throughout North America, and it is well known that several states or provinces have well matured systems based on quite different patterns. It is not intended that these systems should be disturbed so long as they accomplish the purposes of high professional achievement. Rather it is desired to provide a broad framework for the guidance of interested persons in situations not enjoying the benefits of such established patterns.

This report should be thought of as a yardstick for a state, provincial, or territorial system of laboratory service, rather than as a pattern for an individual laboratory. It assumes that the

laboratory is a part of a well organized health department, operating under a modern merit system, and that the laboratory, together with all other divisions, is responsible for a well integrated service, both within the department and within the community.

IV. QUALIFICATIONS FOR VARIOUS GRADES OF LABORATORY WORKERS

The specific training and experience described below are regarded as the minimum qualifications for adequate laboratory service. These qualifications are not intended to be retroactive, but to apply to the selection of new personnel as positions become available.

A. Director

The director of a public health laboratory as defined in this report should possess those qualities of personality and character necessary to insure the honest and successful prosecution of scientific work. He should have an educational background in the biologic sciences at least equivalent* to the requirements for a doctorate in biological science, public health, or medicine as prescribed by a university belonging to the Association of American Universities or a medical school approved by the American Medical Association.

In addition he should have:

- a. Five years' postgraduate practical experience and training in a laboratory of such size that experience may be obtained in the various biological sciences applicable to health and sanitary problems. Not less than two of the five years of postgraduate training and practical experience should have been devoted to training

in general and special laboratory technics applicable to the recognition of disease in the human family and disease in animals transmissible to man, and in health and sanitary problems.

- b. At least two years' administrative experience in a properly directed public health laboratory of such size that experience in the coördination of various laboratory functions may be obtained.

B. Assistant Director

He should have the formal educational qualifications outlined above for the Director. In addition he should have at least three years of practical experience and training in general and special laboratory technics as provided for the Director.

C. Pathologist

a. Principal Pathologist

He should have graduated from a medical school approved by the American Medical Association, and should have postgraduate training and experience equivalent to that prescribed for certification by the American Board of Pathology. Essentially this requirement is for five years of special training and experience after graduation from medical school, made up of an internship in an approved hospital, study of pathology for not less than three years in a recognized institution, and at least one year of further training or practice in pathology.

b. Associate Pathologist

He should have graduated from a medical school approved by the American Medical Association, and should have had not less than one year devoted to practical experience in the study of general and special human pathology and related medical subjects.

* The word "equivalent" as used in this report is for the purpose of assuring that, under special conditions, certain of the requirements relating to formal education may be waived, provided however that the qualifications of the applicant equal or exceed those specified.

D. Bacteriologist**a. Principal Bacteriologist (or Serologist)**

He should have an educational background in biological sciences equivalent to the requirements for a doctorate prescribed by a university belonging to the Association of American Universities, with a major in bacteriology or immunology, and at least two years' practical experience in a public health laboratory.

b. Associate Bacteriologist (or Serologist)

He should have an educational background equivalent to a Master of Science degree prescribed by a university belonging to the Association of American Universities, with a major in bacteriology or immunology, and at least one year of practical laboratory experience.

c. Senior Assistant Bacteriologist (or Serologist)

He should have an educational background equivalent to a Master's degree prescribed by a university belonging to the Association of American Universities, with a major in bacteriology or immunology.

d. Junior Assistant Bacteriologist (or Serologist)

He should have an educational background equivalent to a Bachelor's degree prescribed by a university belonging to the Association of American Universities, with a major in bacteriology or related sciences.

E. Chemist**a. Principal Chemist**

He should have an educational background in biological sciences equivalent to the requirements for a doctorate prescribed by a university belonging to the Association of American Universities, with a major in chemistry and at least two years'

practical experience in a public health laboratory.

b. Associate Chemist

He should have an educational background equivalent to a Master of Science degree prescribed by a university belonging to the Association of American Universities, with a major in chemistry and at least one year of practical laboratory experience.

c. Senior Assistant Chemist

He should have an educational background equivalent to the requirements for a Master's degree prescribed by a university belonging to the Association of American Universities, with a major in chemistry.

d. Junior Assistant Chemist

He should have an educational background equivalent to a Bachelor's degree prescribed by a university belonging to the Association of American Universities, with a major in chemistry.

F. Parasitologist**a. Principal Parasitologist**

He should have an educational background in the biological sciences equivalent to the requirements for a doctorate prescribed by a university belonging to the Association of American Universities, with a major in parasitology and at least two years' practical experience in a public health laboratory.

b. Associate Parasitologist

He should have an educational background equivalent to a Master of Science degree prescribed by a university belonging to the Association of American Universities, with a major in parasitology and at least one year of practical laboratory experience.

c. Senior Assistant Parasitologist

He should have an educational background equivalent to the requirements for a Master's degree prescribed by a university belonging to the Association of American Universities, with a major in parasitology.

d. Junior Assistant Parasitologist

He should have an educational background equivalent to a Bachelor's degree prescribed by a university belonging to the Association of American Universities, with a major in parasitology.

TABULAR RESUMÉ OF TRAINING AND EXPERIENCE SUGGESTED FOR VARIOUS GRADES IN THIS REPORT

<i>Position</i>	<i>Essential Degrees</i>	<i>Major Academic Emphasis</i>	<i>Years of Prior Experience Essential</i>
Director	Doctorate in science, public health or medicine	Medical and biological sciences	5, with minimum of 2 years in a public health laboratory
Assistant Director	Doctorate in science, public health or medicine	Medical and biological sciences	3
Principal Pathologist	M.D.	Medicine and pathology	5
Associate Pathologist	M.D.	Medicine and pathology	1
Principal Bacteriologist	} Doctorate in science, public health or medicine	Bacteriology	2
Principal Serologist		Serology	2
Principal Chemist		Chemistry	2
Principal Parasitologist		Parasitology	2
Associate Bacteriologist	} Master's degree	Bacteriology	1
Associate Serologist		Serology	1
Associate Chemist		Chemistry	1
Associate Parasitologist		Parasitology	1
Senior Asst. Bacteriologist	} Master's degree	Bacteriology	..
Senior Asst. Serologist		Serology	..
Senior Asst. Chemist		Chemistry	..
Senior Asst. Parasitologist		Parasitology	..
Junior Asst. Bacteriologist	} Bachelor's degree	Bacteriology	..
Junior Asst. Serologist		Serology	..
Junior Asst. Chemist		Chemistry	..
Junior Asst. Parasitologist		Parasitology	..

EXPLANATION OF NEGATIVE VOTE ON PROPOSED REPORT ON THE EDUCATIONAL
AND EXPERIENCE QUALIFICATIONS OF LABORATORY WORKERS

The Proposed Report has my approval, except for the failure to include in the qualifications for a director the degree of Doctor of Medicine. It is my opinion that public health laboratories will continue to have increasing obligations in connection with clinical medicine; that a medical degree is essential background for a director in order that a public health laboratory may function adequately.

The question of requiring graduation in medicine as a qualification for laboratory directors in New York State was carefully considered several years ago

by the Public Health Council of New York State, and in 1937 this requirement was enacted into a regulation. As a member of the Council I voted for this provision and as Commissioner approved the Council's action.

I have found no reason for changing my opinion since that time, and feel that it would be inconsistent for me to subscribe for any lower qualifications in a report to the Association.

Otherwise, the Report has my approval.

EDWARD S. GODFREY, JR., M.D.

THE WESTERN BRANCH MEETING—1943 STYLE

Readers of the *Journal* will recall that the usual meeting of the Western Branch which was scheduled for May, 1943, was cancelled because of the lack of a suitable place and lack of man power sufficient to operate such a gathering of 800-900 persons at one time. Nevertheless there was a realization on the part of the officers of the Western Branch that there were more compelling reasons this year for an annual meeting than ever in order that the public health professions may continue to be informed about and integrated with the movement in this critical year. It was on this account that the American Public Health Association has satisfaction in having been able to organize substitute meetings to replace the Branch meeting, and by this means to reach many more of the workers themselves than would have been possible had the annual meeting been held in San Francisco as planned. The total attendance exceeded 2,850, mostly professional workers.

An invitation had been extended some months previously to Dr. Robert Hughes Parry, Medical Officer of Health of the City of Bristol, England, and Professor of Public Health at the University of Bristol, to be in the United States during the late spring, and it was possible to organize a series of meetings around this visit of Dr. Parry and the natural interest of all health workers in the experiences of those who have been through a severe blitz. Fortunately, Dr. Parry proved to be an ideal person for this interpretation to Americans and Canadians, and he was a delightful travelling companion for the team members who found it possible to attend some or all

of the state and regional meetings which resulted.

With Dr. Parry was Dr. John L. Rice, immediate past-President of the A.P.H.A. and Commissioner of Health in New York City, 1934-1942; Dr. Erval R. Coffey, Assistant Surgeon General, U. S. Public Health Service, Washington, D. C., and formerly State Health Officer of Washington State; Dr. Don W. Gudakunst, Medical Director of the National Foundation for Infantile Paralysis, New York, N. Y., and formerly State Commissioner of Health in Michigan. Also Dr. Albert McCown, Medical Director of the American Red Cross, Washington, D. C., and formerly of the staff of the U. S. Children's Bureau; Dr. Nathan Sinai, Professor of Public Health of the University of Michigan; Dorothy Denning of the Merit System Unit, A.P.H.A., formerly General Director of the N.O.P.H.N.; and Dr. Edith Sappington of San Francisco, representing the U. S. Children's Bureau. For part of the meetings it was possible for Dr. Karl F. Meyer, Director of the George Williams Hooper Foundation, University of California, to be present. Dr. Meyer is President-elect of the Western Branch. Dr. Carl E. Buck, Field Director of the A.P.H.A. Committee on Administrative Practice, joined the team in California. Raymond Greenman, Field Representative, American Social Hygiene Association, for the Ninth Service Command, joined the group in New Mexico. Dr. Reginald M. Atwater, Executive Secretary of the A.P.H.A., directed the team. The programs were locally planned and carried out.

Dr. Parry had been in attendance at

public health meetings in Connecticut, Iowa, Kansas, Missouri, Indiana, Wisconsin, and New York prior to May 13 when the team left the East. The first meeting on the circuit was in Chicago, where the Illinois Public Health Association held an annual meeting. The arrival of the team was perfectly timed with the advancement of a new permissive health unit bill before the Legislature which is reported to have passed the Senate unanimously and, at this writing, is waiting for action by the House. This bill, sponsored by the State Health Department, will give Illinois legal opportunity for the first time to set up county units. A similar fortunate circumstance at Lincoln, Neb., made the visit of the team significant because a bill before the unicameral legislature was ready for a vote, and favorable action later followed.

Entering the territory of the Western Branch at Denver, the team enjoyed a stop of one day with public health workers of Colorado, where critical problems were brought out for consideration in a problem-solving panel in which the experience of the entire team could be mobilized. The attendance was at least as large as the usual meetings of the Colorado Public Health Association.

The next stop was at Albuquerque, where the New Mexico Public Health Association had a two day meeting, also well attended and generally agreed to have been unusually fruitful. A considerable number of the local staff had never had the opportunity to attend a Branch meeting or other larger gatherings of professional workers in public health, and the members of the team were left in no doubt as to the appreciation felt by the staffs in New Mexico.

The Arizona Public Health Association held a regular meeting of two days in Phoenix and it was said to have been the best attended of any meetings ever

held by the state group. In these states it seems to have been true that at least ten times as many persons were able to attend as would have been able to get to San Francisco for the Branch meeting, even in a normal year.

The meeting of the Southern California Public Health Association was held in Pasadena under the Presidency of Charles Arthur, Health Officer of Pasadena, and was reminiscent to many of the annual meeting of the A.P.H.A. held in the same place in 1934. More than 500 were in attendance and the problem-solving panel in Pasadena boasted 12 participants, including Dr. W. L. Halverson, the new State Health Officer. There was no doubt of the success of the meeting, which in itself was larger than some recent meetings of the Branch in normal years.

Berkeley was chosen as the place for the meeting of the Northern California group, and nearly 500 registered during the two days of meetings, when local talent was used with the national leaders to cover a very dynamic field of interest in this most dynamic state. Here as in Albuquerque, Phoenix, Pasadena, and Seattle, the contributions made by Dr. Meyer and his consultants in medical research were particularly appreciated. A panel on medical care was an outstanding feature in Berkeley.

Subsequently meetings were held in Portland, Ore., in Seattle, Wash., and in Boise, Ida., for most of the team members. A later meeting of the Montana group in Bozeman was planned and some of the team were scheduled to attend meetings near the Mexican border in Juarez and El Paso during June.

Dr. Meyer, President-elect of the Western Branch, has suggested to some of the state meetings that this pattern of a travelling team may be useful for the future as an alternate for Western Branch meetings, which at best are a considerable distance from some parts

of the Branch territory. In a year like 1943 it was generally agreed that the team idea brought leaders in touch with local problems and gave local workers some inspiration more successfully than would have been possible with one meeting of the Branch in any available city.

An account of the blitz in Bristol as presented by Dr. Parry will become available shortly through the columns of the *American Journal of Public Health*, together with selected articles growing out of these regional meetings and bearing especially on the current problems of the professional worker.

The attention of A.P.H.A. members in the western states has been called to the circumstances under which the 72nd Annual Meeting of the A.P.H.A. and the War Conference will be held in New York City, October 12-14. The Executive Board has directed that there shall be no encouragement of travel for those at a distance greater than an overnight trip from New York, excepting for selected delegates who can systematically report on the War Conference to their colleagues. These state meetings have given an opportunity for the selection of these delegates and for early planning to avoid the difficulties of travel as they now exist.

Readers of Credit Lines will be interested in the impressions of the 1943 pattern of program and meeting as expressed by various members of the team:

Dr. Parry's Impressions

After two months spent in almost continuous travel and visiting among health workers in the United States, Dr. Parry was asked to summarize his impressions about his visit and about the health activities which he had seen. He said: "It makes an enormous difference to be a member of a party on such a tour as that which I have just

taken across the States and back. This method puts one completely at home as he travels. I know that there are some thrills in travelling alone, but one can have one's fill of that. I prefer the pleasure of association with those of similar minds.

"You Americans make it easy for a stranger to make himself at home, even where there may be marked differences of opinion. It is the same knack of a lawyer who makes one confess beyond his intent. It reminds me of the lawyer who asked the man seeking damages for injury to his arm how high he could raise his injured arm and then to show the jury how high he could lift it before it was injured.

"I am impressed by the fact that you in America have accumulated all workers into an inclusive organization, the American Public Health Association. This is a unique Americanism. Neither the Royal Sanitary Institute nor the Society of Medical Officers of Health attracts the subordinate workers as you do here. The opportunity of meeting on a common ground and with those of comparable status seems to me very interesting and fruitful.

"You have here a striking enthusiasm for travelling long distances in order to attend meetings. Your concept of distance is different from ours. Travel of 100 miles seems to us enormous, while you think nothing of 2,000 or even 4,000 miles. I am a believer in the American attitude toward conferences.

"There is a vast difference between American administrative procedure and ours in England. Your executive officer seems to be so independent once he has the authority, whereas with us the executive acts as the agent or the servant of the committee. There are, of course, advantages as well as disadvantages in both methods. The authority of the public health officer here is much greater, but his individual re-

sponsibility is also greater and consequently there is a greater strain on your health officers.

"Security of tenure has different effects on different types of people. Security of tenure in office is not necessarily a good thing. In fact, nothing ever does take the place of selecting the right person for the job, either in your country or in ours. The wrong person with security of tenure is a greater menace to the service than he would have been without security, but the right man in the right post can do his work with a better heart and greater energy when he has security.

"However, the similarities between your health service and ours are equally striking. Your general attitude toward social welfare, the stress you lay upon the home, on environmental hygiene and on health education are all similar to our approach. But the way you serve your food and the natural advantages that you have for variety of food result in a more varied and satisfactory diet than ours in Britain."

Dr. Karl Meyer's Impressions

It will be no surprise to those who know Dr. Karl F. Meyer of San Francisco that his presence with the team in Albuquerque, Phoenix, Pasadena, Berkeley, and Seattle added much to the interest and value of the programs. His first hand familiarity with the medical problems of the West and his experimental approach to a great variety of conditions involving animals as well as man made it possible for him to throw valuable light on many of the questions asked of the panel. At least the other members of the team gained immeasurably from his contributions, and in this we think we were no different from the rest who attended.

Dr. Meyer was encouraged to set down some observations on the plan of using this team of travelling speakers instead of the conventional type of

meeting. He said: "The very large attendance has made it possible to bring the message to many people and as a device this method compares favorably with the usual type of meetings. The programs this year had the character of postgraduate instruction of the refresher course type. Several persons told me that they found themselves definitely motivated by this program which used panel discussions prominently instead of the usual read manuscripts.

"The comradeship which was developed among the members of the team is one of the most treasured possessions to remember. I have never seen so diversified a group live so fruitfully with each other in spite of the confined space incident to travel this year and the other travel difficulties."

Dr. John Rice's Impressions

"There were four things that impressed me on the A.P.H.A. group western trip. First the eagerness and enthusiasm of the health workers in the various states — eagerness to keep abreast of public health in wartime and enthusiasm over the importance and value of the work they are undertaking. Second, the need for more money and more man power to make possible the wider application of our public health knowledge. Third, the need for strong leadership by the official state and local health agency. Fourth, the importance of the utilization of all available health forces in a united program. Such a program may well include federal assistance, that of the nonofficial agency as well as volunteer help.

"The experience of this trip raises the question in my mind as to whether or not this undertaking attempted as a war emergency procedure may not contain within it a technic of value for normal times for the promotion of public health and in holding closer together the component parts of the A.P.H.A.

"An extra premium resulting from this trip was the extension of the feeling of confidence and understanding between the various agencies through their representatives on the tour. Besides this, public health in England and the United States moved closer together through Dr. Parry, the representative from Bristol, England."

Dr. McCown's Impressions

"My overall feeling at the end of this trip is one of gratification and satisfaction that the American Red Cross was invited to participate with this group of outstanding public health leaders in their visit to meetings of public health associations in ten states. It gave the Medical Director of the American Red Cross an opportunity to meet health officials in several states and to discuss with them the channels of better integration of the health activities of local chapters of the American Red Cross with the local health departments.

"Everywhere I sensed a realization that in these emergency times there should be close coöperation. In their health activities the Red Cross Chapters need sound medical advice, and in community activities the well organized local health department should be equipped to render such advice. Through their various training programs the local chapters of the Red Cross have trained large numbers of volunteers in first aid, nurses' aids, home nursing, and nutrition. This group constitutes a tremendous backlog of individuals who have shown their awareness of health needs and, through participation in training courses, their desire to be of service. It would seem desirable therefore that through local consultation and agreement between the health agency and the local chapter of the American Red Cross, these volunteers, having been trained, may be given an opportunity to serve.

"A feature of special interest was the round table conducted at the meeting of the Northern California Public Health Association in Berkeley on medical care, which was organized by Milton Rose, M.D., Medical Director for the Pacific Area of the American Red Cross, who acted as chairman.

"On the personal side, the Director found a spirit of genuine coöperation and friendliness and had an opportunity to make lasting new friendships and to cement old ones. It was a privilege to come to know, in the intimate contact of a three weeks' tour, the distinguished but modest and lovable visitor from Bristol, Dr. Robert Hughes Parry.

"It was specially appropriate that the agency which arranged this series of meetings was the professional society of public health workers, and the representative of the American Red Cross wishes to express his appreciation of the splendid way in which the trip was organized and managed."

Miss Deming's Impressions

"To me the most outstanding feature of these state-level national meetings was the presence of local lay people. Non-professional leaders in community life who would never travel to a national convention or even to a Western Branch meeting, heard their own home problems discussed by representatives from the federal government, the American National Red Cross, and five voluntary national health agencies. It was a chance to take their questions 'right to the top' without spending even postage putting themselves on record. The informality and good natured interchange among the experts in all the discussions made for friendly feeling and promoted the impression that the nationals were after all 'just folks,' trying to pull together for the good of all, especially for the people in the state in which they were meeting. Citizens learned quite a lot about how

their way of doing things stacked up against the best standards, and more than one person in the audience heard something entirely new about his local health department for which he was paying taxes.

"As a membership promotional device I cannot think of a better! One elderly nurse said to me, 'I've been a member of the A.P.H.A. for ten years, but this is the first time I've ever been able to get to one of your meetings. I live three hundred miles away. I'll always remember this meeting—(she referred to a particularly lively round-table discussion)—I got my question answered!'

"I think it should also be said that the ten or more staff representatives of the national agencies travelling together did quite a little housecleaning! Questions as to certain national policies of each agency—long misunderstood or misinterpreted, got cleared up, and once in a while one would hear an exclamation, 'That's a good idea! We ought to do that,'—or, generously, 'You're absolutely right. We don't go about that in a constructive way.'

"Many people spoke of the practicality of this plan of meeting, pointing out the saving of expense in combined staff travel (taxi service for example), the conveniences to the local hosts in entertaining a group instead of successive national visitors, and the chance for small conferences with several national representatives at once.

"All agreed that the down-to-the-bedrock level of the discussions of local questions, as compared to the over-all generalizations necessary in regional or national meetings, was a joyful relief. It should also be said that frequently the question as to a specific, factual situation existing four blocks away was harder for the visiting team to answer than the glib quoting of an accepted policy applicable anywhere in the United States.

"Finally, I am sure the impression left on the local groups is invaluable as an asset of good will—that the A.P.H.A. is ready to come to them when they cannot come to New York, that it has had the courage to experiment with a new 'way of life' in annual meetings and that it is able to bring together a group of health workers worth listening to, helpful—and in the case of Dr. Parry, our drawing card—inspiring."

Bristol's Method of Treating Verminous Heads

Considerable interest was expressed at the meetings addressed by Dr. Parry in the method which he described for treating lousiness, especially among school children, which was developed during the battle of Britain. The method adopted by his department is described in a memorandum dated June 25, 1942.

A single application of 40 per cent lethane brilliantine is thoroughly applied to the hair, followed one week later by a thorough soap and water washing. Immediately after washing, the hair is dampened with dilute acetic acid and combed to remove all dead nits. There is evidence that this method will not only clear the head of vermin but will protect from further infestation for at least a week.

The lethane brilliantine solution formula is as follows:

40% solution lethane 384 special	32 oz.
Liquid paraffin lev. ad	½ gal.

The lethane is a derivative of arsenic preparations made in the United States and shipped to Great Britain for use as insect sprays.

Bristol's Method of Treating Scabies

A similar memorandum to doctors and nurses quotes from a publication of the Ministry of Health on the treatment of uncomplicated cases of scabies,

as well as the disinfection methods and rules for exclusion from school.

Treatment—Scabies can be efficiently treated either with sulfur ointment or with benzyl benzoate. Benzyl benzoate emulsion (25 per cent) is the preparation of choice, and for uncomplicated cases of scabies the treatment of patients during the present emergency should be standardized as far as possible:

(a) The patient is first given a slipper bath in which he is told to soak for 10 minutes; alternatively a shower bath for 5 minutes would suffice. He then soaps himself freely using, if necessary, a rough flannel but not a scrubbing brush, and rinses the soap off.

(b) The patient is then dried and, in a room adequately warmed, benzyl benzoate is applied over the whole body, from the neck downward, with an ordinary flat paint brush $1\frac{1}{2}$ –2 inches wide. The application is allowed to dry and the patient puts on clean underclothes.

(c) Two such treatments should be

given, either on successive days, or within a period of 8 days.

Where a case of scabies occurs in a house, the whole family should, if possible, be treated at the same time.

Disinfection — Clothing, particularly clothing worn next to or touching the skin, and articles of bedding with which a patient comes in contact, such as sheets or blankets, should be properly disinfected if the necessary apparatus is available. Otherwise, underclothing, towels and sheets at least should be washed and aired and outer clothing ironed with a hot iron. Blankets may be ironed or hung in a warm dry place for 2 days.

Exclusion from School—After the first treatment with benzyl benzoate there is no medical reason for excluding an uncomplicated case of scabies from school.

The formula for the benzyl benzoate solution is as follows:

Benzyl benzoate	25 gm.
Lanette Wax SX (emulsifying agent)	2 gm.
Water	100 ml.

BOOKS AND REPORTS

Doctor in the Making. *The Art of Being a Medical Student*—By Arthur W. Ham and M. D. Salter. Philadelphia: Lippincott, 1943. 179 pp. Price, \$2.00.

This admirable little book is the result of investigations by a committee of the faculty of the University of Toronto, the object of which was to determine why the records of certain students were not reasonably in accord with the predictions based on their aptitude tests and their scholastic records. There were enough examples of discrepancy between prediction and accomplishment to show that ability and academic preparation do not guarantee success. As a result of the inquiry the committee became advisory rather than investigatory. The authors point out that the amount of information placed before the medical student of today is appalling and the steady stream of knowledge can be mastered only by a mind skilled at learning. This seems to be the first instance in which a university has recognized the duty of teaching students to become competent students in addition to teaching them how to become competent physicians.

The authors are evidently masters of their subject and every page contains good advice. They stress the value of premedical sciences regardless of the field of medicine the student wishes to pursue. They have the faculty of putting things straight from the shoulder. For example, "Knowing an anatomy textbook by heart does not make a good anatomist any more than memorizing the Bible makes a good Christian." We wish space allowed many more quotations. There is much in the book that the professor should take to heart also. A good example of this concerns the organization of one's total

knowledge with each bit in its proper compartment. This may become almost a disease, and such people, including some doctors, "do not hold conversations with their fellow men—they deliver lectures." "The signs of this disease are an ability and a willingness to bore people with long discourses on all subjects."

Much of the book is summed up in Part Three. The authors lay stress on the responsibility of every medical student to become a cultured civilized person in addition to being well versed in the medical sciences. It is the duty of medical schools to help in the cultural development of their students. Some schools have already added some subjects in arts courses for this purpose, though the already crowded curriculum makes it difficult. On the last page is a charming tribute to the old-fashioned country doctor who was respected for his humanity as well as his tolerance. Though "he was suspected of believing in evolution and known sometimes to consort with sinners, he was nevertheless beloved and respected."

The illustrations are excellent. It is hard to commend this book too highly both to students for whom it is written, and to professors. The one criticism is that short as it is, it is still too long for the average student with his crowded curriculum and the many outside activities often forced on him.

MAZÏCK P. RAVENEL

Manual of Industrial Hygiene and Medical Service in War Industries—By Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service, William M. Gajafar, D.Sc., Editor. Philadelphia: Saunders, 1943. 508 pp. 20 ill. Price, \$3.00.

This timely and important manual

on industrial hygiene is the result of the joint efforts of 16 specialists of the National Institute of Health. It was prepared at the suggestion of the Committee on Industrial Medicine of the Division of Medical Sciences of the National Research Council. It is designed as a source of current and reliable information for industrial physicians, industrial engineers, industrial hygienists, and others who are interested in this highly important, rapidly expanding, and scientifically complex field of public health endeavor.

It is estimated that in 1943 there will be 22 million essential war workers and 18 million others who will be contributing to their basic requirements for healthy living such as food supply, housing, transportation, public utilities, etc. The satisfactory health of those industrially employed has never been of greater importance to the national welfare. The problem has been aggravated by the removal of medical and engineering personnel from industry for direct military service and by the crowding, poor housing, inadequate schools, recreation, and other welfare services, increased mental and nervous strain, increased fatigue, and the introduction of new and serious hazards that have attended the industrial expansion of the national war effort.

Industrial health touches the life of the community in all of its aspects. It cannot be solved by industry alone. It is the joint responsibility of the industry and the community. Unfortunately, it has been a relatively neglected field of public health endeavor. The rewards of intelligent, consecrated efforts on an extensive scale in the field of industrial health should be reflected in increased longevity, prevention of communicable disease, prevention of accidents and resulting disabilities, curtailment of absenteeism, and promotion of sound nutrition, good medical, dental, and nursing care, sanitary

housing, satisfactory environmental sanitation, and positive health.

The book is divided into three parts. Part 1 deals with the organization and operation of the medical, nursing, dental, and emergency treatment facilities necessary for industry. Part 2 deals with the prevention and control of disease in industry and includes chapters on occupational diseases, occupational dermatoses, control of the atmosphere in the working environment, control of respiratory and venereal diseases, industrial psychiatry, industrial fatigue, health education, nutrition, and community as well as plant sanitation. Part 3 deals with the man power problem including the maximum use of man power, women in industry, and absenteeism.

The book is a splendid contribution to essential working knowledge in the field of industrial health work. It can be highly recommended as authoritative, as exceedingly useful, and as of the utmost importance to the success of the national war effort.

MURRAY P. HORWOOD

The Pasteurization of Milk—By G. S. Wilson. New York: Longmans, Green, 1942. 212 pp. Price, \$5.00.

The author, a professor of bacteriology as applied to hygiene, University of London, has described the chief physical, chemical, and bacterial changes brought about by the pasteurization of cow's milk in equipment designed to hold it at about 145° for 30 minutes. The effect of pasteurization on the nutritive value of milk, milk taste, cream line, fertility of animals fed on a milk diet, the destruction of pathogenic organisms, and the extent of milk-borne disease is described in meticulous detail.

The 10 page bibliography is one of the best ever seen on subjects related to why milk should be pasteurized and why pasteurization should not be ob-

jected to, and it indicates the extent to which the author has gone to secure information from available sources in all parts of the world.

There is much repetition in the book but this does not detract from its value. The summaries at the ends of sections or parts thereof are useful.

There is little useful information in the book as to *how* milk should be pasteurized. It can be recommended as good reading for all people who oppose pasteurization and all who wish to review the literature in connection with the historical background of the subject. The book would probably not be particularly useful to the sub-professional health worker unless he wishes to refurbish his repertory of arguments in favor of pasteurization. E. C. GARTHE

Social Work Year Book 1943—
Russell H. Kurtz, Editor (7th issue).
New York: Russell Sage Foundation,
1943. 764 pp. Price, \$3.25.

Here is a time-saver for the health officer or other administrator in public health, who, busy though he may be with his daily tasks, nevertheless desires to keep abreast of new knowledge and developments within the various areas of his own general field of interest and in closely related fields. This is how the volume would help him to do that:

It reports succinctly in a series of articles the current status of organized activities in particular areas in the field of public health, and each such article is written by a recognized leader in his or her specialty. These particular areas are Tuberculosis, Social Hygiene, Maternal and Child Health, Social and Health Work in the Schools, Mental Hygiene, Medical Care, Medical Social Work, Crippled Children, Blindness and Conservation of Sight, the Deaf and the Hard of Hearing, Psychiatric Social Work, Public Health Nursing,

and one on Public Health generally. Further, there are articles on topics that have much in common with the public health movement, such as the following: Housing and City Planning, Behavior Problems, Adult Education, Parent Education and Child Development, Publicity and Interpretation in Social Work, Rural Social Problems, Labor Legislation and Administration, and Community Organization for Social Work.

The book contains two major divisions: Part One, consisting of 78 signed articles, written by authorities on the aforementioned topics and many others in social work, in a comprehensive meaning of that term, with a list of selected references to the literature of each of these subjects; and Part Two, consisting of 4 directories of national and state governmental agencies and national and state voluntary agencies, whose programs are concerned with or relate to the topical articles constituting Part One.

The *Social Work Year Book* is issued biennially, and this is the seventh of the series. Quite naturally this 1943 edition emphasizes the important events and developments that have occurred in the two year period since the preceding edition was issued, especially those relating to the national defense and war programs.

The volume is excellently indexed. The Index includes in a single alphabetical list the titles of the 78 topical articles in Part One, cross-references to subjects discussed in these articles, names of the governmental and voluntary agencies included in Part Two, and cross-references to the subjects with which these agencies are concerned.

Your reporter believes that the objective of the publisher and editor has been abundantly realized—the presentation of a concise up-to-date encyclopedia of work in the fields of social welfare, public health and kindred mat-

ters—and he recommends that health officers and other health work executives find a place for it on their desks as a ready, convenient source of current information on many subjects with which they are concerned and on others in which they are or may well become actively interested.

It is the opinion of the reviewer that the title of the volume is not adequately descriptive of the breadth of its contents, for the term "Social Work" is still quite narrowly interpreted by many persons as relating chiefly to the case work process for dependent, neglected, disadvantaged, and delinquent individuals and families. He is disposed to believe that more persons would be induced to acquire this excellent compendium of information if a more broadly descriptive title could be found for it.

GEORGE J. NELBACH

The Epidemiology of Rheumatic Fever and Some of Its Public Health Aspects—*By John R. Paul, et al. (2nd ed.) New York: American Heart Association, 1943. 163 pp.*

In this monograph Dr. Paul presents a lucid review of the literature of the past decade regarding the epidemiology of rheumatic fever and its public health aspects. American, British, and Scandinavian publications have been included, as well as his own extensive investigations.

The thirteen chapters are presented in three parts. In addition there are an appendix and a selected bibliography. In Part I, a concise consideration is given to definition and nomenclature in the first two chapters, as well as a brief historical review of the epidemiology of rheumatic fever. In chapters 3 and 4 is documented the evidence for the "Epidemiological Associations Between Rheumatic Fever and Acute Hemolytic Streptococcal Infections," concluding in a general summary, part of which follows:

As one looks broadly at present concepts of the relationship between streptococcal infections and rheumatic fever, which have been reviewed in the last two chapters, it seems obvious for clinical, immunological, and epidemiological reasons that hemolytic streptococcal infections have something to do with rheumatic fever. The strongest evidence in this association is the fact that certain epidemics of so-called streptococcus sore throat, tonsillitis, and perhaps scarlet fever are followed more or less irregularly by groups of cases and even "epidemics" of rheumatic fever.

In Part II, chapters 5-9, there is presented a critical review of some of the most important epidemiological aspects of the disease, comprising the following considerations:

- Chapter V. The Frequency of Occurrence and General Importance of Rheumatic Fever
- Chapter VI. Geographic Prevalence and Climatic Influences
- Chapter VII. Age, Sex, and "Racial" Prevalence
- Chapter VIII. Living Conditions
- Chapter IX. The Rheumatic Family

In Part III there is a timely consideration of the public health aspects of rheumatic fever, with a general summary. Also included are a chapter on "Lines Along Which Public Health Procedures May Develop," by Dr. David D. Rutstein, and a chapter by Dr. T. Duckett Jones on "General Considerations for the Long-term Care of Patients with Rheumatic Fever and Rheumatic Heart Disease." In an excellent, concise general summary, the following provocative concept is of particular interest:

Most of the general statements which appear in this review . . . are based on the assumption that rheumatic fever is a specific disease, or clinical entity. There is room for argument as to the validity of this assumption, particularly as it has been repeatedly brought out in this review, that rheumatic fever is a disease which is closely related to hemolytic streptococcal infections.

The appendix, "Special Methods for Use in the Study of the Epidemiology

of Rheumatic Fever and Its Public Health Aspect," is an important contribution to the value of the volume. Particularly helpful is Dr. Thomas D. Dublin's section on the "Methods of Determination of Incidence and Prevalence of Rheumatic Fever."

This monograph is a much needed addition to the literature on rheumatic fever and will be welcomed by students of the disease. MAY G. WILSON

The Freezing Preservation of Foods—By Donald K. Tressler, Ph.D., and Clifford F. Evens, B.S. New York: Avi Publishing Co., 1943. 763 pp. Price, \$8.00—Domestic, \$8.25—Canada and foreign.

The present volume is essentially a greatly enlarged and improved re-writing of the authors' book *The Freezing Preservation of Fruits, Fruit Juices and Vegetables* which was written six years earlier, and contains a vast amount of new material. Since that time great progress has been made in the application of freezing to all classes of foods, and this volume deals with principles and with practice. In its 21 chapters it covers the theories and the technical aspects of freezing fruits and fruit juices, vegetables, meats, fish, shellfish and dairy products, and discusses in considerable and careful detail the problems concerned with locker plants, packaging materials, nutritive values and vitamin retention, the cooking and serving of frozen foods, and finally a concise treatment of quality control.

An appendix of approximately 70 pages gives the standards and official methods of testing this important class of food materials.

Altogether this work is cyclopedic in scope and represents an enormous amount of work, both original and bibliographic, on the part of the authors. The first three chapters cover in less than 100 pages the principles of

refrigeration and the detailed description of equipment used in different freezing systems. This is presented in a generally clear manner and is especially useful to one who wishes to gain a broad overall picture of modern freezing processes, cold storage, sharp freezing, and especially quick freezing.

The chapter dealing with chemical changes in foods before freezing, while in the chilled state, and after thawing, is particularly well presented. One cannot help expressing admiration for and satisfaction with the factual material given in the chapters on the preparation and adaptability of foods for freezing and the details of the actual freezing process.

As a reference book this volume should be on the shelves of every food technologist, and of every health official or health laboratory director who is concerned with the bacteriological problems of frozen or cold storage foods.

The illustrations are excellent, print easily readable, and paper without annoying gloss. It is a good book and an imposing addition to the literature of food technology. S. C. PRESCOTT

Essentials of Nutrition—By H. C. Sherman and Caroline Sherman Lanford. (2nd ed.) New York: Macmillan, 1943. 442 pp. Price, \$3.50.

This excellent small and up-to-date volume can be recommended unreservedly for the use of public health personnel. The reviewer has frequently recommended it to non-medical friends who ask that they be directed to an informative book on nutrition that will stick to facts and not go all out on the propaganda side. Such a reader would find this book stimulating, though possibly difficult or dull in some places. But he would not emerge from its perusal with any misinformation, and would certainly acquire a profound respect for the rôle of adequate nutrition

in life and health. Dr. Sherman is an advocate of the abundant life in this nutrition question. The standards set up for adequate nutrition might be considered rather luxurious and unattainable by the great majority of the human race. They do represent the ideal, and an attainable one in our nation.

The book is primarily designed for students in nutrition classes, with exercises and suggested readings at the end of each chapter. It follows the usual order of presentation—energy aspects of nutrition, proteins and their amino acids, mineral elements in nutrition, and finally the vitamins. These four aspects of nutrition are preceded by three introductory chapters on the rôle of food in life, and some discussion of metabolism; and the book closes with four special chapters on food and teeth, types of foods, food costs and values, and "Nutrition Policy: Public and Personal."

This last will be of particular interest to public health personnel. Dr. Sherman pleads for the optimum rather than the merely adequate in nutrition and emphasizes the "difference between merely passable health and buoyant health." Both the economic and the educational approaches to this problem are outlined, and some questions of statesmanship discussed.

One of the most valuable features of this volume is the 27 page table at the back on the composition and nutritive value of foods. With its use one can calculate the content of the several nutrients in an individual diet. Practice in the use of this table would be valuable to every member of a health department, all of whom should be informed health educators for better nutrition.

D. F. MILAM

Principles of Medical Statistics—
By A. Bradford Hill (3rd ed.) London: Lancet, 1942. 189 pp. Price, \$2.25.

The third edition of Dr. Hill's book differs in no material respect from the

previous edition. As the author states in the preface to this latest edition "Preoccupation with some of the statistical problems of total war and the national urgency to save paper have made any (such) expansion impossible and I have confined myself to a few verbal alterations."

For the medical man with little or no knowledge of statistics, Dr. Hill's book serves as one of the best introductions to the subject. Even for those who have had some statistical dealings its clear exposition of the logical principles involved in the ordinary statistical procedures deserves a careful reading.

PAUL M. DENSEN

Healthy Babies Are Happy Babies
—By Josephine Hemenway Kenyon, M.D. Boston: Little, Brown, 1942. 343 pp. Price, \$1.50.

This is the third edition of Dr. Kenyon's book by this title and changes have been made which bring it up-to-date in many respects. The newer fish liver oils, vitamin concentrates, sulfa drugs, and non-profit hospital service plans are touched upon. The full discussions of habit training and physical and mental development are, for the most part, in accord with modern concepts. But nutrition is not the author's forte. There is insufficient discussion of the basic principles of nutrition to enable parents to make the best use of the sample menus with their many substitutions.

The organization of the material in chapters relating to age levels from the prenatal period to the age of three years makes it easily accessible. Discussions of the health of the mother are woven into each section.

The chapters on emergencies and diseases of childhood are well done and are timely now that mothers must assume more responsibility for minor illness due to the doctor shortages.

JESSIE M. BIERMAN

Venereal Disease, Diagnosis, Treatment and Laboratory Methods—*Department of Pensions and National Health, 111 Avenue Road, Toronto, Canada.* 98 pp.

This pamphlet was prepared by a committee of thirty-two physicians convened by the Health League of Canada. The names of the members of the committee guarantee the soundness of the contents of the report.

The volume is a handbook for physicians who treat venereal diseases. It gives the essentials of the diagnosis and treatment of these diseases. On account of the limitations of space many details are omitted but if every physician treating syphilis, gonorrhea, chancroid, lymphogranuloma inguinale and granuloma inguinale could be familiar with and apply all that is given in this brochure the treatment of these diseases would be on a very much higher plane than it occupies at the present time.

As might be expected there are some statements made with which many authorities would not agree. There is given a prescription for an astringent urethral irrigation which, in the opinion of many urologists, has no place in the treatment of gonorrhea. It might have been better to omit the details of the intermittent treatment of early syphilis, but in fairness to the committee it should be stated that it does not recommend the intermittent treatment.

The booklet is to be recommended to all physicians who are called upon to treat the venereal disease.

F. L. ROBERTS

A Study of Patients Discharged Alive from Tuberculosis Sanatoria in 1933—*By Jessamine S. Whitney and Mary V. Dempsey. Social Research Series—No. 8. New York: National Tuberculosis Association, 1942.* 58 pp. Single copies free.

This study represents a joint effort

of the National Tuberculosis Association and the Division of Vocational Rehabilitation, U. S. Office of Education. The purpose of the study is "an attempt to answer the question, 'What type of patient who has had sanatorium care is feasible for and will profit most from intensive organized service?'" Seventy-five public sanatoria in sixteen states and the District of Columbia voluntarily coöperated in the undertaking.

Some of the difficulties to be encountered in a problem of this kind are discussed, and one very important section of the report deals with recommendations prepared as the result of experience acquired in this study.

This report will be of value to all persons interested in tuberculosis and especially to those who have the planning and execution of rehabilitation programs for tuberculous individuals. More complete information in this field is very much to be desired and this is a worth while addition to our knowledge in this respect.

H. C. STEWART

Public Health in Bridgeport, Conn.—Report of a Public Health Survey by the Department of Health, Yale University School of Medicine, 1942. 91 pp.

Undertaken under the able leadership of Professor Ira V. Hiscock, this report, in common with other studies made by the Department of Health of the Yale University School of Medicine, is replete with meaningful information concerning the health situation of the community.

The report discusses in some detail the present status, and in some instances the past history, of activities and services in the various phases of public health endeavor: vital statistics, water supply, sewage disposal, refuse collection and disposal, housing, milk control, food, sanitation, control of

communicable diseases, venereal diseases, tuberculosis, maternal and child health, school health, public health nursing, and special problems such as crippled children, hearing and vision, nutrition, mental hygiene, cancer, and heart disease. There are also brief discussions of community health education, organized care of the sick, and the Community Chest and Council of Social Agencies.

Each major section has a summary with pertinent suggestions as to what ought to be done to correct weaknesses. The dominant weakness is the lack of an adequate staff of well trained people.

The report concludes with three pages devoted to "Tentative Suggested Recommendations for a Long-Term Program."

To those interested in the development of public health over a period of years the report sounds a sad note in that it shows clearly how a health organization and program which stood in the front ranks three decades ago has retrogressed and failed to keep pace with the times until now it has reached its lowest ebb. Fortunately such examples are rare. The retrogression in organization and program is spoken of quite frankly but the underlying causes responsible for the failure are not made clear except perhaps there is a hint to the reader as the report calls attention to the weakness of the community health education program.

The report is well worth reading. It would have been easier reading, and just as effective, with fewer statistics. The detailed statistical information might well have been placed in an appendix.

As an experience for students of public health the survey was doubtless of very real value. The written report also constitutes a useful document for teaching. If the report is designed to bestir the people of Bridge-

port to effective action it leaves much to be desired. It lacks forcefulness and proper emphasis. All the suggestions for needed improvements are included, but they do not stand out in bold relief and all too frequently they are offered as suggestions rather than as clear-cut, definite, forceful recommendations.

CARL E. BUCK

Mental Health in College—By Clements C. Fry, M.D., with the collaboration of Edna G. Roston. New York: Commonwealth Fund, 1942. 382 pp. Price, \$2.00.

In this analysis of the records of Yale students with emotional difficulties, the authors present interesting case histories illustrating the various factors entering into the development of emotional problems over a 10 year period. They also explain clearly, and at length, their significance to educators and to those responsible for the early training of students.

Dr. Fry demonstrates and explains how important are such factors as the family, ignorance of sex changes in a maturing youth, scholastic deficiencies, and the social strivings and disappointments of young people, even in a university environment as nearly perfect as that of Yale. Studies are also presented of the special problems developing among students during each of the 4 years of undergraduate work, and of those arising in the graduate schools. The psychiatric cases, though relatively few, are also analyzed.

In order that he may understand the environments in which these difficulties develop, the reader is told a good deal about life at Yale.

Reports on the analyses of case records are often dry and difficult to read. Not so, this book. Though it is long, requires careful reading, and even study, it is well written and contains valuable material.

Those living and working with col-

lege students will find in this book a most sympathetic understanding of their problem cases. To school administrators and to educators in gen-

eral, this study will present a challenge to devote more study to this field of emotions.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

When Johnnie Comes Marching Home—Every man and woman among us should heed this editorial which concludes that although the value of diphtheria prophylaxis is proved beyond doubt, experience in England and Australia with the *gravis* form should convince us that the present state of knowledge concerning the control of diphtheria is not conducive to a state of complacency—a state in which most of us find ourselves, I suspect.

ANON. Grave Diphtheria. J.A.M.A. 122, 3:176 (May 15), 1943.

"Eat These Foods Every Day"—Nutritionists occasionally leave the impression that adequate diets are dependent upon a rigid food pattern. In the army they have found it necessary, and possible, to make a variety of substitutions for the "must" foods.

BERRYMAN, G. H., and HOWE, P. E. Some Nutritional Principles of Mass Feeding. J.A.M.A. 122, 4:212 (May 22), 1943.

Reminder That Vaccinia Works Faster—Antibodies against vaccinia begin to appear at the end of the first week following cutaneous vaccination, and reach a maximum at the close of the 3rd week; in variola the same antibody response occurred 26 to 30 days after infection.

BLATTNER, R. J. Antibody-Response to Cutaneous Inoculation with Vaccinal Virus in Human Subjects, Utilizing the Egg-Protection Technic. J. Immunol. 46, 4:207 (Apr.), 1943.

Toward Intelligent Eating—Food habits, food advertising, food processing, food waste, and a few other factors that interfere with good nutrition are subjected to telling scrutiny.

CARLSON, A. J. Some Obstacles in the Path Towards an Optimum Diet. Science. 97, 2522:385 (Apr. 30), 1943.

Whooping Cough — Killer of Babies—Though whooping cough mortality rates have declined markedly in recent years, it is not likely that prophylactic vaccinations have been widely enough employed to have exerted any great influence upon this decline, and should the mortality rates continue to go down it will be extremely difficult to assess the relative influence of the future extension of this preventive measure.

DAUER, C. C. Reported Whooping Cough Morbidity and Mortality in the United States. Pub. Health Rep. 58, 17:661 (Apr. 23), 1943.

Hodge-Podge Health Education—Among other examples, transcripts of nursing visits record the advice of one nurse to Mrs. A. to nurse the baby on alternate breasts, and of another nurse to Mrs. B. to nurse the baby on both breasts at each feeding. What will Mrs. A. and Mrs. B. think if they compare notes? And who would blame them for their opinions?

DERRYBERRY, M., and BROCKETT, G. S. Preserving Confidence in Health Education. Pub. Health Nurs. 35, 5:244 (May), 1943.

More TB Case Finding—Records of drafted boys deferred because of chest x-ray findings and reported to the state department of health are turned over to local officials for follow-up. Of 3,112 so deferred only 417 had been previously reported. Completed histories of 1,540 not earlier reported, indicated that 78 per cent were affected with TB in some form.

EAKINS, W. T. Tuberculosis in War Time in New Jersey. *Pub. Health News.* 26, 8:225 (Apr.), 1943.

War-Work and TB—Chest examinations of more than 15,000 industrial employees revealed 0.61 per cent with evidence of clinically significant pulmonary tuberculosis: apparently arrested 2.92 per cent. Increased tempo of industrial production with all its social and economic overtones calls for tuberculosis control programs throughout all industries.

EDWARDS, H. R. Tuberculosis in Industry. *Am. J. Med. Sci.* 205, 4:571 (Apr.), 1943.

Rats and Typhus—Rat-flea transmitted typhus cases are reported in southern United States in ever increasing numbers. Rat proofing of buildings and destruction of garbage would do away with excess rat populations and stop the spread of this needlessly endemic disease. A unit of the U. S. Public Health Service is cooperating with state authorities to this end.

ESKEY, C. R. Murine Typhus Fever Control. *Pub. Health Rep.* 58, 16:631 (Apr. 16), 1943.

Mechanism of Protection—Vaccination with influenza virus not only stimulates production of circulating antibodies but increases the capacity of nasal secretions to neutralize virus. If you want to know some of the implications of this finding you must search out this stimulating paper in the magazine noted below.

FRANCIS, T., JR., *et al.* The Effect of Subcutaneous Vaccination with Influenza Virus upon the Virus-Inactivating Capacity of Nasal Secretions. *Am. J. Hyg.* 37, 3:294 (May), 1943.

After the Uncoöperative Patient Departs—Half the tuberculous patients who left three city sanatoria against advice in 1935 were found, 7 years later, to have died. Another third had relapsed but were still hanging on.

This is a public health problem of the first magnitude, wisely concludes the writer.

GUEST, K. R. Follow-up of the Known Tuberculous Patient. *Am. Rev. Tuberc.* 47, 3:325 (Mar.), 1943.

Liver for Blood Donors—Of interest to all blood donors—as who of us under 60 isn't—is this discussion which concludes that good nutrition favors rapid blood regeneration. Among the proteins rich in iron, liver, kidney, and oysters seem to be featured.

McKIBBIN, J. M., and STARE, F. J. Nutrition in Blood Regeneration (and) TURNER, D. F. Dietary Recommendations for Blood Donors. *J. Am. Diet. Assoc.* 19, 5:331 (May), 1943.

TB in the Publicly Assisted—Among 5,000 unemployed adults examined and reexamined for tuberculosis, only one of the originally negative cases was later found tuberculous, and among the healed cases only one was found to be reactivated 12 months later. Annual reexaminations of these people would seem not to be economically justified.

MILLER, R. E., and HENDERSON, B. The Epidemiology of Tuberculosis in a Low Income Group. *Am. Rev. Tuberc.* 47, 3:334 (Mar.), 1943.

Remember This One Next Winter—Oral administration of heat-killed "cold" vaccines had no influence on the incidence or severity of common colds when tried upon volunteers from the Visiting Nurse Service of New York City.

SIEGEL, M., *et al.* A Study of the Value of a Mixed Bacterial "Oral Cold Vaccine." *Am. J. Med. Sci.* 205, 5:687 (May), 1943.

Syphilis Discovery Rates—Substantial reductions in congenital syphilis are reported from Baltimore. Despite better case finding facilities, no new cases were unearthed among white children under 5, and only 12

cases among Negroes during the last 3 years. Among white adults a significant decline in annual discovery rates occurred, but there was no convincing evidence of the same trend among the colored.

TURNER, T. B., *et al.* Studies on Syphilis in the Eastern Health District of Baltimore City. *Am. J. Hyg.* 37, 3:273 (May), 1943.

"Medical Treatment for Every Briton in Whatever Form He Requires It"—According to the Beveridge

report no satisfactory social security scheme can be devised except on the following assumptions: (a) school children's allowances; (b) health and rehabilitation services for everyone; (c) maintenance of employment. What assumption (b) means in terms of British health and medical services is discussed in detail.

UNDERWOOD, E. A. The Beveridge Report and the Health Services. *Pub. Health.* 56, 8:89 (May), 1943.

 Martin H. Knutsen, M.S., State College, Pa., Elected Member 1919, Unaffiliated

CHANGES IN THE APPRAISAL FORM FOR COMMUNITY HEALTH WORK

Dr. Henry F. Vaughan, Chairman of the Committee on Administrative Practice, has announced recent decisions of the Committee on Administrative Practice with respect to the appraisal of local health work which will be of interest to health officers over the country.

Up until recently there have been two distinct forms, one the *Appraisal Form for Local Health Work* (1938 edition), and the other the *Evaluation Schedule*, used in connection with the National Health Honor Roll, and, prior to that,

in the Interchamber Health Conservation Contest. As these two forms called for different types of information and were set up on different principles, there has been confusion over their uses. In order to avoid this confusion, the Committee on Administrative Practice has decided to limit appraisal practices to one form.

The *Evaluation Schedule* has been selected as the surviving form. The *Appraisal Form for Local Health Work* has, therefore, been discontinued and

will not be revised or reprinted. The few remaining copies on hand will be sent out to those who request them.

The *Evaluation Schedule* will be revised to some extent and reissued this fall. It will be recognized hereafter as the official form for appraisal purposes. It will be used both in connection with the National Health Honor Roll and for other purposes as may be needed.

The Committee on Administrative Practice has also approved the preparation of a *Guide to the Evaluation Schedule* which it is expected will be published in the fall. One further decision was to approve the issuance of a booklet to be known as "Health Practice Indices." This will consist of a series of charts showing the range of units of practice for cities and counties which have submitted schedules for the years 1941 and 1942. It is believed that this pamphlet will serve a most useful reference purpose to health officers as it will depict practices over the country as represented by those communities which have participated in

the National Health Honor Roll in the last two years.

The preliminary revision of the *Evaluation Schedule*, the preparation of the *Guide*, and the compilation of the *Health Practice Indices* are now under way in the hands of the subcommittee on Manual and Appraisal of Local Health Work.

The material will be submitted for approval at a projected meeting of the subcommittee in the late summer, and it is hoped that all material will be available in published form before the end of the year.

CLOSING DATE FOR SUBMITTING

FELLOWSHIP APPLICATIONS

Members who may be interested in applying for Fellowship in the A.P.H.A. are hereby advised that Fellowship applications should be received by the Central Office not later than August 1, to insure consideration at the Wartime Public Health Conference and 72nd Annual Business Meeting to be held in New York October 12 to 14.

WORKSHOP ON ADJUSTMENTS DURING WARTIME OF SCHOOL HEALTH PERSONNEL

The most pressing school health problem today is the adjustment of personnel to meet the war emergency. The School Health Section, in coöperation with the Food and Nutrition Section and the American School Health Association, will conduct a Workshop on this subject in connection with the Wartime Conference in New York City, October 12-14. The Workshop will be

divided into three groups for discussion of problems in (a) rural areas, (b) medium size communities, and (c) large cities.

Registration for these working sessions is limited to 30 for each of the three groups. Complete details may be obtained from Dr. George M. Wheatley, Secretary, School Health Section; 1 Madison Avenue, New York, N. Y.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of

Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Merit System for Personnel Administration, Delaware, is accepting applications for position of Deputy State Health Officer in Delaware State Board of Health. Salary range \$3,600 to \$4,200. Applications accepted until further notice. Those interested should communicate with Merit System Supervisor, P. O. Box 1911, Wilmington, Delaware, or State Board of Health, Dover, Del.

Sanitarian wanted: Starting salary \$1,800 per year with travel allowance of \$50 per month. Man must have own car. Bachelor's degree followed by at least one year's course or its equivalent in subjects necessary for one entering the public health field, or an engineering degree plus one year's experience in sanitary or public health engineering required. A course in public health training may be considered as an equivalent for a part of the experience requirement. Apply Dist. Dept. of Health No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Two physicians, immediate appointment, full-time venereal disease clinician, conduct several small clinics rotating schedule. Experience preferred. Salary \$3,600 plus actual expense not to exceed \$1,200. Write State Health Department, Santa Fe, New Mexico.

The Board of Health, Territory of Hawaii, announces applications will be received for positions as Medical Technician in their public health laboratories. The positions: Civil Service Classifications, SP-5, salary range \$154.17 to \$192.92 per month; SP-6, \$172.50 to

\$217.50 per month, subject to retirement deductions under Hawaiian Civil Service System, plus graded bonus for the period of time such bonus remains in effect for Territorial Government employees.

Interested persons may make written application to Board of Health, Territory of Hawaii, P. O. Box 3378, Honolulu, T. H.

Notice of an expected vacancy for an Industrial Hygiene Engineer in the Los Angeles County Health Department has been received. Those interested should communicate with Dr. H. O. Swartout, Acting County Health Officer, Los Angeles, Calif.

Announcement is made of the following examinations to be held by the State Personnel Board, Seattle, Wash., for positions in the State Department of Health and County Health Departments:

For further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

SERVICES FOR THE CHILDREN OF WORKING MOTHERS

Further extension of the assistance offered states and localities in the development of services for the children of working mothers has been announced by Charles P. Taft, Director of Community War Services, Federal Security Agency.

Thirty-three state departments of education and 28 state departments of welfare in 38 states, the District of Columbia, and Hawaii have received grants from an allocation from the President's Emergency Fund administered by Mr. Taft's office. The states have been notified that personnel may continue to be paid from this fund through the current fiscal year.

Grants are made by the Federal Security Agency on the basis of state plans approved and recommended by the Children's Bureau of the U. S. Department of Labor or the U. S. Office of Education.

Field representatives of the Office of Education and the Children's Bureau work with state departments of education and welfare in organizing and planning state programs, and make recommendations to the Federal Security Agency's Office of Community War Services for grants to help carry out these plans.

Personnel employed through these grants are engaged in a variety of activities to help set up a wartime child care program. Many of them are coördinators of state or local programs working with Child Care Committees of the Defense Councils to expand, extend, and integrate services of the public and private agencies in the state or locality. Others, specialists in the fields of child welfare, nursery school education, and

extended school programs, have given local welfare and education authorities technical guidance in the development, administration, and supervision of specific types of services for the children of working mothers.

AMERICAN-SOVIET MEDICAL SOCIETY FOUNDED

To meet an increasing demand for information about the results and achievements of Soviet medicine, the formation of the American-Soviet Medical Society is announced.

The society will keep physicians of America and members of the allied professions informed through meetings, the publication of a journal, and the establishment of a library of information. American medical books and periodicals will be sent to the Soviet Union to advise the Russians of scientific developments in this country and to stimulate closer coöperation between the medical corps of the two countries. After the war, as soon as conditions permit, the society hopes to promote the exchange of students and scientists and to sponsor study tours in the two countries.

The president of the society is Dr. Walter B. Cannon, Professor Emeritus of Physiology at Harvard University, member of the National Academy of Sciences of the United States and of the Academy of Sciences of the U.S.S.R.

Dr. Henry E. Sigerist, Director of the Institute of the History of Medicine, Johns Hopkins University, is the editor of the journal which will be known as the "American Review of Soviet Medicine."

The temporary offices of the society are at 130 West 46th Street, New York, N. Y.

FEDERAL EMPLOYEE HEALTH PROGRAM

"The Health Program of the United States Bureau of the Census," by Leon Schwartz, M.D., Medical Officer, is a report on a health program for the employees of the Bureau of the Census working in the new office building at Suitland, Md. Dr. Schwartz is responsible for the organization and conduct of the program which embraces preventive, diagnostic, and therapeutic services. A good deal of progress can be recorded since he took charge on September 1, 1942, and there are ambitious plans ahead. Medical forms and records are reproduced in the report, and an organization chart and a floor plan of the medical unit. Copies of the report may be obtained from Dr. Schwartz.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

The Northern California Public Health Association announces that the following new officers were elected at the recent Annual Meeting of this society:

President—William A. Powell, M.D., Martinez
President-elect—Dwight M. Bissell, M.D., San Jose
Vice-President—Walter S. Mangold, Berkeley
Treasurer—Helen S. Hartley, R.N., Stockton
Secretary—Ann W. Haynes, San Francisco
Representative on A.P.H.A. Governing Council—John D. Fuller, M.D., Santa Cruz
Representative on Regional Board of A.P.H.A. Western Branch—Malcolm H. Merrill, M.D., Berkeley

A CALIFORNIA SCHOOL OF PUBLIC HEALTH

Governor Earl D. Warren of California has signed a bill, previously passed unanimously by the Legislature, authorizing the Board of Regents of the University of California to establish a school of public health for the graduate training of all classes of public health personnel and appropriating modest funds therefor. It is stipulated that the

funds must be used during the current biennium. It is planned to use existing facilities on all campuses of the University of California which may be useful in this training. Last year Dr. Walter H. Brown, formerly Professor of Hygiene at Stanford University, was released to the University of California at Berkeley to assume chairmanship of the Department of Hygiene and to prepare the way for a school of public health.

FLORIDA PUBLIC HEALTH ASSOCIATION

New Officers of the Florida Public Health Association for the current year are as follows:

President—Leland H. Dame, M.D., Sanford
1st Vice-President—J. B. Miller, Jacksonville
2nd Vice-President—W. W. Rogers, M.D., Jacksonville
Secretary-Treasurer—Edward M. L'Engle, M.D., Jacksonville

DR. ELVEHJEM RECEIVES WILLARD GIBBS MEDAL

The Willard Gibbs Medal, ranking honor in American chemistry, has been presented by the Chicago Section of the American Chemical Society to Conrad A. Elvehjem, Ph.D., Professor of Biochemistry at the University of Wisconsin. The award recognized Dr. Elvehjem's work in the study of "trace elements" in nutrition and on tissue respiration as applied to the study of vitamin function.

NURSING IN WAR MANPOWER COMMISSION

Alma C. Haupt, R.N., has been designated Chief of the Nursing Supply and Distribution Unit established in the Placement Bureau of the War Manpower Commission recently. The new unit is designed to effect an equitable distribution of graduate nurses for military, governmental, and essential civilian needs. State and local Councils for War Service will be utilized for the

operation of the unit. Quotas will be set up on national and state bases for the guidance of nurses in accepting service in military, governmental, and essential civilian activities. Katherine Tucker, R.N., Director of the Department of Nursing Education, University of Pennsylvania, has been appointed Chairman of an Advisory Committee to the Nursing Supply and Distribution Unit.

CHRONIC ILLNESS IN NEW YORK CITY

The Welfare Council of New York City offers to readers of the JOURNAL a limited number of copies of *Chronic Illness in New York City*, by Mary C. Jarrett, a study in two volumes made by the Council's Research Bureau. The only charge is for wrapping and mailing, amounting to about 20¢. Requests for copies should be addressed to: Edgar J. Sherman, Director of Finance, Welfare Council of New York City, 44 East 23rd Street, New York, N. Y.

HANDBOOK ON RHEUMATIC FEVER

"Rheumatic Fever in Children—Its Recognition and Management" is a brief clinical handbook written for the practising physician which, perhaps for the first time, makes available under one cover the modern concept of the disease in its various aspects. It describes in concise and authoritative style, the early diagnosis and treatment of rheumatic fever and the methods of managing the disease and recognizing its cardiac involvements. This handbook has been developed by the Metropolitan Life Insurance Company as a part of the insurance company's current educational drive against rheumatic fever. It was prepared in consultation with a group of distinguished clinicians and the following organizations: The American Heart Association, The American Academy of Pediatrics, The Children's Bureau of the

U. S. Department of Labor, The U. S. Public Health Service.

Single copies of the handbook are being made available to physicians chiefly through the Metropolitan's 16,000 field representatives. Physicians who have not secured a copy may write to Dr. George M. Wheatley, Assistant Medical Director, Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y.

PROPOSED BUREAU OF VITAL RECORDS

The principal provisions of Senate Bill 1096—"To Establish a Bureau of Vital Records in the U. S. Public Health Service and for other Purposes"—

The Bill provides:

For the transfer of the vital statistics activities of the Bureau of the Census to the U. S. Public Health Service. The head of the proposed new bureau is to be an assistant surgeon general, and his duties will be to promote improvement of registration of vital statistics procedures in the states, and to coördinate practices with regard to the records of births, deaths, marriages, and divorces. It is proposed that the records and personnel of the Bureau of Vital Statistics be transferred from the Bureau of the Census to the U. S. Public Health Service.

For the purpose of assisting states and their political subdivisions in establishing and maintaining adequate vital services, including training of personnel, it is proposed that there be appropriated the sum not to exceed \$2,000,000 for a year. This sum is to be allocated in much the same way as Title VI Social Security Funds are at present distributed.

MATERNITY CARE

As of May 20, with plans of other states expected to be acted on in a few days, twenty-three state health agencies were authorized to provide maternity care for wives of men in the four lowest

pay grades of the armed forces, and medical hospital and nursing care for their babies, both without cost to the family, according to the Children's Bureau.

States whose programs have been submitted and approved are: Arizona, Arkansas, Connecticut, Delaware, Illinois, Indiana, Kentucky, Maine, Maryland, Michigan, Mississippi, Nevada, New Jersey, New Mexico, North Carolina, Oklahoma, Rhode Island, South Carolina, Utah, Vermont, West Virginia, Wisconsin, and Wyoming.

Under approved states plans, wives of these service men may receive complete medical care during pregnancy, childbirth, and 6 weeks after. At childbirth, whether the wife stays at home or goes to a hospital, she and her baby may have medical and nursing care. Medical care is also provided for the baby throughout his first year of life. All that the wife needs to do to apply is to fill out a simple form which she can get from the state health department.

FIELD TRAINING IN HEALTH EDUCATION AT THE CLEVELAND HEALTH MUSEUM

During the month of August, 27 students in health education from the University of North Carolina will work as Museum interns to receive a course of instruction, do laboratory work, and gain field experience in the methods of health education, especially in health exhibits. Among those students are the 17 individuals who were awarded fellowships by the U. S. Public Health Service, from a grant made available by the W. K. Kellogg Foundation.

The 4 week course at Cleveland Health Museum is part of 3 months' academic training in order to obtain a degree of Master of Science in Public Health. The course will be conducted by Bruno Gebhard, M.D., Director of the Cleveland Health Museum and Associate in Health Education, Western

Reserve University School of Medicine.

Besides instruction in the principles and methods of visual health education the students will gain practical experience in three work units; on ideas, facts, figures, and manuscripts; on designing, constructing, and budgeting of exhibits; and on placement, publicity, visitors' reaction, and follow up.

The Museum's facilities including the workshops, the loan service, traveling exhibits, the film library, and the Museum's own exhibits will be used for this training.

SOME SENATORS DO ANSWER THEIR MAIL!

Among the constituents of all 96 United States Senators, there are many public health workers, we have reason to know, who have been perturbed by the implications of Senate Bill 575. This is the bill introduced by Senator McKellar which would make appointments to all positions in the Executive Branch of the Government carrying a salary of more than \$4,500 a year subject to the approval of the Senate. Its status on May 26, as this is written, is that it is on the calendar.

The Association asked all Senators this question by telegraph on May 11:

What shall I reply to a promising young public health man who believes that passage of Senate Bill 575 will deprive him of all career opportunity in public service as a policy making officer? The American Public Health Association reflects opinion of public health profession that this bill will seriously undermine growing confidence in the Civil Service.

Senators O'Daniel (Texas), Hawkes (New Jersey), and Mead (New York) replied by wire the same day. Each will "give measure consideration." Senator Hawkes added "regards" and the information that he has been studying the bill carefully.

Senator Truman (Missouri) personally acknowledged the wire the day it was received. He "will be glad to

give these views consideration in the event that the bill should come up for vote."

So did Senator McKellar (Tennessee). His twenty word letter said merely that he introduced the bill only after the most careful thought and consideration.

Senator Van Nuys (Indiana) answered via Clerk J. F. Mattice on May 12. He suggested the following reply to the promising young man:

That the bill is not intended to deprive him of all career opportunity in public service and will not operate to do such thing; that the same opportunity will exist as does in the Army and Navy and Coast Guard services, all of whose officers are and for a long time have been confirmed by the Senate after nomination by the President. Young men set about on a Career in the Army or Navy, or in the diplomatic service, and are not deprived of all career opportunity because they are required to be appointed by the President by and with the advice and consent of the Senate. The system as to those career men works very well and no appreciable amount of time of the Senate is taken up in making confirmations. Thirdly, such method of appointment of policy making, army, navy and diplomatic representatives, is the constitutional way—in accordance with the provisions of the Constitution of the United States. The present Bill is aimed at the thousands of persons who have been "blanketed into civil service status" since Pearl Harbor and placed upon positions where they issue orders, regulations, etc., having the effect of law (though not enacted by Congress), which affect the lives and welfare of the citizens of the United States. The public holds Congress responsible for the things of that sort about which they complain, though Congress has nothing to say about their selection.

Senator Pepper (Florida), in a personal acknowledgment dated May 12 was "inclined to oppose" the bill, although he had not made a detailed study of it.

Senator Burton (Ohio) sent an undated, mimeographed reply (received on May 14) which was necessary, it was explained, because of the heavy mail on the bill. He agrees with "the

need for preserving the merit system and the Civil Service." He does not believe it necessary to follow Senator McKellar's proposal. He is "opposed to the bill as it was originally introduced" but it "deserves consideration" in its new form as amended by the Committee. If, however, the new form "still weakens substantially the effectiveness of our merit system, as it apparently does," he will "continue to be opposed to it." Senator Burton added a handwritten note to his thoughtfully prepared form letter—"I believe that your young friend need not worry about his career on merit if he will continue to concentrate on the high degree of public service that is the proper basis of advancement."

Senator Capper began his letter dated May 17 with an apology for his delay in replying and continued:

The bill does not make a special provision for health officers, who would be affected in precisely the same way as all the other better-paid executive employees of the federal government. There seems to be considerable opposition to the McKellar bill, as well as the Hatch and O'Mahoney substitutes, which would require that government officials drawing more than \$4,500 be confirmed by the Senate. Current information is pretty much to the effect that there may not be any action at all at this Session. I am strong for Civil Service and the merit system. Senator McKellar's bill is now on the Senate Calendar with a favorable report from the Senate Judiciary Committee. You may be sure I will go into the subject thoroughly when it comes up in the Senate for consideration and action. I certainly do not want to do anything that will destroy the principles involved in the Civil Service Program.

And that is how the score stands for our side: nine hits, three runs, and eighty-five errors. Perhaps we should make that four hits, and one less error, because one of our spies sends us a letter from Senator Wagner (New York) who believes "the bill, in operation, would seriously impair the merit system." Yes, some Senators do answer their mail!

PRACTICAL ACTION BY STATE AND LOCAL HEALTH DEPARTMENTS TO MEET
THE PERSONNEL SHORTAGE

The A.P.H.A. Committee on Professional Education at its meeting on June 11 reviewed the present personnel shortages with the background of experience of its own members, representing a wide coverage in the nation, and with the help of consultants invited for the purpose of completing the picture.

It is apparent that acute shortages are now general in the supply of public health engineers, of doctors with administrative training and experience, and of public health nurses. Other shortages are rapidly becoming more serious due to the absence of the usual recruits from the universities.

It is also apparent that these shortages have reduced essential services from health agencies of all kinds, even in those areas of acute need where more service is now required than in peacetime. There can be no question but that these reductions have already an unfavorable effect on the public health. Members of the committee reported having seen sanitary sewage running in open ditches through heavily populated streets, and it is common knowledge that maternity care in some areas is small in amount and of indifferent quality. It is also common knowledge that attacks of gastroenteritis are becoming common among all travelers who must depend on the overburdened food handling facilities and there is reason to believe that the usual barriers to the spread of such infections are seriously lowered. Supervision of water and sewage treatment plants and of milk pasteurizing facilities has been notably weakened by the withdrawal of those trained and experienced in this work. The hygiene of critical industries is being neglected in some places at a time when the output of factories will determine the outcome of the war.

The attention of the committee was called to the fact that a considerable number of the states have at their disposal more funds than they are using. The real problem lies in finding competent persons who can render basic public health services, upholding standards which have been proved so necessary to the protection of life and health. In some instances it was said that the high qualifications set up in peacetime now stand in the way of bringing onto staffs persons who can render acceptable service, although they cannot meet the standards set previously for career service.

Inasmuch as the Committee on Professional Education of the American Public Health Association has for more than ten years spent its full efforts in lifting levels of professional service in health agencies, it seems appropriate for the committee to face quite realistically the situation which the emergency has brought and to take the measure of the man power shortage as it affects public health.

The committee was reminded that the Association has officially declared at the last meeting that professional qualifications should be upheld for those persons seeking permanent status but that, when the emergency demands that inadequately trained personnel be employed, such persons should be placed on temporary appointment and in special grades below those which the position would normally rate. The Association has further recommended that every effort be made to continue the professional training of all types of persons, utilizing to the fullest extent the funds which are available from all sources. There is no evident lack of funds at the present time, as indicated by the unused balances of federal appropriations which are being re-

turned at the fiscal year end, and the committee reaffirms the necessity of adapting the training program of each agency to the needs of the situation. It is the understanding of the committee that the U. S. Public Health Service and the Children's Bureau have already made provision for a special class of "war service" personnel in acceptable budgets. There is evidence that the schools of public health and other training institutions will be most coöperative. It is a perilous state indeed when those responsible for the health of some of our large population units neglect the opportunity of using available funds for the preparation of any who can help in this emergency.

The availability of women for work ordinarily done by men and of those of older years has been well established. Sanitation services and other basic protections of the public health must not be allowed to suffer at a time like this. The committee recommends that all state health officers take the steps necessary to get under training those whose services are so urgently required. Some of these persons can and should be sent now for formal academic courses of longer or shorter duration, according to the situation in each state. Some persons can and should be employed now, even if their qualifications are incomplete according to standards previously declared. There is good precedent for placing these persons in war service positions where they can contribute most, and then seeing that they have either academic or in-service training to the practical limit available.

The committee is confident that the career standards to which it is already so fully committed may be protected safely for the future only if such urgent steps as these are promptly taken by appointing officers. We believe that the initiative for such steps is a proper responsibility of state and local health officers who are facing present and

prospective staff shortages. In presenting this challenge to the public health profession the committee directs its own staff to lend all possible aid and assistance to accomplish these ends.

SAN FRANCISCO OPENS SOCIAL

HYGIENE WOMEN'S COURT

Dr. J. C. Geiger, Director of Public Health, announced the opening of the San Francisco City Separate Women's Court, located in the Health Center Building, San Francisco. The Separate Women's Court is established to meet the problem of the professional prostitute, streetwalker, and other sexually promiscuous women who are arrested by the Police Department.

Prior to the opening of the Separate Women's Court these women were housed in the women's section of the San Francisco City Prison. During their confinement first offenders were placed with habitues and frequently with other criminals thus affording an excellent opportunity for promoting the maladjustment of the first offender.

The objectives in the Separate Women's Court are to render an entirely individualized case study plan. Every effort is made to provide means for adequate referral of first offenders who present a potentiality of reëducation and readjustment.

The medical coördinator of the Separate Women's Court is the Chief of the Division of Venereal Diseases, Dr. Richard A. Koch. The personnel of the Separate Women's Court consists of a judge, a medical coördinator, a deputy district attorney, a woman physician, a registered nurse, three social workers, four police matrons, one court reporter, one court clerk, a bailiff, and two general clerk stenographers.

WAR MANPOWER COMMISSION CREATES UNIT ON NURSING SUPPLY

Paul V. McNutt, the Chairman of the War Manpower Commission, has an-

nounced the creation of a division on nursing supply and distribution similar to the Procurement and Assignment Service for medical and engineering personnel. Alma Haupt, R.N., of Washington, has been appointed chief of the unit, with Miss Louise Baker of San Francisco as associate chief. Katherine Tucker, R.N., of Philadelphia has been appointed Chairman of the Unit's Advisory Committee. Liaison members of the Unit include the National Nursing Council for War Services, American Red Cross, the Army, Navy, Veterans Administration, and Public Health Service, the Children's Bureau, the Office of Indian Affairs, the Office of Civilian Defense and the Civil Service Commission.

"YOUR HEALTH" RADIO PROGRAM

Carl A. Wilsbach, M.D., Commissioner of Health of Cincinnati, began a new series of weekly radio broadcasts over Station WLW on June 19. The program is entitled "Your Health," is broadcast at 9:45 A.M., E.W.T., on Saturdays, and is sponsored by the Academy of Medicine, the Public Health Federation and the Cincinnati Board of Health. It utilizes Dr. Wilsbach as narrator, interspersed with dramatic sequences.

Central States

CLYDE D. BLAKE, M.D., of Hays, Kans., Past President of the Kansas Medical Society, has been appointed a member of the Kansas State Board of Health.

GILBERT G. COTTAM, M.D., of Sioux Falls, S. D., has been appointed Superintendent of the South Dakota State Board of Health, to succeed the late J. F. D. Cook, M.D. W. R. GIEDT, M.D., Assistant State Health Officer and until Dr. Cottam's ap-

pointment, Acting Superintendent of the Board of Health, has resigned to accept a position as Epidemiologist for the State Health Department of Washington.

I. R. VAUGHN will head the Division of Public Health Education, which has recently been established by the South Dakota Health Department. Mr. Vaughn is also Assistant Director of the Division of Vital Statistics.

Eastern States

VLADO A. GETTING, M.D.,* since 1942 Commissioner of Health of Worcester, Mass., has been appointed Commissioner of Public Health of Massachusetts to succeed PAUL J. JAKMAUHI, M.D.,† of Boston.

ROGER E. HEERING, Passed Assistant Surgeon, U. S. Public Health Service, has been lent to the State of Ohio for service as Venereal Disease Control Officer. Dr. Heering came from District No. 1, U.S.P.H.S., with headquarters in New York, where he had been Venereal Disease Consultant for 10 states included in the district. Dr. Heering had been lent to Ohio during the period 1939-1940 as Venereal Disease Control Officer in the Cincinnati area.

JOSEPH LACHMAN, M.D., formerly of Chester, Pa., U. S. Public Health Service, was recently appointed in charge of the Pulaski and McCreary County Health Departments.

PROFESSOR SAMUEL CATE PRESCOTT,* of Brookline, Mass., Emeritus Dean, School of Science, Massachusetts Institute of Technology, Cambridge, Mass., has been awarded the Nicholas Appert Medal of the Chicago Section, Institute of Food Technologists. Eligibility for the award, established in 1941, is based on preëminence in the field of food technology and on contributions to the progressive development of food manufacture and processing.

* Fellow A.P.H.A.

† Member A.P.H.A.

WILLIAM A. SAWYER, M.D.,* since 1919 Medical Director of Eastman Kodak Company, Rochester, N. Y., has received the 1943 W. S. Knudsen Award of the American Association of Industrial Physicians and Surgeons, for "outstanding work in control of tuberculosis, constructive contributions to a practical program of nutrition in industry, and setting up a program of rehabilitation for handicapped workers in industry."

CHARLES F. WILINSKY, M.D.,* Executive Director and Superintendent of the Beth Israel Hospital, Boston, Mass., on April 12 was awarded the annual medal of the Boston City Club for distinguished civic service. Dr. Wilinsky is Chief Medical Officer of the Boston Public Safety Committee and his selection for the medal was "the outcome of his work in organizing the medical section of the city's civilian defense effort, and for his work during the Coconut Grove disaster." The gold medal is presented each year to the civilian adjudged by the club to have rendered the most outstanding civic service to Greater Boston.

SAVEL ZIMAND,* an administrative assistant in the New York City Health Department for 9 years, has been appointed Acting Director of the Bureau of Health Education. He succeeds CHARLES F. BOLDUAN, M.D.,* first director of the Bureau, who has reached the retirement age.

Southern States

ANTHONY J. BOROWSKI, DR.P.H.,† until recently Chief of the Health Section of the Federal Works Agency, Works Progress Administration, Washington, D. C., has been appointed Chief Clerk and Statistician of the Division of Records and Statistics of the Richmond Department of Public Health.

JOHN S. CHAMBLEE, M.D.,† of Wind-

sor, N. C., Health Officer of Bertie and Chowan Counties, has been appointed Health Officer in Nash County, succeeding THOMAS O. COPPEDGE, M.D.,† of Nashville, resigned.

LELAND H. DAME, M.D.,† Director of the Seminole County Health Unit, Sanford, Fla., was elected President of the Florida Public Health Association at the recent annual meeting in Jacksonville.

DR. W. HARRY FEINSTONE,† formerly associated with Johns Hopkins University, Baltimore, Md., has been appointed as Director of Biological Research by the Pyridium Corporation Yonkers, N. Y.

DOUGLAS H. FRYER, M.D., D.P.H.,† Director of the Rockingham County Department of Health, Spray, N. C., has accepted an appointment as director of the combined county and city health departments at Bay City, Mich.

MAJOR HAROLD B. GOTAAS,† Chief Engineer, Division of Health and Sanitation, Coördinator of Inter-American Affairs, has returned from South America, where he was working on the health and sanitation projects in the different countries.

CHESTER A. HICKS, M.D., DR.P.H.,† Surgeon Reserve, U. S. Public Health Service, was appointed Director of Public Health of the City of New Rochelle, N. Y., on May 1, 1943. Up to this time Dr. Hicks served as Director of Health of the Carter Unicoi-Johnson Health District, Elizabethtown, Tenn.

CHARLES N. LEACH, M.D., C.P.H.,* of Montgomery, Ala., was in Manila, Philippine Islands, at the time of the Japanese invasion and has been interned as a prisoner of war since that time.

* Fellow A.P.H.A.

† Member A.P.H.A.

THEODORE R. SIROP, M.D.,† assumes his duties as Health Officer of Garrett County, Maryland, as of July 1, holding at the same time the appointment of Deputy State Health Officer in that county, which is also known as the First Sanitary District under the Maryland State Department of Health.

BRIGADIER GENERAL JAMES STEVENS SIMMONS,† A.U.S., Director of the Preventive Medicine Division of the Office of The Surgeon General, U. S. Army, Washington, D. C., has been appointed Lecturer in Public Health on the Staff of the School of Medicine at Yale University, New Haven, Conn.

Western States

DONALD J. BOURG, M.D.,† of The Dalles, Ore., recently Health Officer of Wasco and Sherman Counties, has been named Health Officer in Benton and Polk Counties, with offices in Corvallis.

CLAUDE C. CHICK, M.D., has been named Health Officer of Hood River, Ore.

EDWARD E. DART, M.D.,† formerly Director of Industrial Hygiene in the Department of Health of the City of Los Angeles, Calif., has resigned to accept a position with the Chrysler Corporation in Chicago, Ill. YALE ROSENFELD, Assistant Sanitary Engineer, U. S. Public Health Service (R), has been appointed Acting Director of the Division of Industrial Hygiene in Los Angeles.

WILLIAM E. STEELE, M.D., of Olympia, Wash., has resigned as Chief Medical Adviser to the State Department of Labor and Industries, to engage in private practice in Seattle. Dr. Steele, who held the State position for 7 years, will be named Con-

sultant to the Department in the Seattle area.

HAROLD B. STOUT, M.D., of Brewster, Wash., has been named Health Officer of Pateros.

RAGNAR T. WESTMAN, M.D., DR.P.H.,* Surgeon (R) in the U. S. Public Health Service, on April 29 was appointed Acting Commissioner of Health of Seattle, Wash., succeeding FRANK M. CARROLL, M.D.,† retired.

Canada

AIME COUSINEAU, C.E.,* City Sanitary Engineer, Health Department, Montreal, Canada, is now Director of the City Planning Division. He retains his post as City Sanitary Engineer of the Health Department.

ANTOINE B. VALOIS, M.D., M.P.H.,† has been appointed demographer and Superintendent of the Vital Statistics Division of the Montreal Health Department, P. Q., Canada. He is a graduate of the University of Montreal and Johns Hopkins School of Hygiene and Public Health. He succeeds EUGENE GAGNON, M.D., deceased.

Mexico

DR. VICTOR FERNANDEZ MANERO,† Chief of the Federal Department of Health in Mexico, Mexico City, was recently presented with the diploma and the gold medal of a fellow honoris causa of the International College of Surgeons as a token of national appreciation for his work on public health in Mexico.

Deaths

WARREN F. DRAPER, JR., M.D.,* of Paris, Tex., Health Officer of the Paris-Lamarr Health Unit, died in May.

PROFESSOR MARTIN H. KNUTSEN,† a member of the Association since 1919, died on February 6 after a

The National Board of Health* 1879-1883

W. G. SMILLIE, M.D., F.A.P.H.A.

*Department of Public Health and Preventive Medicine, Cornell Medical
College, New York, N. Y.*

VERY few people in the United States, even among that group most actively engaged in national public health affairs, realize that the United States once had a National Board of Health.

It is a dramatic story, and, like all dramas, has its heroes, struggling against overwhelming odds; its villain, who possesses the intelligence and aptitudes that all villains are supposed to exhibit; its comedy; its periods of calm which usually preceded another stormy outburst; its climax, anti-climax, and finale.

The idea of unified, correlated national health services had been germinating slowly since the epidemic of yellow fever in 1793. Three National Sanitary Conventions had been held from 1857 to 1860, and the question of a nation-wide quarantine service was discussed at these meetings. At the first meeting of the American Public Health Association in 1872, Dr. C. C.

Cox, Health Officer of Washington, D. C., gave an excellent discourse on the necessity for a national health organization and outlined its functions and a suitable organization. State Boards of Health were being organized in rapid succession. In 1874 the National Association of State Health Commissioners was formed, and the obvious need for a central federal health agency became more and more apparent.

A meeting attended by representatives of many state and city health departments was held in Washington in 1875 to discuss plans for a federal health organization, but this convention met with little success. The three existing national government departments that already possessed medical officers—namely, the Army, the Navy, and the Marine Hospital Service—flew into a jealous dispute as to which should be most prominent in the new organization; and the meeting closed in dissension. Dorman B. Eaton, the distinguished lawyer who had drafted the pioneer Metropolitan Board of Health

* This article is a chapter of a book in preparation upon The History of Public Health in the United States.

Act of New York in 1867, and also had drawn the act for the New York State Board of Health, was asked to prepare a draft of a bill which would create a National Board of Health. He did so, placing the medical departments of the Army, Navy, and Marine Hospital Service on the same footing. This proved fatal. Both the Army and the Marine Hospital Service rejected the bill and each at once endeavored to secure legislation from Congress which would make its service more prominent in national sanitary work.

The yellow fever epidemic of 1878 precipitated the issue. This devastating outbreak swept up the Mississippi Valley from New Orleans, causing great loss of life and paralyzing industry. The Valley states realized that the invasion came to them from the river, and blamed the Louisiana authorities for lax sanitary administration. They felt that their only hope against future disaster lay in a coördinated health service under national auspices.

In April, 1878, Dr. J. M. Woodworth of the Marine Hospital Service succeeded in getting a bill through Congress which conferred quarantining powers on his department, but he was given no appropriation to carry out the objects of his bill.

When Congress convened in 1879, the sentiment of the public was unmistakable. There must be no repetition of the disaster of 1878. The Army and the Marine Hospital Service both sponsored bills relating to a National Health Department. Dr. Stephen Smith thought that Dr. Woodworth's bill was the only one that could pass, and thus he sponsored it. But the act that Congress finally accepted in March, 1879, was sponsored by the American Public Health Association and drawn by Mr. Eaton. It transferred from the Marine Hospital Service all the health duties and powers hitherto conferred upon it, including all maritime quaran-

tine. Surgeon General Woodworth, a fine, sincere, talented man, had worked very hard for his bill and sincerely believed it was the best that had been proposed on national health legislation. Upon its failure, he collapsed, and within a few days he was dead.

The new act created a National Board of Health, consisting of seven physicians, no two from any one state, and a representative from the Army, the Navy, the Marine Hospital Service, and the Department of Justice. The members were appointed by the President and had the following duties:

1. To obtain information on all matters affecting the public health.
2. To advise governmental departments, the commissioners of the District of Columbia, and the executives of the several states on all questions submitted by them—or whenever in the opinion of the Board such advice may tend to the preservation and improvement of the public health.
3. Report to Congress a plan for a national health organization, special attention being given to quarantine and especially regulations to be established between the states, as well as a national quarantine system.

The following men were appointed to membership on the Board, and \$50,000 was appropriated for this work:

J. L. Cabell, J. S. Billings, T. J. Turner, P. H. Bailhache, S. M. Bemiss, H. I. Bowditch, R. W. Mitchell, Stephen Smith, S. F. Phillips, and T. S. Verdi.

The Board was an excellent one. Dr. Cabell, professor at the University of Virginia, was one of the most distinguished physicians of his day; Stephen Smith had done more to advance the public health than any man in the nation. Henry I. Bowditch, the Boston representative, was the pioneer in state health work in New England; J. S. Billings was to become the foremost physician of the land.

On June 2, 1879, Congress passed a second act, giving the new Board wide quarantine powers, and appropriated

\$500,000 for its quarantine work. This act had one clause which proved to be a fatal weakness: It gave these quarantine powers for a period of four years only, and a reenactment bill was necessary for a continuation of the work.

The National Board started its work most auspiciously. Eight quarantine inspectors were employed, covering the coast from Maine to the Rio Grande. Familiar names appear: Elisha Harris was assigned the coast from Portland to New York; A. N. Bell was given Norfolk to Brunswick, Ga., and Jerome Cochran, from Key West to Pensacola. In theory, the National Board aided states in enforcing their quarantine regulations, but in practice, since the National Board had the funds, it dictated the quarantine policies. From January 12 to June 30, 1880; the Board spent \$284,000, and during the next fiscal year, \$202,000 was expended for hospital construction and quarantine purposes. It sent a yellow fever commission to study conditions in Cuba, with Dr. Chaille of New Orleans as Chairman and Dr. Sternberg as Secretary. The Board members themselves were very active on a variety of sanitary matters and published some excellent reports.

But serious trouble was not far off. Dr. Joseph Jones was secretary of the Louisiana Board of Health. He was a man of tremendous energy and strong opinions. He had been an officer in the Confederate Army, and was an indomitable foe to anyone who did not agree with his ideas. Although he had lost the Civil War, he had not lost his belief in States' Rights. He wrote Dr. Cabell in the summer of 1880:

"The Board of Health of the State of Louisiana cannot delegate its quarantine powers to any other organization, whether created by a National Congress or by other individual States."*

* National Board of Health, "Reports" 1880, page 605.

Shortly thereafter an epidemic broke out in the delta below New Orleans. Sternberg visited the zone and made the diagnosis of yellow fever. Samuel Bemiss, the member of the National Board who lived in New Orleans, wrote Dr. Jones the facts in a rather superior manner, stating that the National Board could be drawn upon for necessary funds for disinfectants, sanitary inspections, and for necessary equipment in order to control the epidemic. He stated just how funds were to be allotted and indicated that approval of all expenditures must, of course, be in his hands. This statement has a familiar sound to present-day health departments that receive federal grants-in-aid, but most modern state health officers are not so conscious of the principle of state sovereignty as was Dr. Jones. Dr. Jones responded that the Louisiana Board of Health had investigated the "*malaria fever*" of the rice lands and that necessary health measures had been taken, thus putting young Sternberg in his place. Sternberg made a second visit and again made a diagnosis of yellow fever. A neutral commission was then selected to study the matter. Dr. Mitchell, the Board member from Memphis, and Sternberg went along. The commission decided that the epidemic was malaria,* and Dr. Jones won the first round.

On July 15, 1880, a vessel called the "Excelsior" came to New Orleans with a cargo of coffee. Five days later one of her crew developed yellow fever. She had been held in quarantine a few days in the lower delta, and it is possible that her crew was infected from the cases diagnosed as yellow fever by Sternberg. Meanwhile, the coffee had been sent to a number of interior cities.

* From the description of the cases, Sternberg may have been wrong. It is more probable that there were cases of both yellow fever and malaria at the same time. Diagnosis was purely symptomatic and very difficult.

Dr. Bemiss, National Board member in New Orleans, telegraphed the facts to the health officials of these various cities. This was an unprecedented thing to do and was an interference with commerce. Dr. Bemiss writes:

"A great deal of excited discussion arose in consequence of this action of the National Board in relation to the cargo of the 'Excelsior.'"

The upper Mississippi Valley states had no confidence in the Louisiana quarantine service and stood by the National Board in this controversy. But apparently Dr. Jones was more than a match for Bemiss. He stung like a hornet, for he was never satisfied with one encounter, but always returned to the attack.

In 1881, the National Board appointed as its inspector a worthy opponent for Dr. Jones in Dr. S. E. Chaille. He had been a famous Confederate War officer, was a professor in the Medical College, and perhaps the most beloved physician of Louisiana. His appointment appealed to local sentiment and was a very wise move on the part of the National Board of Health. But trouble began for Dr. Chaille almost at once. To forestall any outbreak and to be prepared for emergencies, before the yellow fever season began he asked the Louisiana Board of Health for the right to station his inspector down the river at the state quarantine, and also asked to have access to the New Orleans death reports. The Louisiana Board of Health were indignant, and felt that they had been grossly insulted. They would have no federal "spies" in their midst. But the New Orleans Auxiliary Sanitary Association—a group of business men—supported Dr. Chaille. One suspects they did so because of the threat of embargo from the Sanitary Council of the Mississippi Valley, which had insisted upon federal supervision of the

Louisiana quarantine officers. Dr. Cabell wrote from Washington directly to the Governor of Louisiana requesting his coöperation. The Governor supported the National Board of Health, and Dr. Jones lost the second round.

His own letters testify that he did everything in his power to make life miserable for Dr. Patton, the federal inspector who was stationed at quarantine.*

The year 1882 was the most active and productive of the National Board of Health. The report of the year is a book nearly six inches thick devoted to various sanitary investigations that were carried out by members of the Board, or that were authorized by the Board. Many of these studies are basic, well planned, and efficiently executed. But the gadfly at New Orleans was more tormenting than ever before. All states, says the report rather plaintively, are willing to coöperate with the National Board except Louisiana.

On May 1, before the yellow fever season began, Dr. Chaille wrote the new Governor of Louisiana asking if the National Board inspector could again be stationed at state quarantine. The Governor replied in the affirmative, stating:

"The inspector is expected, in accordance with the original authorization of Congress, to aid and assist our state quarantine officer. It must be understood that he shall not supervise, control or direct the actions of the state quarantine officer."

Dr. Patton was again assigned to quarantine by Dr. Chaille, but Dr. Jones kept up a continual battle against what he considered the effrontery of the federal government in invading his state and attempting to supervise his work.

* See Dr. Chaille's defense of Dr. Patton in letter to Dr. Jones, Sept. 5, 1881, p. 339 of *Reports of National Board of Health*. See also Vol. III, compiled works of Dr. Jones.

Dr. Chaille wrote at the end of the summer:

"I shall hope never again to occupy such unpleasant and detrimental circumstances as my office has brought me during the past two years."

When Congress was considering the appropriation for the National Board that summer, the New Orleans press accused the Board of "manufacturing yellow fever in the Mississippi Valley" to frighten the national legislative body to give it more funds and continue its work. A telegram from the National Board Secretary, Dr. Turner, was misquoted by one of the New Orleans papers to say that if the National Board was not supported, it would be necessary for the upper Valley states to resort to the "trusty shotgun" for the purpose of enforcing quarantine against yellow fever. The Louisiana State Board of Health flew into a rage and passed the following resolution:

WHEREAS: the National Board of Health by the emission of such innuendos and incendiary publications violates the conventionalities of official intercourse in a gross and unwarrantable manner, showing what it would do if it once had the power, and reflecting most aristocratically upon the self governing power of the American people — —

BE IT RESOLVED, that the telegram of Secretary Turner be copied and forwarded to President Cabell, with the request that in the future their communications be couched in more decorous language when alluding to this Board.

Few of the friends of the National Board seem to have realized that while the controversy in New Orleans was raging, a much more dangerous foe within the shadow of the National Capital was quietly plotting its destruction. When Surgeon General Woodworth died, a young Marine Hospital Service officer, John Hamilton, was appointed to the position. His rise in the Service had been phenomenal. He had taken no part in the advance-

ment of public health in the nation and was not even a member of the American Public Health Association. He had no knowledge or experience in the field of quarantine, nor, in fact, had he any knowledge or experience in the fields of sanitation and public health. He was forceful and intelligent, and must have been an expert in political intrigue. He knew that if Congress did not reenact the quarantine law by June 2, 1883, the National Board of Health must terminate. Since the bill of April, 1878, had granted quarantine powers to the Marine Hospital Service, these functions would revert to him and to the Marine Hospital Service if the National Board of Health was discontinued.

Quietly and effectively he did his utmost to bring discredit upon the National Board of Health and its activities. He accused the members of the Board of misuse of funds, of extravagance, and incompetence. He insinuated that leading sanitarians, such as Rauch, Kedzie, Elisha Harris, and Wirt had used funds of the Board to corrupt local health officers, and claimed that they had packed the Indianapolis meeting of the American Medical Association in securing endorsement of the National Board.

Congress gave consideration to extension of the activities of the National Board of Health in 1884. Colonel George Waring, Secretary of the Board in 1884, in his remarks before the Committee of Public Health of the House of Representatives, stated:

"In Dr. Hamilton I knew was centered the only effective opposition to the National Board of Health. I accused him of misrepresentation to lash him into appearance before this Committee rather than, as has been his practice hitherto, 'at the button hole.'"

Waring pointed out that Hamilton's quarantine work (in the Brownsville epidemic) "has been injudicious and unskilled," and insisted that the Marine

Hospital Service had no facilities at all except curative ones, and was engaged in one specific duty: the cure of sick sailors.

The defenders of the National Board of Health were good sanitarians but poor politicians. It was true that the members of the Board had been overzealous; they had tried to move too rapidly, and in this sense they had been extravagant. They had made the fatal mistake of encroaching on the prerogatives of the individual states, and the representatives of these states in the Congress did not relish this taste of federal centralization of power. There had been no more widespread epidemics, and memory of past disaster is notoriously short. The real statesman profits by past experience and plans for the long future, but not the politician.

Despite the support of the American Public Health Association, the Sanitary Association of the Mississippi Valley, the State Departments of Health of Massachusetts, New York, Illinois, Michigan, and many others, the re-enactment bill of June 2, 1883, failed to pass. A small grant of \$10,000 was given the National Board to continue its investigations and advisory functions, but all its quarantine powers reverted to the Marine Hospital Service.

Stephen Smith, of all the national sanitarians, saw the importance of a *National Public Health Service*. He had favored Woodworth's bill in 1879. He was cited by Hamilton in 1883 as favoring transfer of the National Board's powers to the Marine Hospital service; but Smith, in his address before the Public Health Committee of the House of Representatives in 1883, makes his stand clear. He wished to confer all public health duties and powers on the National Board of Health, but to incorporate in the National Board the officers, the staff, and the activities of the Marine Hospital Service. He foresaw that Con-

gress would lose interest in the National Board of Health, but would continue to support a service agency that had full-time career officers and was incorporated as an integral part of national government machinery.

In retrospect we realize that Stephen Smith was right. The unwieldy board of experts, each living in a different community and attempting to carry out administrative duties, with no cohesion, no real unity of opinion and no central authority, was an impossible administrative machine. A centrally guided service, such as actually developed, had unity and purpose, but unfortunately lacked intelligent leadership. The public health policies for a great nation for many years were determined solely by the opinions—sometimes the whims and personal prejudices—of a single individual. It would have been a much better plan if Dr. Stephen Smith's half formulated plan of 1883 could have been carried out, thus salvaging the really important features of the National Board of Health and incorporating in it a service agency with full-time personnel, an *esprit de corps*, and a strong central administrative machine. The members of the Board of Health, selected by the President of the United States because they were public health experts, should have been continued as a Board of Health and should have served as a permanent policy-forming body, advising and aiding their administrative officer. The Marine Hospital Service was the most logical existing national agency with which to vest this national public health function. The Surgeon General should have been made the executive officer of the Board, and all actual administrative responsibility should have been centered in him. It was a great opportunity to have organized a close-knit, effective National Health Service, but there was no single man who had the vision or the power to solve this simple problem.

The Preventive Medicine Program of the United States Army*

JAMES STEVENS SIMMONS, M.D., PH.D., D.P.H., Sc.D.

Brigadier General, Army of the United States; Director of the Preventive Medicine Division, Office of The Surgeon General, U. S. Army, Washington, D. C.

THE Medical Department of the Army is responsible for the health of all our military personnel. Its principal mission is to keep the soldier fit to fight. A complex organization is required to accomplish this mission, and at present the Medical Department includes the following important branches: The Medical Corps, Dental Corps, Veterinary Corps, Nurse Corps, Sanitary Corps, Medical Administrative Corps, the Physical Therapy Aides, and the Dietitians.

Obviously the services rendered by the Medical Department are manifold. This organization is intimately concerned with the health and welfare of the soldier from the moment of his induction until he leaves the service. It establishes and maintains the physical standards used in the selection of all Army personnel, and it examines every soldier inducted. It is concerned with seeing that he is provided with satisfactory shelter, that he is fed an adequate, well balanced diet, and that he takes the proper physical exercise. It is concerned with his habits and hygiene, with the sanitation of his environment, his immunization, and with the innumerable other measures required to protect him against disease. If he becomes ill or injured the soldier

receives excellent medical attention in a modern army hospital, and when he eventually leaves the service he is given a final physical examination by the Medical Department.

The most glamorous of these activities in time of war is the medical and surgical care of the sick and wounded. The life of a medical officer assigned to duty in an active theater of operations is packed with drama intense enough to satisfy the most romantic cravings for adventure. The devotion to duty of the officers of the Medical Department has always been a credit to our profession. Their heroic achievement—in the evacuation and care of the wounded, in salvaging the human wreckage of battle, in snatching the gravely injured from the brink of death, and in returning the wounded to active duty—constitutes a thrilling epic of war. It affords a satisfying contrast to the necessary but unpleasant task of destruction that is basic to all war.

There is, however, another aspect of military medicine that is less dramatic but equally important. It is to this, the preventive aspect, that attention is invited. To keep at all times the maximum number of men in condition to perform their military duties requires that these men be protected from the numerous hazards with which they are surrounded, hazards which if not controlled may so seriously deplete man

* First lecture in the sixth series of lectures under the John Wyckoff Lectureship, established by the Phi Delta Epsilon Fraternity, College of Medicine, New York University, April 15, 1943.

power as to render military operations ineffective or impossible. Lord Disraeli, that shrewd and farsighted statesman of the Victorian era, has been quoted as stating that "the prime function of government is the protection of the health of its people." A civil population that is not healthy cannot be prosperous and will lag behind in the economic competition between nations. This is even more true of a military population, for any army that has its strength sapped by disease is in no condition to withstand the attack of a virile force that has conserved its strength and is enjoying the vigor and exhilaration of health.

History is replete with dramatic examples of the influence of disease in shaping the course of battles and campaigns. From the days of ancient Greece and Rome to the present time epidemics have played a vital rôle in determining the outcome of military operations. The world has never seen, and probably will never see, the military genius who can ignore this important factor. Alexander felt the withering blight of disease. Hannibal was cheated of his conquests by illness in his Army. More than one of the crusades of the Middle Ages were turned back by the ravages of infection rather than the arrows of the Saracens. Napoleon, in his retreat from Moscow, felt the sting of disease and the crippling effects of physical deterioration. The last world war was prolonged in several theaters by the paralyzing action of disease. In Macedonia, malaria immobilized large British, French, and German forces for about three years. Eighty per cent of 120,000 French troops were hospitalized; and among the British with a strength of 124,000 there were 162,000 admissions for malaria between 1916 and 1918.

We may admire the technological advances that have produced the powerful weapons of today, but there is one

factor which has not changed since the day of the crossbow and the sword. That factor is the need for man power with which to operate these modern instruments of destruction. Therefore, this World War presents no exception to the generalization that the protection of the health of troops is an essential part of any well planned military operation. The nature and extent of our current operations are such that never before has it been so necessary to guard our soldiers against disease. The destructive power of modern weapons and the mobility of troops is now so great that a military force, disabled by disease, is relatively more defenseless than ever before, when confronted by a healthy opponent. Moreover, the wide geographic distribution of our present operations has introduced many new health hazards. American soldiers are scattered around the globe. Literally they are spread from Greenland's icy mountains to India's coral strand.

Today we are faced with the danger of operating in tropical areas that present some of the most difficult health problems that ever confronted a military force. Even under conditions of peace, life in the tropics has usually been attended by greater health hazards than life in the temperate zones. The backward civilizations encountered in many of these hot climates testify to the debilitating effects of the local diseases. Poor sanitation is the rule—poor sanitation that exerts an obviously bad effect on the native populations and is even more dangerous to the incautious visitor. In such places the enteric and the insect-borne diseases are usually prevalent. Often they are so common that it is exceptional to find an uninfected native. Diseases that are medical curiosities in this country are matters of everyday occurrence. Even the tropical climate itself, with its high heat and humidity, constitutes a menace—one that the native has learned to

reduce by living a leisurely and ordered life, such as is not possible under military conditions.

We must remember, however, that the disease hazards of this war are by no means limited to the tropics. The present conflict is truly global and the military action extends from the equator to the Arctic circle. Wherever American troops are stationed they are exposed to dangers of infection incident to their physical and social environment. These are encountered first at home during the period of training and they are accentuated later in the overseas theaters. Military preventive medicine has as its main task the control of these hazards in order that man power may not be wasted through avoidable illness or death.

Obviously, this huge task of health protection is a responsibility shared by all Medical Department officers wherever they may be stationed. The medical officers assigned to duty with troops in the field constitute our first line of defense against disease. To this field personnel will always fall the task of putting into action such measures as are found to be most effective. The planning and the correlation of these activities are the function of the Preventive Medicine Division of The Surgeon General's Office. It is to this phase of the preventive program that this discussion relates.

THE PREVENTIVE MEDICINE DIVISION

During 1939, when the clouds of war began to gather, it became obvious that this country might ultimately become embroiled in a world conflict. The Surgeon General of the Army devoted increasing attention to plans for protecting the health of our troops under conditions of mobilization and war. From a small and rather informal beginning there evolved in his office during 1941 a special Preventive Medicine Division. This division has developed

into an organization which today covers a wide variety of fields all concerned with disease prevention.

The objectives of the division have been the maintenance and conservation of the health of the Army through the prevention and control of infectious diseases and the elimination of sanitary, occupational, and other health hazards. It has advanced toward this objective by the development of plans based on estimates of future possibilities, by the constant accumulation of scientific knowledge from all available sources, and by the vigorous application of the most promising control procedures. In this work the division has utilized every available facility and has enlisted the services of many highly qualified persons. In general the nature of the work is the administrative management of all phases of preventive medicine. This division is concerned with the following activities: the establishment of policies and procedures; the development of control measures; the procurement and assignment of specialized personnel; the collection, analysis and distribution of information on medical and sanitary conditions in all parts of the world; and the initiation of research on problems of immediate significance to the Armed Forces. It has maintained close liaison with numerous governmental and civilian agencies. These include the National Research Council, the Committee on Medical Research of the Office of Scientific Research and Development, the Bureau of Medicine and Surgery of the Navy, the U. S. Public Health Service, the Pan American Sanitary Bureau, the Office of Coördinator of Inter-American Affairs, the International Health Division of The Rockefeller Foundation, and most of the scientific societies in the fields of biology, medicine, and public health. Association with all of these agencies has been extensive and intimate.

The Preventive Medicine Division now includes the following branches: Sanitation, Sanitary Engineering, Epidemiology, Laboratories, Military Occupational Hygiene, Venereal Disease Control, and Medical Intelligence.

The Sanitation Branch—The Sanitation Branch is of great importance. Sanitation has long been recognized as the backbone of preventive medicine. In civil life it is accepted as a commonplace and inevitable attribute of civilization. Thus we often fail to appreciate how much our physical well-being depends on the routine performance of the homely functions of sanitation. Its adaptation to the conditions of military life, especially to operations in the field, involves highly specialized technics, although the underlying principles remain the same. Neglect of sanitation almost inevitably results in outbreaks of preventable diseases. Obviously, therefore, it is essential to maximum military effectiveness.

The foundation of sanitation is cleanliness. It is logical therefore that, in the Sanitation Branch, much attention has been devoted to the study, development, and promotion of measures which will provide for the soldier a clean healthful environment. The officers of this branch maintain close contact with conditions in the field through the careful analysis of the routine and special sanitary reports which are received from all military organizations at least once each month. This affords an excellent opportunity to assist the medical officers of the various organizations in the solution of their sanitary problems. The branch is also concerned with the formulation of general policies on sanitation and hygiene. Liaison is maintained with the Quartermaster, the Engineers, and various other branches concerned with food and water supplies, sewage and other waste disposal, housing, ventilation, clothing, and insect control; also with numerous other

agencies engaged in the development of more effective sanitary methods.

The best of food can easily become a vehicle for disease if it is contaminated through improper handling. The sanitation of food handling is therefore a matter of great concern to this branch. Those of you who are familiar with the difficulties of food sanitation in the permanent installations of civil life will appreciate the infinitely greater obstacles to be overcome in dealing with this complex problem under field conditions in the Army, especially in the combat zone. However, these obstacles must be overcome, for in any military force the slightest relaxation of sanitary discipline may produce enteric infections severe enough to immobilize the entire force.

The sanitation of water, which is intimately related to food sanitation, is also a major responsibility of this branch. All recognize the important rôle of water as a vector of enteric diseases; but few, who have not seen the conditions under which many of our troops are living abroad, can appreciate the degree to which the water supplies of those areas may be polluted with human excrement. The Sanitation Branch is concerned with the purification of such water under the most trying field conditions. Obviously this requires technics entirely different from those employed in civil life or in fixed military installations. These technics must be so simple that they can be performed by the average soldier; the equipment must be easily portable so that it can be carried under conditions of combat; and the procedures must be so effective as to decontaminate, and render safe, water from sources that would be rejected under the normal conditions of civil life. This branch is also concerned with the development of policies and methods which will insure the sanitary disposal of sewage and other wastes.

Closely allied with the sanitation of water, food, and wastes, are the problems connected with the control of the horde of insects that are present in many areas. As a rule flies are only a nuisance in our modern cities. On the other hand, they may constitute a serious menace to health in areas where sanitation is primitive or neglected.

Many of the biting insects carry serious diseases and therefore their eradication or control is of the greatest importance. For this reason the Sanitation Branch is concerned with the development of measures that will protect troops against mites, ticks, lice, bedbugs, fleas, mosquitoes, sandflies, and various other kinds of gnats and biting flies. Another important function is the control of the rodent reservoirs of disease. The measures used are quite varied, depending on whether the troops are living in permanent camps or in the field. In the vicinity of fixed installations they include extensive insect and rodent control projects. Under field conditions reliance must be placed on the personal protection of troops through the use of our highly effective new repellents and insecticides.

Sanitary activities on Army posts in the continental United States are supplemented by work done outside this area by civilian health agencies. Early in 1940 The Surgeon General of the Army made arrangements whereby the U. S. Public Health Service, working through state and local agencies, has provided for extra-military sanitation in civilian areas around all Army reservations. This activity has been coordinated through the assignment of U. S. Public Health Service officers to the headquarters of each Service Command for cooperation with the Army Surgeon.

*The Sanitary Engineering Branch—*The Sanitary Engineering Branch deals with the engineering aspects of sanita-

tion. The officers assigned to this branch are concerned with the sanitary control of the large water purification plants and sewage disposal plants of permanent camps, posts, and stations. The Corps of Engineers is responsible for the actual construction and operation of these facilities, but the sanitary engineer is concerned with such supervision and advice as may be necessary to protect health. This arrangement may appear to be complicated. However, the situation is a counterpart of the civil arrangement whereby the construction and maintenance of city water supply and sewage disposal systems are handled by the city engineer or by a special board, while the board of health advises concerning sanitary aspects that may affect the health of the community.

The officers of this branch have initiated surveys of practically all the water supplies and the sewage plants serving Army posts in this country. They have found many defects and have collaborated with the Corps of Engineers in their correction. They are also concerned with the sanitary facilities in the large hotels and other dormitories which have been taken over by the Army and with special methods for safeguarding military water supplies from sabotage.

Another important function is close collaboration with the Corps of Engineers in the initiation and planning of insect and rodent control programs for posts in the Zone of the Interior. During the last two years more than 400 sanitary engineers and 140 entomologists have been commissioned and assigned to key positions throughout the Army. In 1941 the Army's mosquito control program in the United States cost about 2 million dollars, and the malaria rate was 1.8 per 1,000. In 1942 the cost was 3 million dollars and the malaria rate only 0.6 per 1,000. This was the lowest rate ever recorded

for the Army. This campaign was supplemented by the extramilitary mosquito work of the U. S. Public Health Service.

The Laboratories Branch—The Laboratories Branch is concerned with the formulation and the accomplishment of policies and activities designed to provide, maintain, and improve the various types of medical laboratory services required for the Army. Diagnostic laboratory services are made available for all Army hospitals; and laboratories for epidemiological, sanitary, and research work are also provided for the prevention of disease both at home and abroad. The quality of the services afforded by both types of laboratories depends on the adequacy of trained personnel, quarters, equipment and supplies, and the use of suitable technical methods. Earlier there was some difficulty in obtaining sufficient numbers of physicians trained in bacteriology and the other laboratory specialties. This problem has been solved in part by the utilization of non-medical specialists who are commissioned in the Sanitary Corps and assigned to work in laboratories under the supervision of Medical Corps officers. The Laboratories Branch has been of great assistance to the health program of the Army by providing an effective laboratory service.

The Military Occupational Hygiene Branch—The Occupational Hygiene Branch has been established since the beginning of the present emergency in order to safeguard the health of civilian workers in the essential war industries owned and operated by the Army. These workers who are manufacturing the weapons of war are just as essential to the war effort as are the soldiers who use the weapons. The soldier temporarily incapacitated by measles or a bayonet thrust, represents a loss to the war effort. So also the munitions worker who is absent from his or her work bench or the assembly line, because of typhoid fever or smallpox,

represents an inexcusable delay in the output of the essential instruments with which the war must be won. The protection of the health of these workers is therefore as much a matter of concern to the Army as is the health of the soldier.

This branch, working through Service Command Surgeons, supervises the emergency medical service in Army operated industrial plants and depots. It is also concerned with the hygiene of working conditions and the elimination of occupational health hazards. It maintains a central industrial hygiene laboratory which makes surveys of all our military industrial plants in order to improve the health of the workers. This branch has also been concerned with the procurement and assignment of experienced industrial medical officers.

Another important activity which has been developed under this branch is the organization at Fort Knox of the Armored Force Medical Research Laboratory. This laboratory has been established for the purpose of studying the hazards intrinsic in the operation of tanks and other mechanized warfare vehicles. These hazards include exposure to toxic gases, heat, dust, and trauma in tanks. Much valuable information concerning the operational dangers of mechanized warfare is being afforded by the studies made in this laboratory.

The Occupational Hygiene Branch maintains liaison with all other governmental and civilian agencies concerned with industrial hygiene. It has also assumed responsibility for the supervision of industrial health and environmental sanitation in certain contractor-operated plants located on War Department property. These plants are surveyed by the Industrial Hygiene Division of the National Institute of Health, with which close contact is maintained. It is estimated that the

Army's Occupational Hygiene Branch is concerned with preserving the health of more than 1½ million civilian employees in the Army operated plants alone.

The Epidemiology Branch—The Epidemiology Branch is responsible for the formulation of general policies concerning the control of infectious diseases. Its officers assemble and analyze data on the current prevalence of disease among troops, and investigate any abnormal incidence of infection. This branch keeps its fingers on the pulse of the Army, and is ever watchful to detect the first signs of danger from communicable diseases, in order that it may advise the local medical officers as to the measures required for control. It includes several sections, one of which is concerned primarily with the administrative and technical supervision of the Army's immunization program.

Early in 1940 The Surgeon General began to expand this immunization program in order to meet the new disease conditions of war. It now includes the following important procedures: All troops are vaccinated and revaccinated against smallpox, typhoid fever, and the para-typhoid fevers A and B. They are also immunized actively against tetanus, using a series of injections of liquid tetanus toxoid. This new measure is considered to be of the greatest value in the protection of the wounded. An effective vaccine against yellow fever has been made available and the Army has used this material to protect all of its troops in areas where yellow fever exists. Promising vaccines against typhus fever are now available and in use among troops going to regions where louse-borne epidemics of this disease are apt to occur. Provisions have also been made to use cholera and plague vaccines in the attempt to immunize individuals going to regions where these diseases are endemic. The exact degree of protection afforded by these typhus,

cholera, and plague vaccines is not known, and therefore the Army does not rely on the use of vaccines alone, but insists on the additional use of all indicated sanitary procedures. This section also assists in planning for the procurement, supply, and distribution of all the prophylactic biologicals used by American troops throughout the world. The present immunization program is considered one of the most potent weapons being used for the preservation of the health of the Army. Undoubtedly many thousands of American soldiers will owe their lives to the protection afforded by these immunizing agents.

Another important section is the one devoted to the control of tropical diseases. Since the Spanish American War, the Army has had a rich experience with such diseases in the tropical possessions which were acquired at that time from Spain. Consequently, medical officers of the regular army have made important contributions to our knowledge of tropical medicine. As we passed from the recent period of emergency into the present state of war, American troops were sent to many new tropical frontiers, first in the western hemisphere and later throughout the world. This introduced new and difficult problems in disease control.

The most important tropical disease to which United States troops will be exposed is malaria, which is the most widespread disabling disease in the world. Other insect-borne diseases are potentially dangerous and so are the intestinal infections, especially cholera, the dysenteries, and the diarrheas. The tropical disease section has exerted leadership in planning an effective military program for the control of such diseases. This program includes the organization of special teams of highly trained control officers for duty in overseas theaters, the initiation of extensive programs for the training of medical

officers and of civilian teachers in tropical medicine, the maintenance of liaison with those responsible for the procurement of the special personnel, equipment and supplies needed, and coöperation with the research agencies concerned in the development of new procedures for the control of tropical infections among troops. The infection rates in certain overseas regions where protection is difficult are relatively high. However, in spite of the exaggerations of certain sensational writers, both lay and medical, a relatively effective program of disease control has been provided for all such areas.

The Civilian Board for the Control of Epidemics—One of the most effective agencies developed as a part of the Army's preventive medicine program, is the "Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army." This board which was established by the Secretary of War in January, 1941, on the recommendation of The Surgeon General, is an example of the effective collaboration which has existed between the Preventive Medicine Division of the Army and the leading civilian specialists of the country.

The board operates as a part of the Preventive Medicine Division under the immediate supervision of the Assistant Director, Colonel S. Bayne-Jones. The central body of the board consists of the following seven members: Dr. Francis G. Blake, President, Drs. Oswald T. Avery, Alphonse R. Dochez, Ernest W. Goodpasture, Kenneth F. Maxcy, O. H. Perry Pepper and Andrew J. Warren. In addition there are 104 members of commissions, making a total of 111 civilian specialists in infectious diseases who are attached through the board to the Office of The Surgeon General. All of these members hold appointments as special consultants to the Secretary of War.

The broad objectives of the board

are two-fold. Primarily its function is to act as an advisory body to The Surgeon General and to be ready at any time for temporary duty in the field in order to combat epidemics or threatened epidemics. Its other function is to conduct continuing investigations, either in the field or in civil institutions, on practical problems of military preventive medicine. The Surgeon General has repeatedly called on the board or groups of its members for advice and assistance. In addition to projects for investigation, approved in advance, numerous emergency field studies have been made by members of the board and its commissions at the request of the surgeons of Service Commands or of Posts in various parts of the Army. The arrangements for these field investigations have such flexibility that it is possible at times to place consultants in the field or to have them on their way to posts within a few hours after requests for assistance have been received and approved. At present ten commissions are organized under the board. These are as follows: (1) The Commission on Acute Respiratory Diseases, of which Dr. John Dingle is the Director. This group is now stationed permanently at Fort Bragg, N. C. (2) The Commission on Cross Infections in Hospitals, under Dr. Oswald H. Robertson. This group is concerned with the study of various methods for reducing the number of pathogenic bacteria and viruses in the air of hospitals and barracks. (3) The Commission on Epidemiological Survey was formerly under Dr. S. Bayne-Jones and is now under Dr. Francis G. Blake. It has been concerned with continuing bacteriological surveys among troops in various parts of the country, in order to establish base lines during inter-epidemic periods for comparison with the prevalence of types of bacteria in periods of outbreaks of respiratory diseases. It is hoped that useful predic-

tions may be made in advance, on the basis of changes in prevalence of such organisms as streptococci, influenza bacilli, or meningococci, and that the information gained may be applied promptly to the control of epidemic diseases. (4) The Commission on Hemolytic Streptococcus Infections, formerly under Dr. M. Henry Dawson, now under Dr. Chester S. Keefer, is concerned with the control of streptococcal infections of the respiratory tract. (5) The Commission on Influenza, under the directorship of Dr. Thomas Francis, Jr., is organized to assist in dealing with influenza on a country-wide scale in Army posts if an epidemic should occur. (6) The Commission on Measles and Mumps under Dr. Joseph Stokes, Jr., is concerned with problems of the epidemiology, prevention, control, and treatment of these diseases. (7) The Commission on Meningococcal Meningitis, formerly under Dr. Perrin H. Long, and now under Dr. John Phair, is concerned with the development of effective methods for the control of that disease. (8) The Commission on Neurotropic Virus Diseases under the direction of Dr. John Paul, is concerned with studies of poliomyelitis, lymphocytic, choriomeningitis, equine and encephalomyelitis, St. Louis encephalitis, and other diseases. (9) The Commission on Pneumonia is headed by Dr. Colin MacLeod. (10) The Commission on Tropical Diseases, under Dr. Wilbur A. Sawyer, includes specialists in many important tropical diseases. It has been used extensively in the field.

It may be stated that this board represents a powerful part of the Army's defense against disease. It places at the disposal of The Surgeon General the best available skill and facilities, for research in military preventive medicine. The members of this board are not only helping to win the war, but they are contributing ma-

terially to our knowledge of infectious diseases.

The Venereal Disease Control Branch—The Venereal Disease Control Branch is responsible for the formulation of policies, and plans for the prevention of such diseases among troops. It is concerned with the procurement and training of special venereal disease control officers for assignment to key positions throughout the Army. Working through these officers the branch has as its objective the execution of a rigorous control program based on the following: the repression of prostitution; the encouragement of continence; provision of prophylaxis for those exposed; collaboration with civil authorities in the detection of sources of infection; provision of medical care for the infected; and, finally, the education of all military personnel regarding the strategic importance of preventing venereal infections. Obviously this program requires close collaboration with all local and federal health and law enforcement agencies. During World War I the venereal diseases caused more loss of time than any disease except influenza. It is gratifying to report that in no month of the current conflict has the admission rate been as high as the lowest monthly rate of the last war. Contrary to popular notion, the prevalence of venereal infections, acquired in the Army, is not appreciably greater than that for comparable groups in the civil population.

The Medical Intelligence Branch—The Medical Intelligence Branch is a unique part of the Preventive Medicine Division. This branch was started during 1940 in order to collect, assemble, and disseminate in the Army specific information about health and disease conditions in foreign countries. The need for such information is obvious. It affords an exact basis for planning the measures and equipment necessary to protect our forces in foreign countries.

For example, knowledge that malaria exists in a certain country is of limited value unless it is supplemented by information as to the anopheline vectors peculiar to that region and their breeding and feeding habits. The need for such exact detail is apparent when one realizes that two closely related malarious regions may be infested with mosquito vectors so different in their habits, that control measures which are effective in one of the areas might be actually harmful in the other.

The information is collected from many sources including medical libraries, current literature, Army and Navy Intelligence Service, other governmental and civilian health agencies, and individuals recently returned from foreign countries. In many instances such information has been supplemented by the reports of Army sanitarians sent abroad to make personal investigations and sanitary surveys.

After collection, the information is studied and used to prepare comprehensive health surveys. Each survey includes data on the topography, climate, and population of the country; also a brief section dealing with the public health services and the facilities for sanitation and medical care; and detailed information concerning the important diseases and their epidemiology. These surveys form the medical sections of the War Department strategic surveys, and are furnished to the commanding officers and the medical officers of all forces going to foreign countries. They are also used as a basis for the specific recommendations made for the protection of the health

of all troops sent abroad, and they are sent to various teaching institutions in the Army and are used extensively by individual officers preparing for foreign duty. The activities of the Medical Intelligence Branch are an important part of the preventive medicine program.

CONCLUSION

In this brief discussion of the Army's program of preventive medicine details have been avoided. Only some of the broad objectives and the general scope of the program have been considered.

The Division of Preventive Medicine has been created in The Surgeon General's Office to plan for and exercise general supervision over the preventive aspects of military medicine. It serves as a policy forming agency which can coordinate the experience of the forces in the field and provide for the development of sound preventive practice.

In the evolution of its present program the Army has had the assistance of numerous civil agencies, both official and voluntary, and the advice of countless civilian specialists. To read the roster of those who have participated in this coöperative program would mean essentially calling the roll of the country's outstanding medical institutions and investigators.

The execution of the preventive medicine program is a responsibility which must be shared by every individual in the entire military force. The effectiveness with which it is executed will depend on the intelligence and zeal with which individual medical officers carry out the primary mission of the Medical Department.

Home Drying Methods and Their Effect on the Palatability, Cooking Quality, and Nutritive Value of Foods*

ESTHER L. BATCHELDER, PH.D.

*Bureau of Home Economics, United States Department of Agriculture,
Washington, D. C.*

AS my title suggests, I am presenting home dehydration as a problem somewhat apart from commercial dehydration and commercially dehydrated products. The reason is doubtless obvious: relatively crude equipment, lack of technical knowledge or skill on the part of the homemaker, limitations of time and space, and variability in quality and amount of material to be dehydrated are factors which tend to limit the degree of uniformity which can be expected in home dehydration at present.

Our research is definitely aimed at improvement of home dehydration equipment and at making available practical directions for home dehydration which will enable the homemaker to develop skill and to make the best use of her space, equipment, and home-grown produce. At the same time, we have been studying the edible quality and to some extent the nutritive value of home-dehydrated fruits and vegetables. The present results in this field of research give us merely a picture of what may be expected in home-dehydrated products made according to present knowledge and facilities. We

believe that edible quality and nutritive value of home-dehydrated foods may be improved as better methods and better equipment are made available to the homemaker.

Work on edible quality includes problems of rehydration and cooking of the plain material and of its preparation in various recipes. Palatability studies are of prime importance because they are used (a) as a means of evaluating the dehydration process itself, (b) as a means of evaluating different storage conditions, and (c) as a basis for judging the value of the rehydrated and cooked product and of the recipes developed for the use of dehydrated products. Obviously, the most nourishing food is of no avail if it does not taste good enough to be eaten by the family.

Nutritive value is important because, once a product of acceptable edible quality has been produced, the question immediately faced is that of whether the eating of a dehydrated food assures the consumer of nutrients similar in kind and amount to those found in the same food when fresh, canned, or frozen. Some nutrients which are destroyed by heat, oxygen, or light are known to decrease after ordinary cooking or canning. The fact that some nutrients may be lost during dehydra-

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

tion is not, therefore, a reason for condemning such a process. It is, however, reason for continuing to work on improvement of the process until the greatest possible conservation of nutrients, consistent with good keeping properties and good edible quality, is attained.

At the Bureau of Home Economics and in three cooperating states—California, New York, and Texas—much attention has already been given to home dehydration. Due to scarcity of strategic materials, it was not possible this year for many families to obtain pressure cookers for processing non-acid foods. By 1943 it is possible that cans and gaskets of suitable quality may also be difficult to get. Starting with the literature available from *Farmers' Bulletin 984*¹ and from the various experiment station and extension service leaflets, the preparation, drying, and storing of various fruits and vegetables was begun. In this phase of the work, the dehydration process itself was carried on so as to permit some direct comparisons of the nutritive value of fresh and corresponding dehydrated samples of vegetables of known variety and cultural history.

EQUIPMENT AND METHODS

Driers—Two cabinet driers were constructed for use over kerosene heaters according to directions by Cruess,² issued by California Agricultural Extension Service. Recently a new edition of this leaflet has been issued.³ Trial runs on one sample of beef and several vegetables were made according to Cruess's directions. With the cooperation of the Housing and Household Equipment Division of the Bureau, modifications based on this experience were made in the construction of the drier. This is described in a recent bureau publication.⁴

A drier of tunnel type with electric heater and fan which had been de-

veloped experimentally by the Rural Electrification Administration and sent to us for practical drying tests was also used. This was modified by the Housing and Household Equipment Division in the light of our exploratory experiments. Two other electric driers were used for some tests but were not available for intensive experimentation. A few tests using range ovens have been made. One drier which sits on the top of a gas range is now being tested.

Choice of foods for drying—Sweet potatoes, snap beans, and leafy greens were first chosen for particular attention because they represented different types from the point of view of nutritional value and drying qualities. Quantities of the first two of known variety and cultural condition were available by courtesy of the Bureau of Plant Industry. As time permitted and foods were available other kinds were dried.

Preparation for drying—Using existing directions for home and commercial drying as a basis, procedures for each food studied were adopted or developed with the manifold purpose of:

1. Preparation in a form suited to quick and efficient drying
2. Preservation of edible quality
3. Preservation of nutritive value
4. Use of existing home kitchen facilities and minimum of special supplies or equipment
5. Economy of housewife's time

Frequently, a compromise has to be made in final directions for drying because a method which is optimum for one purpose is least desirable for another.

Objective 1 usually is accomplished best by dividing material into small pieces for quick penetration of heat in the pretreatment and quick evaporation of water during drying.

Objectives 2 and 3 are accomplished best by the method which assures quick and complete destruction of enzymes during pretreatment, minimum loss of

soluble nutrients, and minimum temperature and length of time for drying. Steaming until almost done was the most effective method found.

Objective 4 is accomplished by avoiding when possible the use of special chemicals such as lye or citric acid (commonly used for commercial dehydration) and improvising ways of steaming relatively large quantities with materials available in most rural homes.

Objective 5 is frequently difficult to reconcile with objective 1, since peeling, cutting of small pieces, and careful spreading on trays are time consuming. Methods were avoided, however, which seemed to require a prohibitive amount of preparation time.

Sampling—Careful plans were made to assure adequate sampling of the food as purchased, as prepared for drying, after pretreatment, after drying, and for storage studies. Results in our own and other laboratories indicate that proper sampling is often difficult and that improper sampling leads to conflicting evidence and undependable conclusions.

The drying process—Automatic recording of temperatures measured by thermocouples placed at various points in the loaded driers was arranged by the Equipment Division. Measurements by means of household thermometers were made at intervals. These make possible a comparison of the drying temperatures found effective in each home drier with those appearing in the literature as applying to elaborate commercial dehydrators. Eventually some translation of the safe temperature range as measured by the thermocouples into terms of a household thermometer placed at a convenient place on the drier will be made. More exhaustive studies of physical aspects of the running of the driers are contemplated by the Housing and Household Equipment Division.

Each food presents a new problem in each drier. In general, existing directions were followed when available and in the light of experience modifications were made.

In the kerosene drier, the Cruess directions were to change trays every half hour so as to avoid overheating of the food on the lower trays and inadequate heating of the trays above. Longer time intervals throughout or at the later stages of drying have been tried and recommendations developed as a result of these investigations.

No changing of trays is necessary in the modified electric drier.

Tests for dryness—Laboratory determinations for moisture were made at the end of the drying process as a check on the rule of thumb directions given for homemakers in *Farmers' Bulletin 1918*.

Packages and storage—In general, the packages of the dehydrated product were determined by what would be available to the homemaker. Glass jars, tin cans, or other containers which could be hermetically sealed were used. Also waxed paper cartons, paper bags, etc., were used for storing miscellaneous samples.

Due to limitations in amounts of dehydrated material for direct comparison on storage studies, only two variables could be studied on each run, e.g., 2 packages at one temperature for 1 length of time, 1 package at one temperature for 2 lengths of time, or 1 package at two temperatures for 1 length of time. Temperature levels represented a range of from 0° F. to 105° F. Humidity was not controlled, but for the permeable or semipermeable containers, storage in the Beltsville laboratory represented high relative humidity a large part of the time.

PALATABILITY TESTS

Organoleptic tests are necessarily subjective in nature and it is difficult to

set up objective standards for evaluation of palatability. Judging of foods has long been a part of the work of the Food Utilization Section. Moreover, a judging panel of members of the Bureau of Animal Industry and Bureau of Home Economics staffs has been working for some years on meat and poultry tasting.

The dehydration work, however, presented such a large volume of tasting to be done on such a wide variety of foods, and the results of such tests were so important because they were the basis of decisions as to successful processing, that it was decided to develop if possible a more objective method of selecting judges and of setting up judging panels. For that purpose, a system was developed for testing individuals for their sensitivity to odors and to four basic tastes: sweet, sour, bitter, and salt.

On the basis of these tests, individuals who showed poor sensitivity were eliminated as judges. The others were called upon as needed and when available.

Cooked dehydrated products were scored by a panel of five judges for appearance, odor, flavor, consistency, and acceptability. The definitions of the judging terms are (1) excellent—quality equal to the best fresh, (2) good—satisfactory, (3) fair—below average, but not objectionable, (4) poor—objectionable but edible, (5) very poor—inedible.

Snap beans—Snap beans were not in prime condition when received. They rated "good" when cooked but fresh beans should be "excellent." Beans were shredded lengthwise, because in preliminary tests they were the only ones that retained any vitamin C. Snap beans were soaked in 15–20 times their weight of water (well covered) for 2 hours; then cooked in a covered pan with salt added, until tender. Butter was added.

They rated "fair" when dried as compared to "good" when fresh. Some experienced tasters considered the dried beans on a par with or better than canned.

After cooking there was considerable water remaining which had a strong, unpalatable flavor. This was discarded although it is obvious that soluble nutrients were discarded also. We plan to study more exhaustively possibilities of cooking so as to conserve both palatability and nutritive value in the food as served.

Beets—Beets, when fresh were scored "good" and maintained this score after precooking, dicing, dehydrating, reconstituting, and cooking. Precooked sliced beets of the same lot scored only "fair," however.

Carrots—These were scraped and then cut crosswise, diagonally, in lengthwise strips, shredded or diced. From palatability scores on the dehydrated product, it seems that crosswise slices, diagonal slices or shreds rate highest. These cuts reconstitute more completely and have a nicer appearance than the others.

Dehydrated carrots were soaked 1–2 hours in 10 times their weight of water and cooked until tender, from 4 to 24 minutes.

Sweet potatoes—Sweet potatoes were steamed until tender, peeled, cut lengthwise in slices $\frac{1}{4}$ inch thick, and dipped in a 2 per cent citric acid solution. The acid improves the color and gives a slightly sour flavor to the sweet potato.

Dehydrated sweet potatoes were soaked in 4 times their weight of water (just covered) for 1–2 hours or until plumped. They were cooked in the soaking water until tender, 10–30 minutes. The cooking water was discarded because of its sickening sweet flavor. Butter was added.

Most of the fresh sweet potatoes rated "good," only one was "excellent." After dehydration they rate

from poor to good, depending upon variety and method of dehydration.

KEEPING QUALITY OF DEHYDRATED VEGETABLES

Sweet potatoes—Dehydrated sweet potatoes stored in used coffee tins compared favorably with those stored in glass jars, tightly closed.

Nancy Hall sweet potatoes retained their original quality after 2 months' storage in a cardboard box at 74° F. and around 50 per cent relative humidity.

Mayonnaise jars without a rubber ring ranked as high as airtight fruit jars with a rubber ring and sealed with paraffin, stored at high humidity and a cool temperature.

The palatability of one lot of dehydrated sweet potatoes held at different temperatures packed in airtight glass jars showed after 2 months' storage edible quality ratings of "very good," "good," and "fair," at 45° F., 74° F., and at 100° F., respectively. These potatoes were not treated with citric acid before dehydration and therefore may have been more easily affected by higher temperatures than those treated with citric acid before dehydration. The palatability scores for a citric acid treated sweet potato show better keeping quality with no appreciable difference attributable to temperature or storage container. This citric acid treatment had been recommended by Caldwell in *Farmers' Bulletin* 984.

After 2 months' storage no differences were apparent between the sweet potatoes packed in an inert gas, such as nitrogen, and in air.

A study was made on sweet potatoes which had been held in storage at the Bureau of Plant Industry for about 6 months. They were in good condition. All were given the same pretreatment and were dehydrated under uniform conditions in the electric drier.

Five varieties of sweet potatoes ranging in color from deep orange through light orange and straw-colored to grayish-cream rated "fair" to "good" in palatability when (1) cooked fresh, and (2) precooked after citric acid dip. With but one exception, the citric acid treated sample rated the same or better than the plain potato, and in all cases the freshly dehydrated rated the same or better than the freshly cooked.

The palatability after 3 months' storage at 32° F. remained as good as before storage in two samples; but had dropped about 1 point in three instances (from "good" to "fair" in two, and from "very good" to "good" in one).

The storage study is very incomplete at present. Many foods have not been tested at all, and others have been tested after 1, 2, or 3 months only.

Greens—Mustard greens and chard were stored at room temperature in friction top tin cans and waxed paper cartons, respectively. Mustard greens showed no appreciable loss in palatability after 2 months' storage at room temperature.

After 2 months' storage at room temperature, the palatability of four samples of chard has decreased more than after 1 month in comparable vegetables. Further tests are needed before any definite statement of trend can be made.

Snap beans—Snap beans stored at 100° F. exhibited a color change to a tan shade whether stored in airtight or non-airtight containers. However, this lot of beans before storage were a yellowish green and not of very good quality.

In two preliminary experiments dehydrated beans have been tested after 6 months' storage. At this time they rated "fair" in palatability and were green in color. This is as good or better than most of the freshly dehydrated snap beans.

Since our data on the keeping quality of beans at various temperatures is very meager as yet, it is impossible to say that dehydrated snap beans deteriorate faster at high temperatures than low when packed in airtight or non-airtight containers.

NUTRITIVE VALUE OF HOME-DEHYDRATED VEGETABLES

Vitamin and mineral losses during preparation, dehydration, and storage were studied on several foods dehydrated by home methods in the Bureau of Home Economics laboratories. Calcium, phosphorus, and iron were determined on sweet potatoes, turnip greens, snap beans, and beets. These vegetables were steam blanched before dehydrating. The results showed a loss in mineral content of about 20 per cent, with the greatest loss occurring in phosphorus and the least in calcium. Theoretically, there should be no loss of minerals during actual dehydration. Mineral determinations are made, however, as a check on our sampling procedures.

The following are the findings on the vitamins:

Sweet potatoes—Steam blanched, no change in carotene; 20 per cent ascorbic acid is lost by this pretreatment. After dehydration by the Rural Electrification Administration electric drier, no loss in carotene; only 11 per cent of the ascorbic acid is retained; after cooking the fresh, dehydrated sweet potatoes, no change in carotene but considerable loss in vitamin C occurred. After 2 months' storage at 74° in glass jars under CO₂, kept in the dark, there is no change in these vitamins.

Turnip greens—During pretreatment, which was steaming, there was 25 per cent loss in the vitamin C content. Using the same method of pretreatment, but for a period of two to three times as long as the first, there was 67 per cent loss of vitamin C. A kerosene

drier was used and the drying period was about one-third longer than the one used on the sweet potatoes. Where the electric drier was used, there was about the same loss (65 per cent) in vitamin C.

Snap beans—During steam blanching, there was a 30 per cent loss of ascorbic acid. The drying methods consisted of (1) hanging on strings at room temperature for 6 days—all ascorbic acid was destroyed; (2) Rural Electrification Administration electric drier—35 to 50 per cent loss in ascorbic acid, depending upon the length of drying time.

In the string beans, the carotene content of the starting material was not too great to begin with; what there was appears to be practically all destroyed by these methods of drying.

Of interest in the case of the snap beans is the fact that during pretreatment, preparation of the vegetable is a factor as to the degree of loss in ascorbic acid. The loss of this vitamin is greater when the bean is steamed whole than when steamed shredded or cut. This may be explained by the fact that the heat penetrates the bean tissue to a greater degree in the shredded or cut bean, and destroys the enzyme more effectively.

CONCLUSION

In conclusion, it must be remembered that these results are only an indication of what happens during dehydration, since the methods have not yet been perfected. When these foods were dried, the number of foods was necessarily limited and our storage studies are still in progress.

In general, it may be said that many foods can be dried in simple apparatus to form a palatable product. The retention of nutrients depends considerably on the degree of control made possible by a given drier, but can be controlled to some extent by the use of

good methods of preparing for the drier. For any given food, the palatability depends not only upon the drying, but on the method used for rehydration and cooking, and on the quality of the fresh material. Moreover, no matter how good the freshly dehydrated product may be, adverse storage conditions result in loss in edible quality and nutritive value. The problem of home storage of dehydrated vegetables must not be forgotten, particularly since the kinds of container available are limited and facilities for cool dry storage are not available for many families.

Work is still going on in the bureau and in certain experiment stations. The

results from other experiment stations have not been reported here but will soon be available.

There is reason to believe that better driers, better methods of drying, and more information on necessary conditions for storing will be developed.

Blood and Malaria Parasite Staining with Eosin Azure Methylene Blue Methods*

R. D. LILLIE, M.D.

*Senior Surgeon, U. S. Public Health Service, Division of Pathology,
National Institute of Health, Bethesda, Md.*

IN 1939 it became apparent to those interested that many field workers in malaria were using Grüber's Giesma stain for thick film work, and were unable to obtain results satisfactory to them with the Giemsa stains then manufactured in the United States. The difficulty was that when staining at pH 7.0, which seems best for thick film work, the German stain gave a clear, light blue coloration to plasmodial and lymphocyte cytoplasm and a sharp reddish-purple chromatin stain, whereas American samples then available gave a grayish-lilac cytoplasmic coloration and a denser red-purple chromatin stain. This gray-lilac was difficult to distinguish in the similarly but less intensely stained background of detritus in the thick film, and from the gray-pink cytoplasm of red corpuscles at pH 7.0.

In attempting to solve the difficulties the available pure dyes of the methylene blue thionine series were tried in combination with eosin and with each other. To afford greater ease in manipulation, we decided to use the Nocht method, which consists in using 1:1,000 solutions of eosin and thiazin diluted in buffered water, on account of its extreme flexibility.

Azure B turned out to be the best single dye, although MacNeal and others had thought this dye of relatively low value. It was also found that the desired depth of cytoplasmic and background staining required a slight excess of basic dye over the amount equivalent to the eosin. This accords with Giemsa's original work.

Spectroscopic studies done at this time revealed that the imported Giemsa stain contained chiefly azure B and methylene blue, agreeing perfectly with our experimental findings.

Our first formulae were derived directly from the Nocht method. One consisted of methylene blue 270, azure B 200, azure A 50 and eosin 500 dissolved as such in 100 ml. of a mixture of equal parts of glycerin and methyl alcohol. This stain was highly satisfactory.

However, as soon as an attempt was made to translate this into commercial production, variation in dye content of the four dyes led to difficulties. So, believing that the precipitated eosinates would be of more constant dye content, further formulae were evolved on that basis, and the first few commercial samples were eminently satisfactory. Such samples consist basically of 50 mg. azure A eosinate, 250 mg. azure B eosinate, 200 mg. methylene blue eosinate and 100 mg. methylene blue

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

in 100 ml. of the glycerin and methyl alcohol mixture.

After a time this method in turn broke down and the spectroscope showed that the difficulty lay in qualitative variation in composition of the azure B. One of the methods of making azure B is to oxidize methylene blue to crude azure A with hydrochloric acid and potassium bichromate and then again to reduce this with formaldehyde by heating under a reflux condenser. This was supposed to yield only azure B. However, a trial of this reduction process in my hands has yielded on at least one trial almost pure methylene blue, as well as products spectroscopically intermediate between azure B and methylene blue.

It would appear that the commercial method of manufacture of azure B will have to be revised by introducing spectrographic control, by further study of the variation factors in the formaldehyde synthesis, or by going over to the partial-oxidation process which appears to yield quite constant products spectroscopically when the same proportions of chromate and methylene blue are used. This has been done and has been found to yield a more uniform product.⁹

However, with the coöperation of the Stain Commission and the dye companies, after excluding some samples which do not turn out well, we are now able to obtain on the market quite satisfactory Giemsa stain for blood and parasite work.

Turning to Wright's stain we find that commercial samples of this on the market, found in various laboratories and furnished for certification to the Stain Commission, vary considerably in staining capacity. Some samples yield pale blue nuclear staining with satisfactory light blue lymphocyte cytoplasm, good neutrophil and eosinophil granules and orange-pink-red corpuscles staining at pH 6.5 with a 1:2 dilution.

Such samples, though offered as Wright's stain, are essentially eosinates of unaltered methylene blue, or Jenner's stain. Spectroscopically these give absorption maxima between 660 and 665 for the thiazin, 515–518 for the eosin. I consider these unsatisfactory. Other samples give blue-violet to reddish-purple leucocyte and parasite chromatin, clear, light blue parasite and lymphocyte cytoplasm, good granules and orange-pink-red cells. Here absorption maxima range from 660 for the bluer samples to 645 or 650 for the redder. These are quite good for blood and parasite work. Still other samples give denser reddish-purple chromatin in white cells and parasites, more gray-lilac cytoplasm in lymphocytes and parasites, perhaps less satisfactory eosinophils, good azure granules and orange-pink-red corpuscles. Here absorption maxima range from 620 to about 640. Some workers prefer such samples for blood work, but they seem less satisfactory for malaria parasites, trypanosomes, etc.

Such variation occurs even in successive samples from the same manufacturer and appears to be inherent in the Wright method of polychroming. This calls for heating at about 98° C. for an hour, in relatively shallow layer, of 1 per cent methylene blue in 0.5 per cent sodium bicarbonate. Extended experimental work has shown that marked variations in such products are produced with variations in the amount of evaporation occurring, in exposure to air, in pH of the initial mixture, and apparently by taking the sodium bicarbonate out of different bottles.

However, by prevention of evaporation, by rigidly controlling pH by using standard buffer mixtures in place of the apparently variable sodium bicarbonate, and by close control of time, temperature, dye content of methylene blue and its concentration in solution, it is possible consistently to produce polychrome methylene blues in

the azure A or azure B range which will vary by less than 5 milli-microns in the position of the absorption band on repeated trial. So it would appear that, when the preference of workers as to color effect can be learned, it should now be possible to duplicate closely Romanowsky stains of Wright type in successive batches.

We have been greatly aided in these attempts at standardization of Romanowsky stains by study of their absorption spectra and the correlation of these with the staining capacity of the samples. It was my belief that a similar method of study would be valuable in determining the causes of deterioration of solutions in methyl alcohol or glycerin and methyl alcohol of these stains. Accordingly, studies were initiated last August using a number of samples of Wright's stain solution which had been on the laboratory shelves for intervals varying from 1 week or so up to over 3 years, as well as freshly prepared solutions of two samples, one with an original thiazin absorption maximum at 656, the other at 621 $m\mu$. To these latter various contaminants were deliberately added at 2 per cent concentration and spectra were run at intervals from 2 days up to 2 months at the present writing. The samples have also been tested as blood and parasite stains at the start and at the end of this period.

Summing up this work to date, old samples which no longer give satisfactory stains show absorption peaks generally below 615 $m\mu$, which represents a fairly pronounced shift from the original in many on which spectra were made when they were fresh. Crude chemical separations of some of these samples indicated formation of considerable amounts of methylene violets, apparently more than the remaining azures, though thoroughly satisfactory separations have not yet been worked out.

The deliberately contaminated samples all showed progressive shift of the absorption maxima toward 600 $m\mu$. This was fastest when repurified methyl alcohol was shaken with Na_2CO_3 and then filtered and used as a solvent. Acetone and formaldehyde both accelerated the shift, and methyl alcohol redistilled over silver oxide to destroy aldehydes showed a slower shift than commercial C.P. grade. Two per cent water had little appreciable effect. Formic acid seemed to act as a stabilizer for the thiazin, but this ruins the eosin component for staining purposes. However, after 2 months the repurified methyl alcohol solution had reached the same point as those contaminated with acetone or formaldehyde. Hence it would seem that the repurification of methyl alcohol was of little value.

However, the most obvious and striking finding was that solutions from the sample with an initial absorption peak at 656 were still good stains after 2 months in solution in pure, commercial, or acetone- or formaldehyde-contaminated methyl alcohol, while the solutions made from the sample with an initial maximum at 621 were all worthless in less than a month in spite of originally brilliant staining.

In the first instance absorption maxima were still above 630 after 2 months, while in the second they were below 615 in less than 2 months.

Hence it would seem that we should require initial absorption maxima for Wright's stains between 650 and 660 $m\mu$.

Radio Listening Habits of Mothers Who Attend Well Baby Clinics

MARGARET L. MURRAY AND C. E. TURNER, DR.P.H.,
F.A.P.H.A.

Health Educator, Boston Health Department, Boston, Mass.; and Professor of Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

HEALTH officers and health educators are concerned with the radio listening habits of mothers since, because of their positions in the home, they constitute a strategic health education audience. We undertook to secure information on this topic in the Boston Health Units by interviewing mothers.

A series of 250 interviews, lasting about 10 minutes each, were conducted at eleven health units and baby stations over a period of nearly 2 months. Experimental interviews supplemented thoughtful planning in deciding what information we should seek, and how the interview could best be conducted. Leading questions were avoided. Freedom of expression was encouraged. The series of questions which the interviewer had in hand were used as a guide in informal discussions rather than as a formal questionnaire for which categorical answers were sought. The validity and reliability of the findings were tested by a comparison of the tabulations on the analysis of the first 125 interviews with the tabulations of the second 125 interviews. These were remarkably similar.

Two hundred and fifty mothers were interviewed in the sequence in which they happened to come to the clinic waiting room, and they represented, therefore, a fair sampling of the women attending well baby clinics in Boston. The mothers interviewed were

a young group, 81 per cent of whom were under 35 years of age. They had a total of 471 children; their families range from one to eight children; the children ranged in age from 2 weeks to over 20 years, but 45 per cent of all the children were infants.

WHEN DO MOTHERS LISTEN TO THE RADIO?

Every mother, except one, owned a radio and she was about to purchase one. Despite the fact that they were from the low income group, 30 per cent of them owned from two to four radios each, so that the group of 250 mothers possessed 336 radios. Forty-eight per cent of these radios were located in the kitchen and 17 per cent in bedrooms. This means the mothers can listen while doing housework in these rooms. Seventy-seven per cent of the women said they always do housework when listening and practically never sit down to listen to the radio when idle. Ninety-four per cent said that at least one of their radios is conveniently located for listening during the day. Seventy-two per cent of the mothers listen every day, while 87 per cent are regular evening listeners. Eighty-two per cent claimed to be the person who usually turns on the radio in the home. An added 12 per cent said that they "frequently" turn on the radio themselves.

Eighty-seven per cent select, at least

part of the time, the programs they hear instead of just tuning in regardless of the station to which the dial is turned. Forty-seven per cent of this group always select the programs to which they listen. Only 13 per cent of the mothers interviewed never choose the programs they hear. There is less selection of programs in the daytime than in the evening. Of those reporting specifically on daytime listening habits, 33 per cent select their programs. Of those reporting on evening listening, 79 per cent select their programs. Despite low daytime selectivity, there is no one station the favorite of the majority of the mothers; 56 per cent expressed a preference for a particular station for daytime listening; 90 per cent of these choices were divided about equally among three well known Boston stations.

Eighty-six per cent of the mothers listen to programs between 7:00 P.M. and 10:00 P.M., while 92 per cent listen at least some time between 9:00 A.M. and 12:00 noon. The latter hours represent the best choice of listening-time for a peak audience composed chiefly of women.

ATTITUDES TOWARD HEALTH PROGRAMS

We sought to find out from the mothers whether they would like a health program, and if so what would be their preference as to the type of program presented and the hour preferred. In examining the data presented from this phase of the study, the reader should bear in mind that there may be a sharp difference between what the mother thinks she might like and what she would listen to if it were on the air. As a matter of fact, their expressed preferences do not square too well with their present listening habits.

The majority, 88 per cent, expressed themselves enthusiastically in favor of a health program, 10 per cent stipulating that they would listen if

the program proved interesting and entertaining, as well as valuable. Only 2 per cent of the interviewees said they would not listen to a health program. Fifty-eight per cent of the women prefer their health program to be on the air between 8:00 A.M. and 12:00 noon, while 19 per cent would find the hours between 6:00 P.M. and 10:00 P.M. most convenient. The remaining 23 per cent prefer afternoon hours. It is evident here that three times as many women prefer morning hours to evening.

The fifteen minute programs are the present favorites of the mothers, notably the so-called "soap operas" and the homemaking programs planned for women. Thirty-eight per cent of the mothers reported hearing at least one of the homemaking programs; 56 per cent told of following the serial dramas sponsored by the soap companies; and 11 per cent selected this latter form as their favorite of all types, while 6 per cent said they do not like the soap operas. Dramas of other types, broadcast both day and night, are enjoyed by 59 per cent of the mothers. Twelve per cent selected drama as their best liked program, while only 1 per cent said they do not like to hear stories on the radio. A low number of interviewees, 9 per cent, reported ever listening to any form of educational broadcast, and only two mothers chose this style as their favorite.

Some of the mothers contradicted their expressed tastes when choosing the style they preferred for the health education broadcast. Thirty per cent asked that the health program be presented as a talk, although only 9 per cent of them listen now to any form of educational program. They qualified, however, that the talk be "interesting—not dull or monotonous." What constitutes any of these qualities is an individual matter. It is difficult for a sponsor to satisfy all listeners. The interview was preferred by 15 per cent

and the discussion by 6 per cent. The former, particularly, is adaptable to health education material. Twenty-seven per cent chose the drama as the form most desired for reception of the health broadcast. As we recall from above, over one-half of the women listen to dramas and 23 per cent chose a dramatic form as the one best liked, while less than 1 per cent prefer educational programs. In view of these facts, we are not convinced that the health "talk" is the medium of choice.

Next, the mothers were asked what topics they would like presented in a health program. Extensive health knowledge was not to be expected in this group, and the lack of such information was reflected both in their inability to select health topics and in comments made during the interviews. One-third of the mothers had no topic to suggest. The other two-thirds suggested topics that fit into one or more of the following categories: food and nutrition, child training and growth, budgeting, clothing, personal hygiene, mental hygiene, communicable disease and household hints. As would be suggested by the fact that they were attending well baby clinics, most of the mothers wanted information about babies. Many did not seem to recognize their own health problems, for some who said they had no need of special help had very evident dental caries, eyestrain exhibited by frowns and

squints, underweight, poor personal hygiene, and other correctable conditions. Those who suggested a subject usually added that any topic both practical and timely would meet a need and would prove interesting.

SUMMARY

From a study based on 250 interviews with mothers who attend well baby clinics it appears that nearly all mothers can be reached by radio. The morning is the most favorable time for mothers to listen, 10 o'clock being the hour of choice by the greatest number of mothers. Although more mothers (30 per cent) suggested health talks than any other single form of presentation, the number suggesting either drama or interview-discussion totaled 48 per cent. This preference and their present listening habits both suggest that the program using more than one voice (interview or drama) should be widely used.

Building an audience will be necessary regardless of the station from which the program originates. This may be carried out through health department personnel and by posters in health units as well as by spot announcements and other common forms of publicity.

The careful measurement of a well developed morning radio program for mothers is needed to indicate its value in the general health education program.

Surveys of the Nutrition of Populations^{*}

2. The Protein Nutrition of a Rural Population in Middle Tennessee

JOHN B. YOUMANS, M.D., E. WHITE PATTON, M.D.,
W. R. SUTTON, PH.D., RUTH KERN, AND
RUTH STEINKAMP

Department of Medicine and the Department of Biochemistry, Vanderbilt University, Nashville, Tenn.

IN a previous paper¹ the general procedures and methods of a survey of the nutrition of a population in Wilson County, Tenn., have been given together with a description of the population and the results of the survey as they concern calories. The present report deals with the protein nutrition.

METHODS

Dietary: There were no special procedures with respect to the dietary study which require comment, the record of food consumption being obtained as previously described. Values for the protein content of the food were taken principally from *Laboratory Handbook for Dietetics*, by Mary Davis (Swartz) Rose.² When necessary these were supplemented by values from *The Fundamentals of Nutrition*, by Hawley and Maurer-Mast,³ *The Farmer's Bulletin, Rabbit Raising*, U. S. Department of Agriculture,⁴ and *The Structure and Composition of Foods*, by Winton and Winton.⁵ In a few instances when reported values were not available, values were arbitrarily assigned. In no case

were such instances of sufficient importance to modify the significance of the results. Details of the values are given in the working tables.[†]

History and Physical Examination—The only practical evidence of protein deficiency which can be obtained from the history and physical examination in a survey such as this is the occurrence of edema not attributable to other causes. This was, therefore, a point of particular inquiry in the history and on the examination. The usual clinical manifestation of edema, pitting on pressure, served as the sign of abnormality.

Laboratory —Serum proteins were determined in part by the macro-Kjeldahl method using Howe's procedure for separation of the protein fractions,⁶ and in part by the biuret technic as described by Robinson and Hogden.⁷ The Kjeldahl procedure though reliable, accurate, and a standard procedure, is costly in time and reagents. The biuret test was found to be reliable with "normal sera." However, extensive studies on sera in disease other than protein deficiency revealed discrepancies when compared

^{*} The Studies referred to herein were conducted under the auspices of the International Health Division of the Rockefeller Foundation of New York City by the Nutrition Unit of the Departments of Medicine and Biochemistry of the Vanderbilt University School of Medicine, Nashville, Tenn.

[†] Copies of these tables are much too lengthy for publication with these reports. They can be furnished by special arrangement by writing to the authors, as may copies of record forms used.

with duplicate Kjeldahl determinations. Therefore, while the procedure appears to be satisfactory when applied to an essentially "normal" population in which only an occasional false value might be gotten, it does not appear as reliable for general use as the Kjeldahl procedure.

RESULTS

The results are shown in the accom-

panying tables and charts. The total intake of protein was low in a large number of the subjects (Table 1). By far the majority had an intake less than 70 gm. which is the minimum recommended allowance of the Food and Nutrition Board for any except children under 10 years and adult women, for whom recommended allowances are 60 or less. Many had an intake of less than 50 gm. Low intakes (below 50

gm.)* were more frequent in Negroes than whites, 59 and 32 per cent respectively. In white children under 13 low intakes were found in from 4 to 12 per cent. Ten, 13, and 9 per cent of white males 13 to 21+ in ascending age groups

* Approximately $\frac{2}{3}$ recommended allowance Food and Nutrition Board

had low intakes compared to 58, 24, and 44 per cent of white females respectively. Corresponding values for colored are 61 to 92 per cent in the children, 36, 24, and 27 per cent for the colored males and 85, 62, and 69 per cent respectively for the females. The smallness of some of the groups

may account for some of the fluctuation, but the pattern is obvious.

Similar deficiencies were found in respect to animal protein (Table 2) with again the colored showing a low intake (less than 20 gm.) more often than the whites (63.9 and 30.1 per cent respectively). Sex and age differences

were observed as for total protein. Intakes less than 20 gm. were recorded in from 31.8 to 36.1 per cent of the white children between 4 and 12, while among the white males the incidence was 9, 10, and 15 per cent in ascending age groups compared with 63, 35, and 41 per cent for white females of the

corresponding ages. A similar pattern but a greater frequency is found in the colored. The children 4 to 12 showed an intake of less than 20 gm. in 82.6 to 84.6 per cent, colored males, 50, 42, and 52 per cent in the ascending age groups, and colored females 71, 60, and 64 per

cent. Again some of the groups are rather small.

A history of edema was obtained from 49 white and 33 colored subjects. By far the greatest number were adult females (41 white and 20 colored) with only 5 white and 10 colored males, 21

years and over, reporting this symptom. Only 3 colored children (7 to 15) and 3 white children (16 to 20) were included. Edema was found on the physical examination in 37 subjects, 25 white and 12 colored, or approximately 3 per cent of each group. However, again those with actual edema at the time of the examination were mostly women (19 white and 12 colored), with 6 white men making up the remainder. Furthermore, all but 1 were adults and

all but 6 were over 35 years old.

Only 5, or 10 per cent, of the white subjects, and 6, or 18 per cent, of the Negroes, who gave a *history* of edema actually had edema on examination. This is not surprising because the history included any previous time, while the examination disclosed the condition at the time of the examination only.

The serum protein values are shown in Tables 3, 4, and 5. Rather few ab-

* 25 Children under one year of age have been omitted

† M = Male; F = Female

normally low total serum proteins were found (32, or 3 per cent, in the entire group were below 6 gm. per 100 ml.), occurring in about 3 to 4 per cent of the various age and sex groups, except for white and colored children age 1 to 3 and colored girls 16 to 20 in whom it was 6.4, 12.9, and 8.3 per cent respectively (Table 3). However, serum *albumin* levels were below normal in a considerably larger number (Table 4). In 95, or 9 per cent of the entire group, the albumin was less than 4.0 gm. per 100 ml. These low values were more frequent in the colored than in the white subjects (13.1 and 6.9 per cent respectively), and the various age and sex groups showed rather striking differences. Serum albumin concentrations below 4 gm. per 100 ml. were not found or were infrequent in white and colored children below 13 years of age. The highest incidence was found in the colored girls 16 to 20 (29 per cent) and colored women 21+ (24 per cent). White females of the same age groups show 10 and 8 per cent respectively. An incidence of 5 to 14 per cent occurred in the white and colored males 13 to 15, 16 to 20, and 21+. In some of the groups the total numbers are somewhat small and in some the number of "unknown" is relatively quite large. In addition to those with clearly abnormally low values another considerable number had values at the border line (4.0 to 4.24 gm. per 100 ml.). The mean serum protein values however, were clearly in the normal range.

The distribution of serum globulin values is given in Table 5. Values less than 1 gm. per 100 ml. may well be errors. Concentration above 3 gm. per 100 ml. were found twice as frequently in the colored as in the whites.

DISCUSSION

These data show an intake of total protein below the recommended allow-

ance of the Food and Nutrition Board* in a very considerable number of the subjects, with many below the generally accepted minimum for satisfactory protein nutrition under usual dietary conditions. Moreover, comparison with the mean total calories of these subjects suggests that the deficiency is greater than first appears. As is well known, the adequacy of the protein intake depends to a large extent on the total calories. In adults especially, rather low intakes of protein are adequate to maintain nitrogen balance, preserve nitrogen stores, and provide for adequate protein nutrition if a large calorie intake from other sources supplies all energy needs and protects protein from being burned as fuel. This assumes of course that unusual demands for protein do not exist (growth, disease, lactation, etc.). Furthermore, much of such minimal amounts of protein must be of high biologic value (animal protein). Neither condition is fulfilled in this instance. Deficiencies are found in the intake of calories, in the absolute sense as well as relative to the protein intake, and the intake of animal protein is low (less than 20 gm.) in a very considerable proportion of the subjects. As might be expected, the protein intake showed a close and direct relation to total calorie intake.

In spite of the apparently severe restrictions in the intake of protein, the number of subjects with abnormally low serum proteins is not very great. While a hypoalbuminemia in 9 per cent of the total population is significant and important, and an incidence of 15 to 30 per cent in certain age groups even more impressive, the serum protein values fail to reflect as great a deficiency of protein as appears from the dietary studies. This lack of correspondence is further shown by a failure to demonstrate any correlation be-

* National Research Council

tween the serum albumin levels and such factors as the total caloric intake, total protein intake, and animal protein intake.

Attention should be called to the different significance of total serum protein and serum albumin. Abnormally low albumins were found three times as often as abnormally low total protein. Total serum protein is the sum of the albumin and globulin fractions. Globulin is relatively much less affected by nutritional deficiencies than is albumin, but on the other hand, is more affected by such factors as infections, etc. Both globulin and albumin fractions have a *range* of normal concentration over which they vary but not necessarily in the same direction. Total protein likewise has a *range* of normal concentration. It is, therefore, possible to have an *abnormally low* albumin combined with a rather *high normal* globulin to give a normal total protein. This occurs rather frequently in mild nutritional hypoproteinemia, which makes it important to determine the protein fractions as well as total protein. In this survey 89 per cent of the instances of hypoalbuminemia were accompanied by *normal* total serum proteins. Had not protein fractions been determined these instances of hypoproteinemia (hypoalbuminemia) would have been missed. Because of this and because serum albumin more adequately reflects protein nutrition it can serve alone for the serum protein values in such surveys of nutrition.

There probably are several explanations for the failure to find a correlation between the serum protein (albumin) and relative and absolute intakes of protein. Serum protein values are not solely a function of protein intake, at least in the direction of greater concentrations. Serum albumin values tend to fall within a narrow normal range which is relatively unaffected by any except rather extensive variation

in protein intake. This together with the inability to "break down" the values to a finer range and the relatively gross error in determinations of intake make it difficult to establish a close and direct correlation. Furthermore, serum protein values are subject to temporary variation having nothing to do with protein in the diet, the changes being sufficiently great to obscure any correlation within the range of usual normal values. Finally there is the matter of border line values and the protein reserve. Large numbers of the subjects had serum protein values close to the lower normal levels. In the absence of extra demands, normal or near normal levels may be maintained on rather small daily intakes of protein. Thus an appearance of normality is given. This constitutes however a reservoir of protein deficiency in a population, which becomes manifest under conditions of extra demand. Many of our subjects have customarily taken such a diet as is recorded here for years and their protein reserves often have been exhausted if one can judge from observations made in situations which make demands on the reserve, i. e., when they are ill.

It may of course be questioned whether the serum protein concentration is to be taken as an index of protein nutrition. If it is not, the lack of correlation between serum protein values and protein intake and the failure of the serum protein values to reflect to a greater degree the deficiency of intake would be well explained. It is well known that serum protein formation is affected by other factors. However, there is clear evidence experimentally at least, of a close relation between the dietary protein intake and the serum proteins. With severe restrictions the effect is manifest in the mass hypoproteinemia of populations (epidemic nutritional edema). In less severe and more chronic deficiencies

the factors of protein storage and the influence of other factors than protein deficiency must be considered in the interpretation of the data. If one may judge from clinical experience and the effects of more restricted dietaries on populations, a hypoproteinemia and especially a hypoalbuminemia may be taken as *prima facie* evidence of protein deficiency in studies of the nutrition of populations.

If this is true, the relation between the serum proteins and the history of edema and its actual presence on examination is important. Since this edema may be a result of hypoproteinemia and hence presumably an expression of protein deficiency, a rather close correspondence between edema and serum protein concentrations might be expected. As a matter of fact there was little relationship between the two. Only 12 of the 88 persons with a history of edema, 6 white and 6 colored, had serum albumin concentrations below the normal level (4 gm. per 100 ml.). Of the 37 subjects with actual edema at the time of examination only 5 had abnormally low serum albumin or total protein (in one the albumin concentration is unknown). On the other hand, of the 95 persons with hypoalbuminemia only 11 had edema or a significant history of edema.

There are, however, excellent reasons for this failure of correlation other than a lack of significant relation between the serum protein concentration and protein nutrition. First, the lack of agreement between the concentration of serum albumin and a history of edema is of no significance. Such histories are relatively unreliable, and the period of the edema may have had no relation to the time when the serum protein concentration was determined. Second, there are other causes for edema than lowered serum proteins and these must be eliminated before edema can be ascribed solely to a hypoalbuminemia.

Fortunately the methods used in the survey make it possible to detect such other causes of edema. Analysis of the 37 subjects with edema shows that of the 32 with normal serum proteins (albumin) all but 6 had a possible cause for the edema other than hypoalbuminemia, namely heart disease, including hypertension, renal disease, varicose veins, advanced age, etc. One of the 6 without such a possible cause had a concentration of total serum proteins barely within the normal range.

Finally, the failure of some with low serum proteins (albumin) to exhibit edema must be interpreted with due regard to the mechanism of the formation of edema in such cases. Although hypoproteinemia is the principal underlying cause for the edema, there are secondary factors which influence greatly the development of the edema and at certain concentrations of the serum proteins may determine whether edema will or will not occur (appear) and to what degree. Posture, tissue pressure, environmental temperature, and salt and water intake are such factors and at only slightly deficient concentrations of serum proteins in particular they may determine at a given time and in a given subject whether edema will occur or not. Certain of these factors operate in both directions. An increased water intake, for example, may precipitate edema at a level of plasma proteins which would otherwise not cause edema, while dehydration may prevent edema with proteins more severely subnormal. Analysis of the cases with hypoalbuminemia shows that in 85 of the 95 the concentration of albumin was only slightly below normal and was combined with a high normal (or in some instances an abnormally high globulin) to give a normal total protein. Calculation of the osmotic pressure in these cases.⁸ shows that in most of them the colloid osmotic pressure was sufficiently high to

make the occurrence of edema unlikely. Therefore, although the hypoalbuminemia indicates a deficient protein nutrition it was not sufficient in many of the subjects to cause an edema under the circumstances existing at the time of the examination.

In general then it may be concluded that the presence of edema on physical examination, while it may indicate a hypoproteinemia and hence a state of protein deficiency, cannot be accepted as such in the assessment of nutrition of populations unless other possible or likely causes of edema are excluded. On the other hand, a hypoalbuminemia of moderate to slight degree may not result in and may not be revealed by edema in a considerable proportion of the subjects.

SUMMARY

The results of a survey of the nutrition of some 1,200 persons in a general rural population in middle Tennessee with respect to protein nutrition (dietary intake, physical examination, and serum proteins) are reported. Frequent and severe deficiencies in the intake of protein, greater in the Negroes, the females, and certain age groups were observed. There was a significant incidence of protein deficiency as manifested by a hypoalbuminemia (about 10 per cent in the entire population), but it was not as great as might have

been expected on the basis of the dietary intake records. However, in some groups, notably colored females 16 and over, the incidence of hypoalbuminemia was very high, 24 to 29 per cent.

Edema was found on examination in a small number (about 3 per cent) but was often explainable by causes other than hypoproteinemia. No correlation was obtained between the dietary intake of calories or protein and the serum proteins. The significance of the results is discussed.

Field Experience for Health Education Personnel*

MINNIE KRUEGER OED, M.S.P.H., F.A.P.H.A.

Health Educator, Detroit Department of Health, Detroit, Mich.

A LARGE part of the effort put into health education is spent in mass processes such as news releases, lectures, broadcasts, printed material, exhibits, and posters. While these are all important from the point of view of keeping the public informed and health conscious, large-scale changes in behavior do not follow. The best opportunities are provided when we find small groups of individuals brought together by a single purpose. Adequately conducted discussions with these small groups will uncover the past experiences which are the foundations of their opinions and prejudices. They will provide opportunities for the discussion of controversial issues and allow for presentation of factual material by class or educator. They should help the individual think his problems through, and influence him to act in such a manner that his health and the health of the community will be improved.

In many communities all of the official and voluntary health agencies, various men's and women's clubs, and organized groups such as labor unions are forming health councils so they will be better prepared and able to care for the health and welfare needs of the community. They realize that any program of health education must be planned around a study of the needs

of the people and through these health councils, group needs may be considered. Health educators then can meet small homogeneous groups in their immediate neighborhoods. Through these health educators the desires of individuals may be presented to the health council for consideration, and community needs interpreted to the neighborhood groups.

Preparation of health educators must be given thoughtful consideration and critical analysis because of the great need to influence and mold public opinion at this time and the opportunities offered for preparing people to take part in planning community programs. Most schools and universities provide some courses which introduce the students to materials and methods in health education. They are designed to give health educators a working knowledge of available material.

In some of the courses a study is made of methods of presentation to different age, racial, or nationality groups; the development of some criteria for evaluating health information and materials; and consideration of measures for judging the results of health teaching. Sometimes these courses or allied courses cover more in detail methods of conducting group discussions; talks are planned and practice is experienced within the group. There is little opportunity, however, for field experience under supervision.

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

It was in response to this need that the Detroit Department of Health agreed to coöperate with Wayne University to provide the necessary field experience, training, and supervision. The Director of Public Health Nursing at Wayne University, and the Director of Nursing, and the Director of Health Education for the Department of Health planned the program. The course in Materials and Methods given at Wayne University is essentially the same as the methods course described above. This is a prerequisite to the course in field observation and practice teaching which will now be described.

The objectives for the field course are:

1. To acquire understanding and skill in handling group discussions effectively
2. To organize a teaching unit that will be use
3. To achieve ability to plan objectives for different learning situations and to understand what activities will tend to produce said objectives
4. To understand the needs of each group as well as the individuals in the group and to suit material to needs
5. To gain confidence in one's own ability to teach through practice in teaching under guidance
6. To gain knowledge of how to find, evaluate, and use factual material

The term educator as used here will mean the nurse, teacher, or community leader who is taking the course in preparation for teaching. The individuals this educator expects to have in future classes will be called students.

The course consists of eight 2 hour meetings with the instructor, four observations of group discussions conducted by qualified persons, writing of six discussion plans which are analyzed and corrected by the instructor, and finally conducting group discussions under supervision using these plans as a guide.

During the eight 2 hour meetings, the educators select a unit of learning. The expression "unit" implies whole-

ness or unity. It should present a unified experience which will give the student an understanding and control of a type of life situation. Each unit is broken down into as many separate parts as necessary for each to be easily understood and for all phases of the problem to be presented for discussion during the discussion period. Each part however should be a whole or total experience.

The educator, for example, may select for a unit of learning "Maternal Health." The parts could be:

First Discussion: How a baby develops in utero

Second Discussion: Why the expectant mother should see the doctor early in pregnancy

Third Discussion: Food needs of the expectant mother

Fourth Discussion: Healthful living during pregnancy

Fifth Discussion: What to do if the baby arrives early

Sixth Discussion: After the baby comes

After the educator has selected the unit of work, she will have to plan the objectives. There will be overall or central objectives for each unit and immediate or contributory objectives for each meeting. The objectives depend upon the needs, interests, and previous experiences of the students. The objectives are achieved if the discussions give the students knowledge, skills, abilities, or understanding to help them solve their problems. The educator may formulate objectives according to a student's needs, but they must be the result of some expression of desire on the part of the student and as such acceptable to her.

The educator should have a discussion plan prepared for each meeting. This is to help the educator ascertain if all the material is covered in the best possible manner and if it is going to meet the needs of the group. The discussion should be headed by the im-

mediate objectives. The body of the plan consists of subject matter, questions, and activities. All factual material should be included under subject matter. Statements should be briefly and simply stated so the educator may refresh her memory by a glance at the plan. Thought should be given to the type of questions to be asked to stimulate the desired response. They should promote thinking, provoke discussion, and at the same time bring out the theme of the lesson. The student must do certain things to bring about a change in behavior. These things we call activities. Problems and activities should challenge the student. They may consist of such learning experience as listening, enjoying, writing, reading, discussing, demonstrating, interviewing, going on excursions, or reporting. Because of activities the student gains a greater knowledge of the topic under discussion. They also should help her to develop some skill or ability to use her knowledge.

A great deal of material has to be covered to give the educator the background of facts and figures she will want and need. Each educator makes a bibliography of all the references used in preparation of the unit, giving title, author, publisher, date of publication, and pages. Knowledge of author helps to evaluate the material and a complete bibliography will be an aid when there is need to check a statement or when challenged for authenticity.

The work put into the discussion plans is for the purpose of achieving certain objectives. Evaluation and accomplishment can be determined to some extent by examinations, review, return demonstrations, and especially by new or changed attitudes as noted in discussion or practised by the group.

The eight class meetings then should help the educator conduct good group discussions by making her familiar with the following:

- Selection of a unit
- Suitable objectives
- Helpful procedures
- Reliable references
- Evaluation of results

Practice teaching is usually done in the clinics or in a community center where the group has already been organized by an experienced person. The educators teach six classes under supervision. Every class is not supervised, but as many as necessary to evaluate her ability. The director or supervisor of the center where the educator is to teach is familiar with the course content and objectives and she usually observes the first two lessons. She does this to help the educator orientate herself, to familiarize her with the program of the center, and especially to give her an understanding of the people, their needs and problems. The supervisor does not criticise methods of teaching or lesson content. In this way the educator will have time to gain poise and confidence before she is observed by those who may be more critical of her methods.

Usually the other four lessons are supervised by the course instructor. The director of public health nursing may observe or the director of health education for the department of health. If the classes deal with a special subject such as maternal or child health the director of child welfare may supervise some classes. Most of the courses already planned and carried out have contained one lesson on nutrition and the head of that division observes when that discussion is held.

Consideration is given not only to how the educator conducts the class but to the surroundings: Where is the class held? Have arrangements been made for some privacy? What visual material is used in form of posters and printed material? Will there be freedom from interruptions? In other words, does the environment

have an air of welcome and comfort that will encourage informal discussion? These features are discussed with the educator before or after class because they should have been a part of her preparation.

The educators have a number of books and pamphlets available at each meeting with which the class members can become familiar and which they can order if they desire. When enough copies are available some of the class members take a book home and make a report at a future meeting. References are selected with the intelligence, abilities, and needs of the group in mind.

Educators prepared with this practical experience will have a better appreciation of the basic needs and wants of individuals. Understanding these needs they will be better able to conduct discussions which will bring forth individual problems. Individual problems are usually interrelated and in turn closely connected with community health problems. When persons realize this they are more willing to work together for the good of all. This is a valuable contribution to the total community health program.

Educators will have some experience in applying the essentials and principles expounded by Overstreet,¹ Mueller,² Bryson,³ and Nash.⁴ Just as

it is necessary to know the basic needs and wants of individuals, so it is important to know when they are most receptive to suggestions and will more readily translate these suggestions into action. Nash in *Teachable Moments*, says, "The objective of all teaching regarding a subject is doing something about it. Information may be translated into behavior more easily when an individual has the power and the opportunity to act in behalf of himself or his family. The guidance must come from experts."

Teaching six lessons will not make an expert of these educators, but it will provide them with some technics which will be most helpful and practice will help to perfect these.

Dehydration Procedures and Their Effect on Vitamin Retention*

R. S. HOLLINGSHEAD

Bureau of Agricultural Chemistry and Engineering Agricultural Research Administration, U. S. Department of Agriculture, Washington, D. C.

THE term "dehydration," by strict definition, means the removal of water, regardless of the method applied. At the present time, according to general usage, the term is applied to processes by which the normal content of water in foods is reduced to approximately 5 per cent. At such low concentrations of water, foods will generally keep over considerable periods of time. This fact has been known from time immemorial, and as far back as written records go references are found of the preservation of dates, figs, and other fruits solely by sun drying. Our Western Indians and those in southern South America preserved meats by an air drying process. The flavor and texture of meats so preserved would not appeal to a connoisseur, but they did provide their users with an easily portable form of animal protein and one which could be preserved for extensive periods of time. It seems probable that few if any of the vegetables could be satisfactorily preserved solely by sun or air drying, since, in general, they would decompose before the moisture was reduced to a point where such decomposition could not take place.

In the making of both butter and cheese, the moisture content of milk is

reduced and the preservation of these products can be attributed, at least in part, to dehydration. Except for the Chinese method of keeping eggs by the use of lime, our older methods of egg preservation, such as they were, did not involve dehydration as an important factor. In more recent years, however, whole eggs, egg white, and egg yolk have been preserved by dehydration, and a large-scale industry is now in existence.

Many conditions brought about by the war have forced the application of dehydration as a method of preservation. The primary advantages of such a method are many. In the first place, weight can be reduced by approximately 90 per cent in the case of vegetables and by about 70 per cent in the case of most of the other foods. Without using compression on the dried products, the volume reduction of the dried product, as compared with the raw product, is not as great as the weight reduction, but it is still sufficiently large to warrant dehydration. If compression is used, much larger reductions in space can be obtained. Just how to obtain the compression of many products without injuring their quality is not yet known, but as an example of the possibilities, I might say that I have recently seen 5 lbs. of dried vegetables in a No. 10 can. Assuming a 10 to 1 drying ratio, this is equivalent to approximately 50 lbs. of the fresh vegetables, or roughly, one bushel. The

Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

packaging of dehydrated foods permits either the use of much smaller amounts of metal, if cans are to be used, or the possible elimination of metal containers and the substitution therefor of various combinations of sheets of glassine, cellophane, kraft or other papers, and possibly other plastic materials not yet in production.

As in the case of canning and quick-freezing, if a really high grade product is to be obtained, the manufacturer must go all the way back to the field where the crops are produced. The selection of varieties for a given area, which will dehydrate satisfactorily, is important. Harvesting obviously must be done at a predetermined stage of maturity. Once harvested, delays in all operations must be reduced to a minimum, although for root crops, such as potatoes, carrots, and beets, this speed is not so essential as it is for spinach, string beans, corn, and peas. Even in the case of the root crops, however, there is a limit to the period during which they should be held in storage.

On arrival at the dehydration plant, the products to be dried must be given essentially the same preparation as for canning or quick-freezing. These operations include washing, sorting, grading, peeling, coring, cutting or slicing and, finally, blanching. After these necessary operations have been completed, the actual drying is begun. Any one of a large number of methods can be used for the dehydration, but most frequently either tunnels or cabinets are used.

The drying operation is carried out until the moisture is reduced to the amounts permitted by the various specifications applicable to a given material. Having reached this stage of drying, the product is ready to be packaged.

If the whole operation of the production of dehydrated foods is consid-

ered as 100, this total is made up of preparation, 40; drying, 20; and packaging, 40. Expressed in another way, the preparation of the raw product and the maintenance of the qualities of the finished products are of about equal importance, and each is considerably more important than the actual method of dehydration used.

I have made brief reference to the several preliminary preparation operations. With the possible exception of blanching, the terms used, I believe, are self-explanatory. The operation of blanching consists of heating the raw product by immersion in hot water, by steam or by other methods, as may be necessary. The purpose of the blanching is to inactivate the enzyme system present, to set or hold the original colors in many cases, and to facilitate both dehydration and rehydration. There has probably been more discussion over the most suitable method of blanching than over any other operation. Experimental work carried on in the Bureau of Agricultural Chemistry and Engineering has shown that there is much less loss of ascorbic acid where steam is used for blanching than when hot water is used. The respective percentages of losses with these two treatments are as follows:

	<i>Steam Blanching</i> Per cent	<i>Water Blanching</i> Per cent
Kale	19	23
Beets	14	36
Potatoes	22	37
Cabbage	14	51

It has been suggested that by using the same water for blanching over and over again, only maintaining a fixed density, these losses might be reduced. Experimentally, our investigators have found that this is not the case.

To blanch satisfactorily with steam, it is essential to have sufficient steam to raise the temperature of the product to approximately 190° in about 1½ minutes, and it is rarely necessary to

extend the blanching time for more than 5 or 6 minutes. Ideally, the blanching should follow immediately after the other preliminary treatments, but where this is impossible, losses of ascorbic acid can be reduced by holding the unblanched material in a dilute salt solution. This practice, however, is not recommended and is condoned only under abnormal conditions which obviously will occur from time to time in any factory.

The following figures, based upon a number of determinations, indicate the vitamin C losses which occur as a result of steam blanching:

	<i>Per cent Losses</i>
Beets	14.8
Cabbage	18.3
Carrots	35.8
Kale	19.7
Mustard Greens	24.1
White Potatoes	22.5

Raw products from other sources than those used and other blanching methods will probably produce somewhat diverse figures, but these can safely be taken as a guide to average practices.

Without discounting at all the importance of the vitamin requirements of the human body, I might say that our experimental work has been directed toward the production of palatable, attractive foods and that the edibility of the product has been the main criterion of the success of our methods. Existing specifications do not call for any definite vitamin content of the dehydrated products. Because there are such wide variations in the vitamin content of the raw products, specifications based upon the known averages would be impractical. As an example of this, I might cite a case which occurred in our investigational work where spinach from two adjacent fields showed, respectively, 3 and 100 mg. of ascorbic acid per 100 gm. At the present time we are unable to give any

reason for this enormous variation. In another case, a lot of cabbage purchased for experimental drying was found to have practically no measurable content of ascorbic acid, although the general appearance of the cabbage was excellent and there was no reason to believe that the product had been subjected to any unusual or abnormal storage or other treatment.

I might say that our experimental work was undertaken to develop dehydration methods applicable to the foods in which the armed forces were particularly interested. These consisted of white potatoes, sweet potatoes, cabbage, carrots, onions, beets, and rutabagas. It will be noted that, with the exception of carrots and beets, none of these products is ordinarily canned and of the total production of beets and carrots, only a comparatively small proportion is canned under normal conditions.

I have called attention to the fact that the methods of dehydration are of less importance than the other fundamental factors incident to the production of dehydrated foods. I have also stated that the commonly used dehydration equipment is either the tunnel or the cabinet. I think that you may be interested in knowing more regarding the actual dehydration equipment.

The simplest form of dehydrator is the cabinet. This consists of a box-like room in which it is possible to control temperature, relative humidity, air volume, and air velocity. The properly prepared material is placed upon trays at a loading rate not to exceed $1\frac{1}{2}$ lbs. per sq. ft. Generally, the trays are stacked one above the other on a truck, and the truck pushed into the cabinet. After the doors are closed, the fans are turned on and the air current forced through steam radiators. When the operation first begins, quite high temperatures can be maintained on both wet and dry bulb thermom-

eters, for while in the wet condition, the product cannot be overheated and if the difference between the wet and dry bulb thermometers is not too great, hardening of the surface of the drying material will not occur. As the operation continues and the moisture is removed, it is necessary to reduce the temperatures quite a considerable degree. For each product there is a critical temperature which must not be exceeded when the product is dry. The critical temperatures run from about 135° to as high as 165° F. for most vegetables. The cabinet drier is not an efficient drying machine, but it has the virtue of being flexible though it must be operated on a batch cycle. It is not, therefore, essential to keep the factory operating 24 hours a day with all the disadvantages, particularly of obtaining labor, that such a type of operation entails.

For larger scale and continuous operations, the tunnel type drier is generally used. This is essentially an extension of the cabinet type in that, instead of one or two trucks each bearing 25 trays, there is sufficient length for 10 to perhaps 15 trucks. The same necessity exists for the control of temperature, relative humidity, air velocity, and air volume. Three types of tunnels are in use. They are known, respectively, as the parallel flow, the counterflow, and the center exhaust tunnels. In the first type, the hot air and the wet product enter at the same end of the tunnel; in the second case, the hottest, driest air meets the dried product coming out of the tunnel; and in the third, hot air, although at different temperatures, is introduced at both ends of the tunnel and is taken out in the center. There are advantages in both the parallel and counterflow types, and those advantages are used in the center exhaust type. Our engineers, and many of the other engineers in this field of activity, believe

that the center exhaust type is the most satisfactory, both as to its efficiency and the quality of the products obtained.

There have been introduced recently, but not yet given thorough trials, a number of other types of driers. Among these I might mention the continuous belt type for which large production capacity is claimed. A number of vacuum driers have been invented and a few seem to have merit, although in all cases the amount of metal required is large. For milk and eggs, the spray type of drier is the conventional one. In this operation, the liquid (after some condensation in the case of milk) is sprayed in at the top of a tall chamber and there meets a rising column of warm or hot air. By virtue of the rapid evaporation, the temperature of the product is not raised, although by the time it reaches the bottom of the chamber practically all of the moisture has been removed. Such a process, obviously, will produce only a powdery output. The various types of heated drums can be used for drying liquids. For some purposes they are quite satisfactory, but in all cases the dried product has no definite shape.

I believe it is rather obvious that any method of food preservation necessarily results in the loss of some of the original vitamin content. Our experimental work has extended into the field of packaging and storage. We have found that the vitamin losses in storage may be equal to, or even larger than, those incident to the preparation and dehydration of the various products. Part of the losses in storage are due to the effect of oxygen and part to the effect of moisture. We are definitely sure that there is a close relation between the amount of moisture in the product and the rate of vitamin destruction and the development of abnormal colors and flavors. Present specifications for dehydrated vegetables

permit from 4 to 6 per cent of moisture, except in the case of riced or pre-cooked potatoes where a 7 per cent moisture content is permitted. We have many indications that with lower moisture contents than those now provided, storage life may be extended, and it is more than probable that the existing specifications will be changed in this regard.

The necessity of keeping dehydrated products dry brings us to the question of packaging. The standard tin can probably represents the ideal package. This can be varied in size to meet the needs of the household or the needs of the mess cook who prepares food for standard units of around 100 men. Under normal conditions we would look no further than a tin can for a satisfactory package. However, these are not normal conditions. You, of course, know that only about $1\frac{1}{2}$ per cent of the "tin can" is tin, the rest being sheet steel. We have now more demands for steel than our mills can supply and, so far as possible, attempts are being made to use materials other than steel for food packaging.

Dehydrated foods can be packaged in non-metallic containers, since they are not subjected to the conditions which in a cannery require the use either of tin cans or glass containers.

The ideal package for dehydrated products must be moisture-proof, moisture-vapor-proof, insect-proof, and rodent-proof. The first two conditions can be fairly well obtained, and the third can be approximated by the use of certain non-metallic packages. As far as rodents are concerned, something other than the package itself must be used to give the necessary protection.

Some idea of the magnitude of the problem may be obtained by considering the conditions under which army supplies may be stored. These range from temperatures in the interior of Russia and Alaska of perhaps 40° be-

low zero to those of the Sahara Desert, and with humidities ranging from practically zero to 100 per cent saturation. A large amount of experimental work is going on not only in our laboratories, but elsewhere, to determine what packages can be obtained or devised that will adequately protect their contents under such wide ranges of conditions.

It has been noted that there is a close relation between deterioration and moisture content. If we start with a dehydrated food of 5 per cent moisture content, we believe that the product will be usable for one year if not more than 2 per cent moisture is added during the storage period. This gives us a fundamental requirement of the package in terms of water-vapor transmission. It is not safe to say that because a fresh sheet of packaging material transmits moisture at a low rate, a bag or package made from this same material will have the same water-vapor transmission characteristics. This fact is frequently overlooked in comparing packaging materials.

Since the subject of my talk deals with vitamins, I suppose I should not bring into the discussion the matter of rancidity. This, however, is so important in connection with many, if not most, of the dehydrated foods that I shall discuss it to some extent. Rancidity has undoubtedly limited the production and use of dried whole milk. It is for this reason that practically all of the dried milk used is made from skim milk. Obviously, in the case of meat, and particularly pork, the possibility of rancidity development during the period between dehydration and use cannot be neglected. Just how great this danger is, we cannot say at the present time. It seems probable that eventually antioxidants must be used in order to hold the product in an edible condition for the time required. Rather unexpectedly we have found that the

development of rancidity is not an unusual occurrence in dehydrated vegetables. Ordinarily, we do not consider fat as an important constituent of vegetables, and this is quite correct, as rarely if ever does the fat content exceed 0.2 per cent. In the fresh vegetable, however, this is accompanied by some 85 per cent of moisture. When the moisture is reduced to 5 per cent, necessarily the percentage of fat increases inversely and many of the abnormal odors in dehydrated vegetables have been found to be confined to the ether extract and are organoleptically identical with the odors associated with normal fat rancidity.

E. M. Chace, of the Bureau of Agricultural Chemistry and Engineering, summarized the results of our vitamin and other investigations at the June meeting of the Institute of Food Technologists at Minneapolis. This summary, ACE-172, "The Present Status of Food Dehydration in the United States," has been mimeographed and is available upon request either to the Bureau in Washington or to Mr. Chace at the Western Regional Research Laboratory, Albany, Calif. I have refrained from giving a mass of statistical and other information regarding the fate of vitamins in dehydration because the work was already well presented in this summary.

In summation, I feel that as far as dehydration is concerned, accent must be put upon the word "food"; and I think of food as something attractive

in appearance, color, flavor, and texture. It is something that a hungry man will eat and with which he will be satisfied. It is the job of the technician to produce foods which meet with these standards and at the same time to maintain, as far as possible, the vitamins, minerals, and other elements present in the raw products. To do this, he must operate at the highest possible speed, use the best known methods, and protect the product as well as he can with the packaging material available. No method of preservation will hold all of the desirable qualities of the fresh, raw product.

No matter how well the technologist does his job, there is no guarantee that vitamins, minerals, and other food elements will not be lost or wasted in the kitchens. In so far as the military uses are concerned, I hope, in fact I believe, that the cooks will be so instructed and supervised that the consumers will get all that is practically possible in the foods set before them. If it shall be found that the vitamin supplies are inadequate when dependence is placed upon the foods available, other methods of providing necessary vitamins are, and will be, available. It is our belief that properly prepared dehydrated foods will compare favorably with any others which might be available under the exigencies of military operations and possibly even with many of the so-called fresh products which are available to the housewife through the retail stores.

Losses of Vitamins Which May Occur during the Storage of Dehydrated Vegetables^{*†‡}

DONALD K. TRESSLER, PH.D., F.A.P.H.A., JAMES C. MOYER, PH.D., AND KATHERINE A. WHEELER

New York State Agricultural Experiment Station, Geneva, N. Y.

WHILE it is of great importance to produce dehydrated vegetables without marked loss of vitamins during preparation and dehydration, it is equally important to prevent considerable losses during the period between dehydration and consumption. During World War I millions of pounds of vegetables were dehydrated. When freshly dehydrated these products were palatable and possessed fair nutritive value, but, after being transported abroad, they were found to be markedly changed in palatability, odor, color, and vitamin content. In view of the fact that large quantities of vegetables are again being dehydrated for the use of our armies and our allies, it is of great importance to know whether or not these products will really retain their palatability and nutritive value during storage.

Since the last war, it has been found that both carotene and ascorbic acid are retained better in dehydrated vegetables if the enzymes of the vegetables are inactivated either by drying¹ at a sufficiently high temperature, or by

precooking² the vegetables prior to dehydration. Precooking (blanching) of vegetables to be frozen has also been found necessary in order to obtain retention of these vitamins during cold storage.^{3, 4} The U. S. Army specifications now require sufficient precooking of all vegetables (except onions) to inactivate peroxidase prior to dehydration.

The work reported in this paper was part of a study of the nutritive values of dehydrated vegetables carried out coöperatively with the U. S. Bureau of Home Economics, the New York State College of Home Economics, the University of California, and the University of Texas. The object of the particular study herein presented was to determine first what losses of carotene, thiamin, and ascorbic acid occur during the dehydration of cabbage, beets, rutabagas, and potatoes in a commercial plant in New York State, and second at what rate these vitamins may be lost during subsequent storage under various conditions.

ANALYTICAL METHODS

Moisture—Difficulties were encountered at the start with as simple a determination as moisture. Drying of the ground sample in a vacuum oven at 158° F. for 6 hours was soon found to be the only absolutely reliable method.

* *Journal Paper No. 526*, New York State Agricultural Experiment Station, Geneva, N. Y., September 23, 1942.

† The work reported in this paper was supported in part by the U. S. Bureau of Home Economics, Washington, D. C.

‡ Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

Carotene—The method described by Zimmerman, Tressler, and Maynard⁵ was employed.

Thiamin—The method of estimating thiamin used was the "Standard thiochrome assay for the determination of thiamin in cereal products" recommended by the Research Corporation Committee on the Thiochrome Method⁶ as modified by Moyer and Tressler.⁷

Ascorbic Acid in Cabbage, Rutabagas, and Potatoes—The Bessey and King⁸ procedure as modified by Mack and Tressler⁹ was employed.

Ascorbic Acid in Beets—The electro-metric titration method described by Kirk and Tressler¹⁰ was used.

The Preparation of the Dehydrated Vegetables

The vegetable samples studied were taken at various stages in the process of dehydration at the Dry-Pack Corporation plant at Lyons, N. Y. A brief description of raw vegetables and of the treatment given them during processing follows:

Danish Ballhead cabbage from Wayne County, N. Y., which had been stored for about a month, was trimmed of outer leaves, cored, and then shredded as for sauerkraut. Without further treatment it was spread on stainless steel trays and dehydrated for about 4 hours in a current of warm air in a cabinet drier. Rutabaga turnips from the Province of Ontario were washed, then peeled and diced. The product was blanched for 2 minutes in water near the boiling point and then cooled in water for 2 minutes. After draining, the diced turnips were spread on trays and dehydrated in the same manner as the cabbage.

Beets grown near Alton, N. Y., which had been stored for approximately 2 months, were thoroughly washed, then cooked in boiling water until almost done. The cooked beets

were peeled, trimmed, diced, and then spread on trays and dehydrated in the same manner as the cabbage.

Heavy Weight potatoes grown near Lyons, N. Y., which had been stored in a cellar for approximately 4 months, were washed, peeled in a potato peeler, again washed, shredded into small sticks of rectangular cross-section, which were blanched for approximately 2 minutes in water near the boiling point and then cooled with water in a rotating drum. The product was spread on trays and dehydrated as described for cabbage.

MOISTURE CONTENT OF THE DEHYDRATED VEGETABLES

The freshly dehydrated vegetables contained the following percentages of moisture:

	Per cent Moisture
Rutabagas	8.4
Beets	5.5
Cabbage	5.5
Potatoes	7.0

LOSSES OF VITAMINS DURING DEHYDRATION

The Danish Ballhead variety of cabbage is nearly white, except for the outer leaves which were discarded. Consequently, it was so low in carotene that the amount present was not determined. On a dry weight basis the fresh cabbage contained 5.92 μ g. thiamin per gm., and 4.40 mg. ascorbic acid per gm. After dehydration the amounts found were 5.60 μ g. thiamin and 3.56 mg. of ascorbic acid, indicating little loss of thiamin but approximately a 20 per cent loss of vitamin C.

The losses of carotene, thiamin, and ascorbic acid from rutabagas during preparation and dehydration are shown in Table 1. It will be noted that during blanching the losses of carotene, thiamin, and ascorbic acid were approximately 2, 17, and 22 per cent, re-

spectively. Dehydration itself caused little loss of carotene and thiamin. On the other hand, little ascorbic acid is left in the dehydrated turnip, 85 per cent being destroyed.

The beets were substantially cooked preparatory to dehydration. This caused a loss of approximately 16 per cent of the thiamin and about the same amount of ascorbic acid. Dicing and dehydration caused only a relatively small additional loss of thiamin and an additional 15 per cent loss of ascorbic acid (Table 2).

Potatoes* (Table 3) lost approximately one-third of their thiamin and 60 per cent of their ascorbic acid content during shredding and water blanching. No additional thiamin was lost during dehydration but the ascorbic acid content was nearly completely destroyed.

STORAGE STUDIES

Immediately upon receipt of each one of the samples of the dehydrated vegetables at the laboratory, it was packaged in three ways: (1) in tightly closed glass containers; (2) under carbon dioxide in tightly closed glass jars; (3) in either moisture-proof cellophane or pliofilm bags. One of each of these samples was stored at each of the following temperatures: -40° F., 33° F., 58° F., and 75° F. In the case of the samples held under carbon dioxide, the air was eliminated by slowly passing in carbon dioxide for 30 minutes through a tube reaching to the bottom of the jar.

The samples were analyzed monthly for ascorbic acid and quarterly for carotene and thiamin.

Regardless of the type of container or storage condition, none of the samples lost an appreciable amount of thiamin during the test periods of 3 or 4 months.

No one of the samples stored at -40° F. lost much carotene. At higher temperatures the loss was much more rapid (Figure 1). Storage under carbon dioxide reduced the loss of this vitamin; the advantages of storage under carbon dioxide were particularly noticeable at the highest temperature (75° F.).

No one of the samples of rutabagas (Table 4) or cabbage (Figure 2) lost much ascorbic acid during storage at -40° F. for 3 months. At higher tem-

FIGURE 1

ASCORBIC ACID CONTENT OF CABBAGE IN STORAGE

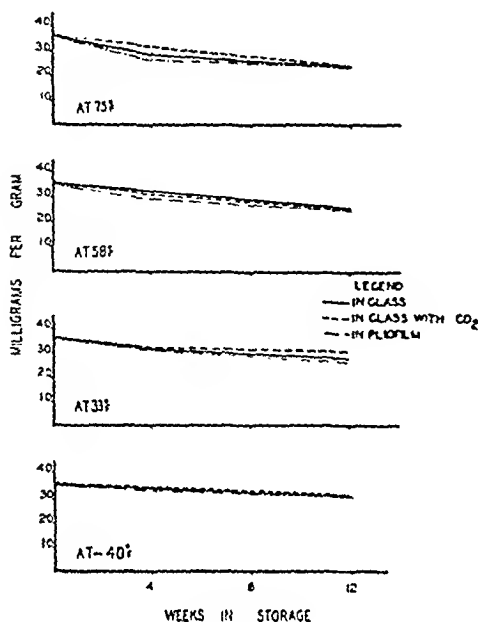

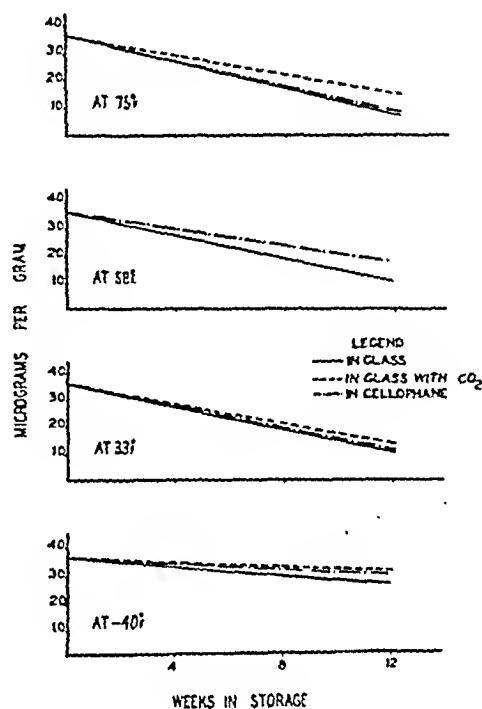

FIGURE 2

CAROTENE CONTENT OF RUTABAGAS IN STORAGE

peratures, there was a considerable loss from all of the samples of these vegetables. In general, the higher the temperature the more rapid the loss, although there are some apparent discrepancies owing to the difficulty of obtaining truly representative samples. Storage under carbon dioxide seemed to have little effect in retarding the

rate of loss of ascorbic acid from these vegetables.

It should be noted that these samples were relatively high in moisture. If dehydrated vegetables containing less moisture had been used, the rate of loss of carotene and ascorbic acid might have been lower.¹¹

	CO ₂	0.42	0.34	0.17

SUMMARY

The carotene, thiamin, and ascorbic acid contents of rutabagas, beets, cabbage and potatoes were followed during commercial dehydration and subsequent storage under controlled conditions. Prior to storage the dehydrated vegetables were packaged in three ways: (1) in glass containers, (2) under carbon dioxide in glass containers, (3) in either moisture-proof cellophane or plioilm bags. Storage temperatures employed were (1) -40° F., (2) 33° F., (3) 58° F., and (4) 75° F.

Little carotene was lost from any of the vegetables during dehydration but the loss of this vitamin was relatively rapid at all storage temperatures above -40° F. Storage under carbon dioxide helped to prevent rapid loss.

Some thiamin is dissolved out during hot water blanching. Subsequent storage caused no further loss.

Potatoes lost nearly all of their ascorbic acid content during blanching in hot water and subsequent dehydration.

The fresh beets contained a relatively small amount of ascorbic acid. About one-third of this was lost during pre-cooking and subsequent dehydration. The resultant product was not a good source of vitamin C.

Rutabagas lost approximately 85 per cent of their ascorbic acid during water blanching and dehydration. The remainder was fairly well retained at the lower storage temperatures but at

either 58° F. or 75° F. more than half is lost in 4 months. Storage under carbon dioxide had little effect in retarding the rate of loss during storage.

Cabbage retained its vitamin C content better than any other vegetable during dehydration and subsequent storage. That tested was high in vitamin C containing more than 3 mg. ascorbic acid per gm. of dehydrated cabbage.

Ultra-violet Irradiation as a Means of Disinfection of Air*

ALEXANDER HOLLAENDER, PH.D.

Senior Biophysicist, Division of Industrial Hygiene, National Institute of Health, Bethesda, Md.

THE bactericidal power of ultra-violet radiation has been known for many years. Careful studies on the wavelength dependence of this action of ultra-violet radiation established that the region of the spectrum in which waves are shorter than $3,000\text{\AA}$ is quite efficient in the killing of microorganisms, and that bacteria and fungi show their highest sensitivity around $2,600\text{\AA}$. Preliminary studies on the effect of wavelength $2,537\text{\AA}$ on certain animal viruses indicate that these viruses in a purified state have a sensitivity similar to bacteria at wavelength $2,537\text{\AA}$. The development of low pressure mercury vapor lamps with glass or quartz envelopes which emit about 80 per cent of their radiation at wavelength $2,537\text{\AA}$, very close to the maximum of highest bacterial sensitivity, has made available a ready and inexpensive means to be used for many practical purposes. This development coincided with the reawakening of interest in the control of air-borne contagion which was brought to the foreground in this country by W. F. Wells.

Although low pressure mercury vapor lamps have been used extensively in connection with air-borne microorganisms, it is only in the last three years that quantitative laboratory investiga-

tions on the efficiency of $2,537\text{\AA}$ radiation on air-borne bacteria, under carefully controlled conditions, have been conducted. After the early work of Wells, the papers by Koller, Sharp, Luckiesh, and Holladay, and Rentschler and Nagy, have helped considerably to clarify some of the problems in connection with the killing of microorganisms in air. These and other studies have also helped to focus our attention on some of the important contradictions which have appeared in this field.

Fundamentally, a bacterium should have equal sensitivity whether it is on an agar surface, in liquid suspension, or floating in the air. The killing should depend only on the amount of bactericidal energy absorbed; of course the biological history of the organisms should be the same in regard to media, age, and other biological factors. However, a number of investigators have found that there are differences in sensitivity when bacteria are irradiated in a dry, or when irradiated in a humid atmosphere. These may be due to a number of factors, some of which we will discuss.

METHOD OF SAMPLING

Experiments were conducted at the National Institute of Health with a number of different sampling devices, i.e., open plate method, the Wells centrifuge, and the Hollaender-DallaValle funnel device. These tests showed that,

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

depending on the humidity, dust content, and probably others factors, the different methods of sampling do not give necessarily parallel results. This appears reasonable if we follow the manner in which these devices remove bacteria from the atmosphere. The open plate method practically depends on gravity alone; the Wells centrifuge depends on moderate centrifugal force; and the funnel device emphasizes gravity through a strong impinging force.

There is very little doubt that similar factors which modify the sampling rate help also to modify probably the survival rate of the bacteria suspended in air when irradiated. This is, of course, very difficult to evaluate if we do not know the limitations of our sampling methods. It is urgently necessary to evaluate the different sampling devices and to establish the limitations of each.

CHANGE IN SENSITIVITY

Another factor which may contribute to the apparent variation of sensitivity in dry and humid atmospheres is the fact that bacteria which have survived exposure to ultra-violet radiation show less resistance to adverse conditions than normal bacteria, although this condition is more pronounced with bacteria irradiated with the very long ultra-violet. It may very well be possible that the dry atmosphere which is an unnatural medium for certain bacteria will enhance their ultra-violet sensitivity.

ADEQUATE IRRADIATION

The question of adequate irradiation of the air for the control of air-borne contagion has come up for consideration. It seems impossible at the present time to define quantitatively the radiation necessary to produce adequate disinfection. Several papers on this subject have appeared. The data in these reports are based on the lethal

effects of ultra-violet radiation on "clean" bacteria sprayed into the atmosphere. Such data are very useful since they give us the minimum intensity which should be supplied if the conditions are ideal. The Council on Physical Therapy of the American Medical Association states in its acceptance of ultra-violet lamps for disinfecting purposes that "obviously the manufacturer and distributor of such lamps must assume some responsibility for the adequacy of the lamp installation for purposes of radiant disinfection of the air, and for the adequacy of the protection from injury of the occupants of the space irradiated." This is certainly a reasonable point of view.

TYPE OF INSTALLATION

The methods used in the control of air-borne contagion are usually the following:

1. *Irradiation of the upper one-third of the room*—In this case the lamps are placed so that the light is reflected to the ceiling. A certain amount of the light is reflected or scattered back into the lower level, depending on the arrangement of the lamps and the type of paint used on the ceiling and walls. Only the upper one-third of the room will receive enough bactericidal radiation to kill microorganisms within a reasonable time. One usually depends on natural circulation in the room or uses forced circulation to bring as often as possible all the air in the room to the bactericidal radiation. If the ceiling is high this may give quite an effective arrangement. Some of the most successful installations use this technic.

2. *The ultra-violet screen method*—This mode of control of air-borne contagion is used most extensively in hospitals. It is often installed across corridors or cubicles to control the circulation of bacteria. Successful installations for the control of air-borne contagion have been reported from

children's hospitals where such screens have been placed at the entrance of each cubicle. If the ultra-violet screens are used in hospital corridors across the passage from one part of the building to another, this method appears less promising. To kill organisms in the air passing through the screen, or especially on the clothing of nurses and physicians, the radiation would have to be so intense as to make it quite dangerous for persons to pass through such screens.

Another type of screen has been suggested which practically would surround the bed of each patient with ultra-violet curtains, or place ultra-violet curtains in the aisles between school benches. Such installations would appear to me to be rather dangerous to use since inadvertent exposures of exceedingly dangerous character could not be avoided.

3. *Irradiation of air in air ducts or in plenum*—In this type of installation, ultra-violet sources are located inside the air ducts or the plenum. Often the inside of the walls of the ducts are covered with ultra-violet reflecting paints in an effort to make best use of the radiation. Considerable work has been done in designing and testing such installations by a number of commercial laboratories. However, no actual epidemiological data seem to have been published on the reduction of air-borne infections in buildings with such equipment. It would appear that such installations are of considerable promise, especially in air-conditioned buildings, since they would avoid the exposure of the occupants to ultra-violet radiation.

PRECAUTIONS

The greatest danger involved in the use of bactericidal (2,537Å) radiation is the possibility of over-exposure. Very little is known about the effect of 2,537Å radiation on the eyes and skin

of the occupants of the rooms. Most manufacturers supply some warning in regard to the use of these lamps. But in regard to some of the installations, we have observed that too little or no warning was given in regard to the dangers involved in extensive exposures of 2,537Å radiation. Time and again reports have appeared that workers in operating rooms, and other places equipped with 2,537Å lamps, have been adversely affected by this radiation. It also should be mentioned that many of the effects of ultra-violet appear not earlier than several hours after exposure.

Another point which should be emphasized is the production of ozone by these lamps. There seems to be no danger connected with this if the ventilation is good. However, if the air becomes stagnant and the lamps continue to burn, the concentration of ozone may reach toxic levels. Since there is very little information available on the toxic limits, or on methods of determining these limits, it would be very well if research on these problems were encouraged.

SCHOOLS

An outstanding study on the use of ultra-violet radiation in the control of air-borne contagion in schools has been described by Wells, Wells, and Wilder. Using similar installations, rooms in the Germantown Friends School and the Swarthmore Public School were equipped with low-pressure mercury-vapor lamps. These lamps irradiated the upper one-third to two-fifths of the school rooms, the radiation being reflected toward the ceiling. Only relatively little radiation comes to the level of the benches in these rooms. It would have been helpful had actual measurements been given.

These tests were conducted over a 4 year period at the Germantown School and for a 1 year period at the Swarth-

more School. Considerable decrease in mumps morbidity was noted in the irradiated rooms at the Germantown School. In both schools the incidence of measles in the irradiated rooms was considerably lower than in the rest of the schools during the 1941 measles epidemic.

As mentioned in the beginning of this discussion, more data are desirable in regard to the physical setup, intensity of radiation sources, and the effect on the children and teachers of the scattered ultra-violet and the peculiar blue light given by these lamps. Also, a survey of the natural bacterial population in control and irradiated rooms would have helped to understand these striking results.

HOSPITAL INSTALLATIONS

The danger of cross-infection which is always present even in the best conducted hospitals has made them a good proving ground for the usefulness of ultra-violet radiation in controlling air-borne contagion. Especially is this the case in children's hospitals. Many of the findings of recent experiences in this field are discussed in the volume *Aerobiology*. Good results were obtained at the Hospital for Sick Children in Toronto where respiratory infection was reduced from 40 per cent in the control rooms to 10 per cent in rooms irradiated with ultra-violet. Less convincing results were obtained at the Infants' Hospital in Boston using ultra-violet screens across the entrance to the cubicles. At the Home of Hebrew Infants in New York, the method of irradiating the upper one-third of the room was used to control air-borne contagion, and it was found that infection could be reduced by 50 per cent in rooms irradiated with ultra-violet. At the Cradle in Evanston the screen method of ultra-violet irradiation compared very well with mechanical barriers in the control of air-borne

contagion from cubicle to cubicle. The article by Stokes and Henle on "Prevention of Epidemic Influenza," with a discussion of the usefulness of ultra-violet light in control of this virus disease is of interest. According to these writers, ultra-violet light compared very well with propylene glycol Aerosol.

Against these positive results there are very few negative reports. In none of the publications has mention been made of how much radiation the exposed persons have actually received. The Council of Physical Therapy of the American Medical Association has, in its acceptance of germicidal lamps for disinfecting purposes, given a very definite value of 5 ergs/cm²/sec. for 8 hours exposure and 1 erg/cm²/sec. for 24 hours exposure. Have these limits been kept in these installations? It is requisite that publications on this subject give data on the actual intensities used for disinfection of the air and the quantity of ultra-violet radiation to which the occupants are exposed.

The use of ultra-violet radiation in the control of air-borne microorganisms in operating rooms has been introduced by Hart. He reports that ultra-violet radiation (2,537Å) offers the simplest and most effective means of controlling air-borne wound infection. He especially emphasizes the protection of the personnel against over-exposure.

There are several investigations in progress on the usefulness of ultra-violet radiation in the control of air-borne contagion in crowded quarters. Since it usually takes several years to obtain reliable data in such investigations, it would be premature to discuss them.

There have also been reports upon the use of ultra-violet radiation in controlling bacteria and fungi in meat packing plants, instrument cabinets, etc. Most of these matters are still in a controversial stage.

CONCLUSIONS

We have in ultra-violet (2,537Å) radiation a highly effective tool for the killing of microorganisms. Since other living cells do not differ fundamentally from bacteria in their sensitivity, this radiation will affect other cells in about the same way it affects microorganisms. It will either kill them or damage them, modify them temporarily or change them permanently (genetically). It is essential that we become conscious of the danger of ultra-violet radiation if used carelessly. The practical application of light of wavelength, 2,537Å will do no harm if fundamental precautions are taken to protect the uninformed person. The Council of Physical Therapy of the American Medical Association has given recommendations in connection with the acceptance of these lamps. In a review of the literature I find that little reference is made to the precautions suggested in this "acceptance," although not enough time has elapsed since its publication.

Among the problems in connection with ultra-violet radiation which need further laboratory study and clarification, are the following:

1. Reevaluation of the sampling methods for air-borne organisms now in use, to establish their limitations and shortcomings, especially in regard to humidity, dust, etc., in an effort to improve them.

2. Requirements in regard to installation of 2,537Å lamps, especially with regard to

those designed for the protection of the people exposed.

3. Evidence submitted in regard to the usefulness of ultra-violet radiation in control of air-borne contagion.

Health Education in a Medium Urban Community*

EARLE G. BROWN, M.D., F.A.P.H.A.

Commissioner, Nassau County Department of Health, Mincola, N. Y.

HEALTH education is a tool, like sanitation, immunization, law enforcement, or medical care. It is a medium through which health agencies attempt to prevent disease, lower the death rate, and increase the physical and mental vigor of the people they serve.

Mustard says that health education "is that process or those procedures through which, directly or indirectly, individuals who make up the public or a particular segment of the public are brought to a performance of those things believed to be beneficial to health, and to an abstinence from those things believed to be injurious to health."¹

A successful public health program demands and receives the support of the people who benefit from it. Some departments of health have achieved outstanding success in all fields; other departments have attacked and conquered particular problems, one at a time, while conducting a general program.

Success or failure of a particular program depends upon the knowledge which the people have of its general objectives. The laity must know the potential resources for health in order

to take an intelligent part in its acquisition and development. Furthermore, the desire for health implies the willingness to share in efforts to obtain it and to participate in the creation of individual and common resources for its protection and advancement in quality and quantity. To this end, the relevant facts of human life, the natural history of preventable diseases, of remediable and preventable defects, and the causes of premature death, as well as the record of progress for extension of the span of life must be widely understood, not only among public health workers but among the laity as well.

Building today upon the work of pioneers such as Sir Edwin Chadwick, Dr. John Snow, Hiram F. Mills, George W. Fuller, Earle B. Phelps among the sanitarians, and Koch, Pasteur, Stephen Smith, William H. Park, Theobald Smith among the bacteriologists and physicians, public health workers have reared a structure which has definite form and purpose and in which there is balance between the control of the environment and the promotion of individual hygiene.

The problem of the local health administrator is to build a well balanced and coördinated system of health service. The job cannot be done by the administrator himself; he may be ever so able a leader but, without the proper working tools, he can accomplish little. What then are these working tools? In

* Presented at a Joint Session of the American School Health Association and the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

my opinion the most important instrument for achieving success is personnel. By "personnel" is not meant mere office holders, but employees with adequate technical training and proven ability for the specific duties assigned to them. In other words, a local health department cannot be expected to accomplish a herculean task without securing the ablest talent the market affords.

The principles of organization and service in public health are the same regardless of whether the department serves a few thousand or several hundred thousand people. The health department which serves a county of 30,000 population will have a health officer and necessary nursing, inspection, and clerical personnel.

A properly organized local department of health serving a medium urban community will usually have essential bureaus or divisions manned by specialists in their particular fields. The health officer in conjunction with the chiefs of divisions should formulate the general policies, outline qualifications of personnel to be employed, indicate essential items in the program, and prepare the necessary manual of operation to be used in the promotion of public health. The general program should be submitted to the members of the board of health for their information and, if necessary, for their approval; in turn, it should reach the state health officer for his approval.

Since the local department of health is a definite entity and functions as such, monthly reports should be submitted to the state health department; these reports contain a summation of activities and accomplishments of the personnel. Special reports may also be submitted. These reports constitute a part of the material upon which the state department of health bases its work in education and they serve the local health department similarly as

basic information for its educational work.

No longer can those who are interested in public health work entirely satisfy their communities or the art and science of preventive medicine through the traditional programs to control infectious diseases, to detect physical defects of school children, or to teach the health rules of nutrition, rest, and physical recreation. Health departments must serve as a potent influence to keep individual and community health operating at their highest level.

Nassau County, N. Y., is offered as an example of a medium urban community where what is hoped will be an effective health program is in its early stages. Nassau County is on Long Island, its western boundary line adjoining New York City, extending from Long Island Sound on the north to the Atlantic Ocean on the south, a distance of 23 miles. The county is 16 miles wide from the New York City boundary line on the west to Suffolk County, on the east. It has a land area of 274.9 square miles.

The county seat is located at Mineola, in the approximate center of the county; component parts include 2 cities; 63 incorporated villages, and 3 townships. The population in 1900 was 55,689; in 1920 it was 126,120, and increased to 406,748 in 1940. Due to a marked increase in war industry it is believed the population now exceeds 450,000.

The county operates under the County Government Law of Nassau County, otherwise known as the Nassau County Charter. Prior to January 1, 1938, each city, incorporated village, and township had its own board of health and part-time health officer, a total of 68 uncoordinated health jurisdictions. These municipalities had, in addition, 11 public health nurses, 10 inspectors, and 7 stenographers and

clerks. The Public Health Committee supported by county tax funds had 6 public health nurses and attempted to carry on a county-wide service; due to limited personnel, major emphasis was placed on clinic and follow-up service.

In accordance with the provisions of Chapter IX of the Charter, Nassau County became a county health district, local boards of health were abolished and their powers and duties were transferred to the county department of health. A single board of health composed of 5 members appoints the commissioner who is the administrative head of the department and serves for a 6 year term. The Charter also transferred local health department employees to the county health department together with 37 part-time health officers who became deputies of the commissioner, serving until the respective terms expired for which they had been appointed. The last of such part-time deputies completed his term about 1½ years ago. Appointments of personnel since the inception of the department, other than the commissioner and deputy commissioner, have been subject to requirements of the Nassau County Civil Service Commission.²

Nassau County is in the New York City district of the New York State Department of Health and the services of the District Health Officer are continuously available for guidance and assistance. Since the county department of health has met all requirements of the State Department of Health, its expenditures are annually reimbursed in the amount of 50 per cent.

The department program is administered through 5 divisions, namely: Communicable Diseases, Sanitation, Public Health Nursing, Maternal and Child Health, and Statistics and Records. The department does not have a division of health education; this activity is directed by the commissioner.

Usual and accepted methods of

health education were inaugurated when the department was organized in 1938; their expansion has paralleled that of the department.

Numerous less tangible but nevertheless important media of health education are inherent in health department organization. The degree to which they may be recognized as contributing to health education is dependent upon the quality and extent to which they are employed.

The epidemiologist has an excellent opportunity to give information to the public during his investigations, and also to render medical advisory assistance to the public health nurse and the sanitarian.

Public health physicians engaged in the administration of various services such as venereal disease, tuberculosis, and maternal and child health, act as a guide to both the medical and nursing professions as well as in the formulation of disease control and health education programs.

Among the various media, perhaps the most productive is the informal instruction given by the public health nurse through personal visits and group conferences. This statement is made with full appreciation of previously reported studies which have challenged the educational value of the nursing visit and is based upon two concrete factors: (1) the department policy of providing in-service training and experience for the staff nurse in each special field before full responsibility for instruction in that field is placed upon her, and (2) quick returns from nursing visits denoted by action on the part of those visited.

After 4½ years the department's nursing service is now generalized; complete generalization, however, was reached only as in-service training could be provided in the various services.

Prior to the transfer of tuberculosis

nursing service in 1939 from the Nassau County Sanatorium to the department of health a series of 17 carefully planned lectures on diagnosis, treatment, and control of the disease was given to the nurses by the superintendent of the sanatorium. These lectures were followed by a physical examination of each nurse in the outpatient clinic and a period for observation, including participation in the sanatorium program. Case summaries were prepared by the nurse formerly responsible for tuberculosis nursing; she then, in the capacity of consultant, gradually turned over the case load and assisted both supervisors and staff nurses alike in assuming full responsibility. Since the staggering case load formerly attempted by two nurses was spread among 33 nurses, results were immediate. Since that time, clinic attendance has continued to improve, many lost cases have been brought to light and new cases found.

A similar plan of training for the nursing staff was followed before the cancer nursing service was absorbed. The medical consultant of the Tumor Clinic assumed responsibility for a series of 19 lectures, for which he secured some of the best specialists in the county and in the metropolitan area. These lectures covered the general aspects of the problem, symptoms, diagnosis, surgery and the use of x-ray and radium. The last four lectures were on the general topic of "Cancer and the Community." The practical experience program included 8 days of planned observation and practice, the nurse being given an opportunity to become acquainted with tumor patients from her own district. Gradual transfer of the case load to the department of health by the Cancer Committee nurse was accomplished by use of a case summary sheet. Each case was discussed with the public health nurse by the nurse employed by the Cancer

Committee, the latter thus becoming a consultant in cancer nursing.³

In further preparation for the maternity nursing service a course of 20 weekly 2 hour lectures and demonstrations in obstetrical nursing was arranged with Maternity Center Association of New York City. All members of the field nursing staff enrolled in and completed this special course, following which there was an immediate increase in standards and services in maternity nursing.

It is reasonable to expect a relatively high quality of instruction as a result of exposure to experiences provided through this particular pattern of staff education which included: (1) theoretical instruction regarding the scientific facts concerning the disease or condition; (2) observation of diagnostic, treatment, and control methods in special centers for care; (3) participation in the special center program to gain a complete understanding of all aspects of the disease or condition, and (4) immediate field experience under close supervision. This pattern followed in improving the quality of the various services mentioned is now in progress in orthopedics.

Other factors which influence the quality of instruction given by the public health nurse also include: (1) regular staff conferences, (2) participation in the student program, and (3) individual study program.

The three point staff conference program plan includes: (1) interpretation of new policies; (2) free discussion and group problem solving, and (3) formal presentation of current research, book reviews or other pertinent contributions in the health and medical fields. Formal presentations are arranged by a staff committee and may include discussions by some member of the group, by administrative personnel of the department of health, or by some individual outside the department of health

who has especial qualifications to make a contribution which will further enrich the background of the field nurse.

The department is fortunate in being recognized as a center for field experience for graduate students in public health nursing. The responsibility for interpreting field service to these advanced students is a constant stimulant to improve the teaching content of visits. The informal interchange of experience also offers an opportunity for further enrichment.

In the individual study program it is significant to note that during the past 4½ years, a staff increasing from 17 to 35 nurses, has through self-directed study taken 182 courses (for which they paid \$3,788), involving 6,122 hours of their personal time, exclusive of travel and study. Five nurses have had extended periods of study, one completing degree requirements.

These means of improving the contribution of the public health nurse to the community health education programs have also been extended to nurses in all nonofficial agencies.

Because all members of the nursing staff are qualified civil service employees, have been given in-service training in special services, carry out a planned program of individual study, keep up-to-date through staff conferences, and receive individual help through supervision on the job, each nurse in her own right is actually a health educator and carries an effective health message into each home or place she visits.

Last year the nursing staff made approximately 35,000 visits. Although many of these were revisits, this represented the direct exposure of 48,600 Nassau County residents to some phase of health instruction but an unknown number of indirect contacts, and exclusive of the number attending clinics. Based upon the preparation of the nurse for her work and the apparent

response of individuals to her visits, it is justifiable to recognize this volume of work as a distinct contribution to the community health education program.

A second medium of public health education is available through personnel dealing with sanitation, although to a lesser extent. The educational and police work of this group involves contact with a wide variety of problems and people. The limitations on the effectiveness of health education through this personnel is occasionally due to deficiencies of educational and technical training in the individual, which will of course be overcome in time as qualified personnel replace inherited and unqualified appointees.

Upon the formal establishment of the department's Division of Sanitation, a course of in-service training was instituted and carried on over a period of a year under the supervision of the director. This instruction served to acquaint the personnel with technics of their own duties and gave them a broader picture of public health work in general. This first course amounted to 100 hours of instructions and supervised field experience.

Subsequently those of the inspection staff who had adequate educational background completed a university course in food sanitation. Food inspection personnel have also participated in short courses given through the State Education Department and are regular attendants at conferences of food officials in the metropolitan area.

These representatives of the health department have in turn become better able to accomplish their objectives in the field which are basically educational and satisfying to the citizens contacted to the extent that they meet a need for service and information.

The extent of the type of this contact with the public is indicated by the more than 32,000 inspections and field

visits during 1941. The actual number of residents reached by this service is considerably greater than the number of inspections.

Exigencies of the war have brought group instruction to the front as a means of community health education to an extent heretofore unparalleled. The past year has afforded an opportunity to reach persons in all strata of society displaying an eagerness to learn. Organized groups of influential and economically independent citizens have invited department representatives to teach them facts regarding community health services and their utilization, as well as other factors that will contribute to healthful living. The administrative staff has become part of a county faculty which is constantly called upon to lecture to various groups in training for defense activities. During the past 9 months this service has included a total of 51 lectures.

In addition, staff nurses have taught 325 home nursing class sessions, 294 mother's class sessions, and 43 classes in first aid; total attendance for these 662 class sessions was 7,641 persons.

During the past summer a plan of group instruction was inaugurated among workers in defense schools and industries. To date, 32 sessions have had an attendance of 2,274 men and women. Instruction to industrial workers is planned in units of four lectures upon: personal health, community health, nutrition, and child care.

Through nursing and sanitation personnel and also including visits by epidemiologists and other department physicians it is believed that about one-fourth of the total population of Nassau County had some personal awareness of the department of health and its relation to their own health and well-being during the year 1941. This does not include but is supplemented by the dissemination of health information by other means previously referred to.

A third medium, that of department representation on a variety of community advisory boards and committees, provides opportunity for effectively reaching an influential group of citizens occupying key positions in bringing about changes in community thinking and action.

Administrative personnel of the department have continuously participated in the activities of such county organizations as the Nassau County Medical Society, The Nassau County Tuberculosis and Public Health Association, the Nassau County Cancer Committee, Nassau County Central Index, Nassau County School Health Council, Nassau County Public Health Nursing Council, Nassau County Chapter of the American Red Cross, Nassau County Nutrition Council, the Nassau-Suffolk Conference of Waterworks Superintendents, Long Island Section of the New York State Sewage Works Association, and public official groups such as building and zoning officials. More recently these activities have been extended and are included in connection with the Office of Civilian Protection of the Nassau County War Council.

Participation of this type not only affords face to face opportunities for health education but ties in the resources for these social and philanthropic organizations to the total community program.

SUMMARY

1. Nassau County is an urban community consisting of both thickly and sparsely settled communities and having a total population of about 450,000 persons.

2. Considering Nassau County as a medium urban community, the health education program is reviewed on the basis of 4½ years' work by a single county department of health.

3. Usual and accepted procedures in health education were adopted and have been used since the department was organized in March, 1938. In addition, certain routine functions of the department are considered from the standpoint of their relationship to health edu-

cation, particularly in the fields of epidemiology, nursing, and sanitation.

4. The effectiveness of these aids is dependent upon individual abilities based on prior education and in-service training and their spirit and attitude in personal contacts with the general population and various organizations.

5. The accomplishments of field personnel in health education are in turn dependent upon the stimulus of capable administrators.

6. The quality of health department service governs the extent to which other community agencies accept direction and participate in the organized health education program.

SIR ARTHUR NEWSHOLME, K.C.B., M.D. (LOND.), F.R.C.P.

INFORMATION that Sir Arthur Newsholme had died was somewhat delayed in reaching the United States, but this does not dull the sense of loss which will be felt by those who knew him or knew of him. His acquaintanceship in the United States and Canada was wide, and his prestige rested upon a fine foundation of professional accomplishment and personal graciousness. It should be recorded that we, in America, regarded him as a great man; and for our American annals we can do no better than to re-publish the obituary notice that appeared in the *Lancet* of May 29, 1943, which is as follows:

"The death of Sir Arthur Newsholme on May 17 at the age of 86 removes a landmark in our national system of public health of which he was both the reformer and the chronicler. During those eleven crowded years in Whitehall when he was medical officer to the Local Government Board, before its absorption in the Ministry of Health, the emphasis shifted from sanitation to personal hygiene. He had a vision of human lives emancipated by their own effort and he set his course to provide the conditions of healthy living.

"Arthur Newsholme was born at Haworth, and his memories went back to the 'sixties and talks with people who had known the Brontes in that West Riding town. His mother was early left a widow and he won his way through school and college with the help of scholarships. After a year as apprentice to a Bradford practitioner he entered St. Thomas's Hospital at a time when surgery was coming to life in the carbolic spray, and where he listened to Sir John Simon's last lecture. Qualifying LSA in 1879 he was house-surgeon there and held other resident posts while he was taking the London MB with several honours and the gold medal in medicine, followed by similar distinctions at the MD examination. In 1883 he was appointed part-time MOH for Clapham where he had already been in successful general practice for two years, and in 1888 after taking the certificate in public health he became the first full-time MOH for Brighton (which had just been made a county borough) at a salary of 750 pounds. Here he spent the next twenty years, and his determination to get his principles of public health established in practice, based as it was on his own experience as family

doctor, soon won recognition. It was in Brighton in the year 1899 that the notification of tuberculosis (on a voluntary basis) began in this country and it was here too that serious research started into the aetiology of rheumatic fever, of diphtheria and of summer diarrhea. His demonstration that shellfish may convey typhoid brought him into conflict with interested parties. In the background were numerous mathematical excursions, following up his guide-book (*Elements of Vital Statistics*, 1889) and elaborating the 'fallacies of observation' and the 'fallacies of inference' on the avoidance of which his mind was keenly set. At the conclusion of this period the municipal council testified on vellum to 'the unstinted service by reason of which a continuous and progressive decline in the death-rate has been brought about.'

"His translation, in 1909, to the Local Government Board came about through the wisdom and on the personal decision of John Burns, a kindred spirit in many ways. With years of experience as MOH he was in a unique position to reconcile methods of local and central administration. Steadily, though not without heat and effort, Newsholme overcame the difficulties of an outsider entering the closed ring of Civil Service and piloted the expansion of our public health administration from a predominantly environmental service to a personal service of preventive medicine. On his initiative the anti-tuberculosis and maternity and child welfare activities developed from isolated local efforts to national schemes. In 1916, on the appearance of the report of the Royal Commission on Venereal Disease, he secured the prompt adoption of nearly all its recommendations. And these were only some of the directions in which his single-minded and virile will broke down resistance and implemented wise reforms. The position of independence in which medical officers of health now find themselves, and the resulting advance in public appreciation of health services, is due in large measure to his enthusiasm and example.

"Retirement from Whitehall in 1919 was not the end of his work but the beginning of a new phase. Invited by W. H. Welch to lead the new school of hygiene at Johns Hopkins he had a profound influence on American public health through professional and personal contacts with a new generation of public health officers. His American experience, his familiarity with our own system, and his visits on behalf of the Milbank Fund to European countries and especially to Russia (c.f. *Red Medicine* with J. A. Kingsbury, 1933) found expression in a series of 'International Studies on the Relation between the Private and Official Practice of Medicine,' written with the terse lucidity characteristic of all his reports. This experience and much else is embodied in two autobiographical volumes, *Fifty Years in Public Health* (1935), and *The Last Thirty Years in Public Health* (1936). His worth as an administrator was recognized by honours and responsibilities. He was made CB in 1912 and promoted KCB in 1917. He was president of the Society of MOHs. He sat as crown nominee on the General Medical Council from 1910 to 1919. He examined for the Universities of Oxford, Cambridge and London, and he was a member of the executive of the Imperial Cancer Research Fund.

"Of the manner of man behind this achievement a few words remain to be said. During the years of struggle when he was fighting against obstruction and inertia his critical mind and caustic tongue were sometimes more evident than his generous heart, though generosity of temper and of purse was always near the surface. He had the Yorkshireman's canny delight in a good bargain, as well as some of his bias towards the material side of human welfare. His last ten

years were clouded by the loss of his wife after fifty years of close companionship. But he had his library and his garden, and in his determined maintenance of interest in his fellows he triumphed over bereavement. The Worthington Council of Social Service had won his warm support. During this time too he made many new friends who could testify to unobtrusive acts of kindness, to his invincible cheerfulness, to his alertness of mind, and above all to the transparent goodness which was manifest in him."

STUDENT WAR NURSING RESERVE

LAST October we got a little wrought up over the need for nurses and wrote an editorial about it. The editorial was not released for we were told by colleagues that the situation was very delicate, that brains much better than the Editor's were at work on the subject, and that the then current plans were of the nature of a military secret.

Since that time the typescript of the editorial in question has remained in the Editor's gestation barrel. In the light of recent events, however, it is now brought forward as a springboard for further observations. This is it:

"Thoughtful persons, both professional and lay, are becoming increasingly concerned with the nursing situation. Only the most optimistic can foresee, for the future, a supply of nurses sufficient to meet military and civilian needs. Those in the nursing field have attempted in various ways to solve the problem but the outlook remains disquieting. Because of limitations in numbers, in training, and in availability after training, the Red Cross Nurses Aids, recruited essentially from women of leisure, cannot meet the demands. Federal subsidies made to nursing schools, in order to permit them to take a larger number of students, have helped to some extent but not enough. Publicity and various local efforts to persuade young women to enter nursing schools have been only partially successful and there still remains as a bleak outlook a probable shortage of nursing care before the war comes to a close.

"This lack of success inclines one to wonder if possibly nursing is still cruising on the fat white ocean-liner of peace rather than driving forward on the lean ship-of-war. Today, the recruiting of man and woman power is highly competitive, and success appears to depend upon how completely the opportunities offered meet the psychological demands and the income necessities of those to whom the appeal is directed. There seems no likelihood that the WAACS and the WAVES will be unable, in spite of high standards, to fill their ranks with ease. And why? Because they offer to young women the opportunity of entering immediately into a service which is recognized as an integral part of the military effort. They pay her while she is being trained, and most of all they put her into a snappy, and official military uniform, which indicates to relatives, friends, acquaintances, and photographers that she belongs; that she occupies a glamorous place in the national war effort. As against this, the recruitment of students for nursing schools stands not much chance. It is essentially on the negative side. The high school graduate and young college-woman is approached on the basis of local hospital needs, or at least largely in terms of civilian needs. She is asked to undertake a course of training of nearly three years, during which time she sinks into anonymity so far as the war is concerned, and, except for her

board and keep, is expected to do this for nothing, which frequently she cannot afford to do.

"In the circumstances, might it not be well to consider making the appeal for student nurses on a realistic basis. Might it not be worth while, over and above routine recruitment for local needs, to consider the establishment of a WA—Corps for student nurses enrolled for future service with the Army or Navy. If such a corps were established, put in an off duty, official military uniform designed by a topflight coutourier, if that corps were disciplined to an alert esprit, detailed to regular nursing schools for training, paid as other students undergoing military training are paid—if these things were done and supported with national publicity, it is quite possible that the whole picture would change overnight. Another possibility to be considered, too, in spite of the fact that it will strike horror into the hearts of some of the leaders of nursing, is that perhaps in addition to commissioned nurses, there should evolve for military purposes a new type of Nurse's Aide, to become, possibly, sergeants in the nurse corps, *Military Nurses*, who conceivably could be given nurse's training rather than nurse's education, and who might complete such training in a time much shorter than that now required for the graduate nurse."

The Bolton-Bailey Act recently passed by Congress provides many of the elements recommended above. A Student War Nursing Reserve is set up in the Public Health Service (it is unfortunate that the initials do not spell anything); a uniform is to be provided and the student will be paid a stipend. It is on the latter point that we are apprehensive. According to an announcement in the June 11 issue of the *Public Health Reports*, this stipend will begin around \$15 a month and terminate at an amount not less than \$30 a month. It is difficult to understand why it must be so low. There seems to be nothing in the Constitution of the United States that makes it illegal to pay student nurses on a basis equal to that paid other students in training for war work. In medicine there are many applicants for each opening in a medical school and the student-soldier gets room and board and \$50 a month. In nursing where the number of applicants is alarmingly scant, it is not likely that \$15 to \$30 a month will stand up against the competition of business and industry or the intriguing military services which young women have a chance to enter. The mere fact that the United States of America sets such a low rate of pay for the student War Nursing Reserve is more than likely to cause young women to regard it as correspondingly less important than the other services.

And now, one final word to the Surgeon General: Dr. Parran, you watch your step about that uniform! If this matter were male and epidemiological, suggestions would be superfluous. But it is neither of those things. On the contrary, it is so female that it is ethereal—an ethereal salt of glycerol, the principal ingredient of dynamite. In handling this stuff you will need advice, and how you will need it. The consultant you want, however, is not in your Service, has no honorary degrees. The address is Fifth Avenue.

LETTER TO THE EDITOR

ALTHOUGH the discussion of H. M. C. Luykx' letter which appeared in the April issue of the JOURNAL aroused a good deal of interest, it was not planned to publish any further comments on the subject. However, on receipt of the communication presented below, the Editor changed his mind, for the point which Dr. Lumsden makes is of the nature of a basic principle, and to the general effect that a biostatistical chain is no stronger than its weakest epidemiological link.

TO THE EDITOR:

The outbreak of letters to the Editor appearing in the April and May (1943) issues of the JOURNAL regarding the application of statistical technics or methodology to some figures in an article on The Incubation Period in Epidemic Poliomyelitis, by Dr. Albert E. Casey, in the *J.A.M.A.* (120, 11: 805) of November 14, 1942, seems to warrant a letter to the Editor on the practical aspect of the basic matter.

To working epidemiologists and others in public health practice it is of no practical importance whether the \pm or standard deviation or probable error in the mean or average incubation period, as calculated by Dr. Casey apparently on a speculative or at most a hypothetical basis, was 1.6 or 1.1 or more or less or whatever, if any. Dr. Casey does not know, and the means were not and are not at hand to determine, whether there were any truly secondary cases in the series. As is indicated by Dr. Casey in the first paragraph of his article, we do not know the mode or modes of spread of poliomyelitis infection. A later case among contacts of an earlier case does not mean necessarily that the infection has passed from the one to the other. It is barely possible that figuring incubation periods of poliomyelitis on a basis of exposure through personal contact is as erroneous as it would be to figure that of bubonic plague, malaria, or yellow fever on a similar basis. In intensive outbreaks in limited areas many strict coincidences having no real

bearing on the causation of the disease may be found and be built up into elaborate and, unfortunately, misleading hypotheses or even doctrines, by single-minded investigators.

To some of the observers, including myself, the most striking epidemiological feature of the outbreak of poliomyelitis occurring in Walker County, Ala., between the last part of June and the last of September, 1941, and reported by Dr. Casey, was the geographical distribution. A description of this feature has not yet appeared in the literature. In general, it was somewhat as follows:

Of the 130 cases reported in the county, with a population of about 65,000, over 80 per cent were in the southeast quarter of the county's area. The population of this quarter was about 18,000. Thus the incidence was over ten times as high in this quarter as that in the other three quarters of the county's area. In the southeast quarter the disease was concentrated and prevailed at a very high rate in the low-level river-valley areas of the towns of Cordova and Dora. The hill sections of these towns, comprising about one-third of the population of Cordova and two-thirds of that of Dora, remained exempt from the outbreak.

Poliomyelitis virus was reported (by Dr. John R. Paul and his coworkers) to have been recovered from flies captured in an insanitary privy in the heavily affected section of Cordova. The whole area of high or outbreak incidence in Walker County was within

ready range of fly-flight, bird-flight and rat-travel from Cordova or Dora. Along with the number of diagnosed and reported cases there should have been, according to the contentions of the "contagionists," a very much larger number of clinically undiagnosable but potentially infective abortive cases and carriers.

In view of the uncertainties as to the immediate sources of the infection in the situation, the undertaking to figure the average incubation period from the

recorded histories of personal contact between diagnosed cases appears adventurous; and the statistical discussion of the figuring, though interesting and in a way illuminating, seems of only academic importance.

L. L. LUMSDEN,
Medical Director (Ret.),
U. S. Public Health Service,
Lecturer in Epidemiology,
University of Texas
Medical School

JOURNALS WANTED

Readers are asked to address spare copies of the January, 1942, and March, 1943, issues of the *American Journal of Public Health* to the offices of the Association, where they will be most welcome.

Proposed Report on the Educational Qualifications of Health Educators*

I. THE GENERAL SCOPE OF HEALTH EDUCATION

The health educator assists in helping people to become intelligently aware of individual and community health problems and to share the responsibility for their solution. He interprets health needs, desirable health behavior, and the services of professional health agencies. Successful health education can rarely be accomplished by the use of publicity technics alone. It almost always includes the development of satisfactory learning experiences within organized groups and the training of other public health personnel to aid them in improving the educational opportunities presented by their contacts with individuals.

Health education is rapidly becoming recognized as one of the important fields of service in the modern public health movement. The emphasis upon health education and the demand for professionally trained health educators are increasing. We are without accurate data on the number of health educators now employed in the United States. It is estimated that there are probably four hundred to five hundred, exclusive of teachers of health in public schools and institutions of higher learning. Increasing consideration is being given to the organization of unified, community-

wide programs. Thus, promotional progress may be anticipated by the beginning health educator, both through the expansion of his program and through transfer to the service of larger population groups, as his ability is demonstrated.

The health educator in the health department works under the administrative leadership and direction of the health officer. The health educator working in the school system as a teacher, supervisor, or consultant, is a member of the staff of the school and will, of course, meet whatever professional educational standards are set by the school for the type of work involved. Health educators may be employed jointly by health departments and school systems. They are also employed by voluntary agencies. The educational qualifications of a health educator, whether employed by a governmental or by a voluntary agency, should meet generally accepted standards.

This report proposes desirable areas of competence for the health educator, based upon the functions which he is expected to perform. The recommendations are made for the guidance both of officials responsible for the appointment of health educators and of individuals looking forward to careers in health education. The professional standing of persons now performing creditable service as health educators has been established. Successful experience and demonstrated ability should be recognized at the present time as evidence of professional qualification.

* The Committee on Professional Education of the A.P.H.A. publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

II. THE FUNCTIONS OF HEALTH EDUCATORS

The following functions are believed to be essential for carrying out complete community-wide programs in health education. Such programs include health education in the schools and health education with the general public. It is recognized that there is an increasingly close relationship between these two phases of health education. Health educators in various positions will be expected to undertake some or all of the following functions or activities which involve the formulation of plans and methods, the application of specific technics and skills, the supervision of the work of others, and the maintenance of group relations. A job analysis of existing positions reveals wide variations in their scope.

The functions of health educators in community-wide programs of health education are:

In accordance with the administrative policy of the health department or other employing agency:

1. To be responsible for assistance in planning and organizing a program of health education of suitable scope and activities to meet adequately the needs of the community, state, or area to be served. This includes at the outset a study or survey of the needs, the determination of health problems which may be solved, at least in part, by the educational process, and an appraisal of resources.
2. To assist the community in organizing itself to find and solve its health problems.
3. To assist in establishing and maintaining close coöperative working relationships between all agencies (official and nonofficial) which may contribute to health education.
4. To aid in the planning, development, and conduct of training programs for employed personnel, in accordance with the policy of the agency involved, for (a) health agency personnel, (b) school personnel, and (c) personnel of other agencies.

Nearly all public health personnel have important educational opportunities. To increase the effective use of these opportunities is an important function of health education leadership.

5. To give aid in accordance with the policy of the institution concerned, in planning the health education aspects of pre-service training programs for professional personnel, including (a) public health personnel, (b) school personnel, and (c) others.
6. To provide consultation and guidance to various individuals and groups (such as Parent Teacher Associations, service clubs, and others) in developing and improving their health education activities.
7. To assist in promoting, organizing, and guiding study programs in the field of health for adult and group-work agencies, such as divisions of adult education, Young Men's Christian Associations, and similar groups.
8. To contribute to the improvement of the quality of the health education of the school child in accordance with the standards and policies of the school system.
 - a. Through aid in planning school health programs and curricula of health instruction
 - b. Through conferences with teachers, supervisors, and school administrators
 - c. Through such other activities as the school may desire
9. To organize and operate an informational service to provide answers to inquiries and to supply source materials and source references in answer to requests.
10. To be responsible for the preparation, selection, assembly, and distribution of health education materials, using the services of special technicians and health experts as necessary. Such materials include:
 - a. Reports and other printed materials
 - b. Visual aids, such as motion pictures, photographs, graphic materials, exhibits, and posters
 - c. News releases
11. To organize and assist in conducting a speakers' bureau, conferences, meetings, and radio programs.
12. To see that there is established a program of continuing appraisal of health education methods and materials in order to evaluate the effectiveness of health education procedures.

III. BROAD EDUCATIONAL BACKGROUND

The procedure used in determining the educational qualifications here listed, was to analyze each of the above

functions in terms of needed professional qualifications and to group these qualifications in suitable areas.

Certain facts should be borne in mind in approaching this discussion. Not all positions in health education, as indicated above, are of the same scope. The health officer or other appointing authority may not deem it necessary to require all the qualifications listed below for every position. They are the qualifications believed desirable for the director of a large and complete program. Nevertheless it is believed that the continuing improvement in the training of health educators will provide more and more workers who have this training, and that such a person will eventually prove most useful.

Experts in various technics who are not health educators are commonly needed to assist in editorial work and in the development of films, exhibits, and other graphic materials. The health educator concerned with the production of such material will know the nature, limitations, and possibilities of the processes involved. He will know how to work effectively with printers, motion picture producers, and other specialists. This report does not consider the qualifications of these technical experts.

It is clear that the health educator will be helped by broad cultural background and by a knowledge of (a) the structure, functions, and care of the body, elements of the commoner pathologic processes and elements of epidemiology in its broadest sense; (b) motivation and behavior in human life; (c) society as it is constituted—social forces and their control; (d) forces which affect living—environment and economics; (e) the scientific method in approaching the process of living, distinguishing science from pseudo-science; and (f) the processes of education—why we learn and how we learn.

There is also need for knowledge and skills which are more specifically professional in nature. The division between essentially basic preparation and strictly professional training cannot be readily drawn. Neither is it feasible to indicate here a specific training program in terms of institutions to be attended, degree secured, years of study or specific courses taken.

Some health educators have begun training for this field immediately upon reaching the university level. More will do so in the future. At the same time it is recognized that many of the professional fields in the health and social sciences, including education, contain many of the elements of training which are desirable for the health educator. Many successful health educators have acquired their training through supplementing the training in one of these professional fields by study in those previously omitted areas of knowledge which are required for health education. It is not feasible to discuss here the entrance into health education from various professional fields. We shall not attempt to define optimal training. We shall attempt to state the essential qualifications.

Present requirements in the training of health educators should be sufficiently flexible to be adapted to the scope of work required from the individual in question. Without attempting to indicate subjects of instruction or the division between fundamental and professional study, and based upon the duties to be performed in a complete program of health education, there is listed below the areas of knowledge and skill considered desirable for professional competence in health education. Well known areas of knowledge are listed in brief, general terms, while some of the specific skills needed are listed in more detail.

Desirable qualifications are:

1. Basic cultural education, including the de-

velopment of appreciations and skills in the use of the English language

2. Basic science education, including physics, chemistry, biology, anatomy, physiology, and bacteriology
3. Training in education and educational psychology to provide a knowledge of and functional experiences with
 - a. The nature of the learning process, involving individual psychology, interests and reactions, and indirect as well as direct learnings
 - b. The principles and practices of education
 - c. Methods and possibilities of adult education
 - d. The nature of the school health program, including health services, physical education, and other activities
 - e. Methods of educational evaluation and their possibilities and limitations in respect to the evaluation of health education programs
 - f. Curricula and curriculum development in public schools and in schools of higher learning
 - g. Educational supervision and administration
 - h. Existing practices and viewpoints of professional groups for which in-service training is provided, and recent trends in their education
 - i. How to organize and conduct field training for students at the pre-service level (in the case of a field station for professional training)
4. Social science education to provide an appreciation of the importance of respect for human personality and a knowledge of
 - a. Racial, social and cultural characteristics of the people and their mores
 - b. The significance of the economic status of population groups
5. Education in the field of hygiene and public health to provide a knowledge of
 - a. Physiologic hygiene, including personal hygiene, nutrition and mental hygiene
 - b. Environmental sanitation
 - c. Basic principles in the organization and administration of public health
 - d. Methods of communicable disease control, including the nature of the causative organisms and methods of transmission
 - e. Public health statistics and principles of statistical reliability
 - f. Survey methods
 - g. Relative importance of health problems and mode of attack

6. Training in the area of public administration to provide a knowledge of
 - a. Governmental and community organization
 - b. Community agencies, their functions, aims and interests
 - c. Technics for the successful interview and consultative conference (particularly in public school work)
 - d. The qualities of leadership, how to discover leaders and how to work with them
 - e. Group-work methods
 - f. Principles of planning
7. Training in special skills required in health education to include ability in public speaking and the conduct of public meetings and knowledge of
 - a. Methods and materials in health education, their possibilities, and limitations
 - b. The evaluation of sources of material and information
 - c. How to write informative and friendly letters
 - d. How to compile bibliographies
 - e. Filing and clipping methods
 - f. How to write and edit material for publication
 - g. The nature of the printing and duplicating processes and their use
 - h. How to distribute educational material effectively
 - i. The nature, preparation, and use of visual aids
 - j. Possibilities of community participation in the development of educational material
 - k. Press relations and technics
 - l. Radio methods and technics
 - m. Conference technics
 - n. How to organize, advertise, and conduct meetings

Carefully planned and supervised field experience and "internship" should be regarded as an important element in the training of the health educator and in the development of skill and ability in the field of health education.

Personal Qualities

A candidate for a position as health educator should possess such personal characteristics as creative ability, lead-

ership, good personal health, good judgment, pleasing personal appearance, common sense, and adaptability. Such important characteristics, along with the ability to work with people, the ability to size up and meet situations, and the ability to present pertinent facts simply and effectively, are not guaranteed by academic records in formal courses of instruction. The health practices of the health educator himself are also important.

Length of the Training Period

If one were to enter upon a program of planned study in the first year of university life, this essential training could not be secured, we believe, in less than 5 years. Study beyond this point would probably be desirable, especially for those aiming for positions of larger responsibility.

If such a 5 year program were followed, the essential basic preparation could be obtained by a 4 years' course leading to a Bachelor's degree with major emphasis upon: (1) the basic health sciences, (2) education, with emphasis upon educational psychology, and (3) the social sciences.

In such a case, the graduate work would include supplementary courses in the above and allied fields, courses to give a working knowledge of the public health program and its operation, and courses in health education, plus supervised field training wherever pos-

sible. The content and extent of the graduate work required would vary according to the amount of undergraduate preparation and the interval between undergraduate and graduate study and the quality and type of experience the individual has had.

The Place for Graduate Training

It is recommended that programs of professional study in health education be offered in those institutions which are providing professional education in other fields of public health, and which have available the required instructional facilities. Field training stations are desirable.

"IMPRESSIONS OF AMERICA"

"Report of W. M. Frazer, O.B.E., M.D., M.Sc., D.P.H., Barrister-at-Law, Medical Officer of Health of the City of Liverpool, containing his Impressions of America After His Recent Visit" will bring modest, humorous, attentive Dr. Fraser pleasantly to the minds of many who had the privilege of adding to his "impressions" when he visited the United States last fall.

A reading of his report, which occupies 28 pages, underlines again the truth that "He who bring home the wealth of the Indies must carry the wealth of the Indies with him. So it is in travelling. He who would bring home knowledge must carry knowledge with him."

Dr. Frazer discusses our geography and our demography, the governmental system, health department organization, social conditions, general education, medical education and research, public health, hospitals, hotels, railways, war attitudes, and much more. It is all astutely appreciative.

Some samples of Dr. Frazer's "Impressions":

In the United States highly favourable living conditions have been created as a consequence of the conquest of a large and richly endowed territory during the past 150 years. The success of the Americans in bringing under man's control in this comparatively short space of time a vast country possessing such diversified geographical features and such abundant natural resources is one of the miracles of history. But this triumph over nature has given to the average American the highest standard of living ever enjoyed in any large community and in any age, and his genius for political and social organisation has produced the American way of life—a phrase hard to explain because it is a mixture of many things, of business, high spirits, sport both amateur and professional, comfortable houses with central heating, and

every imaginable "gadget," the hire purchase system, the cheap and very efficient car which is the open sesame to the kind of life the American likes to lead, the country club, iced water at every meal, palatial hotels in most cities, and places of amusement everywhere. Most of these things are good, but a recital of them does not tell the whole story about the attitude of the typical American towards life. It is not quite as materialistic an attitude as it appears at first sight. There is another and equally important side to it. Americans are interested in education, literature and art. Their interest in education has produced a system of primary schools, high schools, colleges and universities which—at least in the larger centres of population—give opportunities unsurpassed anywhere in the world to boys and girls with ability to climb the highest rungs of the educational ladder. There are universities and other centres of higher education in every state and almost every city—even the smallest. Some of these institutions may fall below British standards (although many are highly efficient) but they strive to keep abreast of the times, they experiment and they are not afraid to scrap what they have done and to try again. Americans are accustomed to pioneering conditions in regard to many aspects of life and they are used to taking risks both in their business and public affairs. I was fortunate in being able to see something of the higher educational system as I had the opportunity of visiting the Universities of Harvard, Columbia in New York, St. Louis, Chicago, Buffalo, Boston and Toronto. These universities, mainly great city universities are excellently staffed and magnificently housed and equipped and their standard of teaching and research is as high as in corresponding institutions in this country.

Some of the features in the public health system in Great Britain are frankly needed owing to poverty or at least to the relatively low standard of living: in a country with a high standard of real wages like the United States comparatively few persons require assistance of this kind except during the rare periods of industrial depression. One favourable circumstance in regard to the health of the community is that American towns are not so congested with buildings as

in this country—streets are wider, there is much more open space and there is practically no smoke in the atmosphere even in the most highly industrialised cities. The last-named feature appears to me to be of great importance. No person who has not visited the United States and lived in its clean and wholesome urban areas can appreciate the enormous damage which the almost uncontrolled emission of smoke into the atmosphere does in this country—damage to health, to buildings and to furnishings and clothes. Heating in American buildings, both domestic and commercial, is almost universally central heating by oil, gas, electricity or steam relayed from centrally-situated depots. As one result of the clean atmosphere of American cities the incidence of respiratory diseases both in adults and children is very low. This is part of the explanation of the extremely low infantile mortality rate in such highly-industrialised cities as Chicago (28.8) and Detroit (30). When one considers the high infantile mortality rates in Liverpool (82 in 1942) and other English industrial areas, the corresponding figures for some American cities appear almost unbelievable, especially as birth-rates there are usually higher than in this country.

I have already indicated that the emphasis in connection with public health problems is often differently placed in the United States than in this country. Immunisation against diphtheria is there taken very seriously, and in almost every large American city a very high percentage of children (in some cases approaching 100%) are so immunised. In estimating the value of this work in reducing the incidence of diphtheria epidemiological considerations such as secular variations in the prevalence of this disease and the mild type of organism responsible for it have to be taken into account, but, nevertheless, hygienists in the United States ascribe the fall to nearly vanishing point in the incidence of diphtheria, in some areas, almost entirely to the wholesale immunisation of the child population.

Legislation in the United States on the subject of milk supply, although it varies somewhat in the different States, is, on the whole, more drastic and more effectively administered than in Great Britain. Perhaps, in one way at least, their problem is a simpler one since the amount of tuberculosis in cattle has always been much less in the States than in this country. During recent years a campaign for the eradication of tuber-

culous cows throughout the whole country has been undertaken. . . . So successful has it been that a very large percentage of all milch cows in the United States of America are tuberculin tested, and there are now relatively few reactors. To make assurance doubly sure, milk from tuberculin-tested cows is also pasteurized and bottled so that the risk of contamination on the way from the cow to the consumer is avoided. Partly because of the safety of the supplies, but, no doubt, partly because of its value as a food, milk is highly popular in the United States, and the consumption per head of the population is far higher than it is in this country, averaging about a pint per person per day. It would cause no surprise whatever in an American restaurant or hotel if one asked for a glass of milk at dinner instead of coffee—quite a number of other people will be doing the same.

A word or two about the American war effort and their attitude towards the war. I found nobody amongst the hundreds of people of all types that I met who was not heart and soul in favour of the most energetic prosecution of the war until complete victory crowns our joint efforts; and although there is a little grumbling, as there was in this country, when some of the comforts of life are taken away, this is merely a superficial reaction which does not reduce in the slightest the stern resolve of the American nation that this threat to the way of life of the democratic countries shall never occur again.

NEW ITEMS FOR YOUR SAFETY

PORTFOLIO

A "Safety Guide for the Farm and Home Front" is available through the Department of Public Services, General Mills, Inc., Minneapolis, Minn. Check lists under such headings as "What Are the Danger Spots on Our Farm?" "Danger Spots in the Barn and Barnyard—Where Are They?" "Is Your Home a Haven of Safety?" are intended to engage the participation of the whole family in a program of accident prevention. The booklet is designed for members of rural youth groups and their leaders, including, of course, teachers.

J. R. Williams, famous cartoonist

whose series entitled "Out Our Way" appears in newspapers all over the country, is doing 12 poster cartoons for the Division of Inspection and Accident Prevention of the Maryland Casualty Company, Baltimore, Md. The first has been distributed; others will follow from month to month. Black and white, size 11" x 14", the June cartoon is entitled "The Hard Way." It depicts a workman watching the overalls just ripped from him, as he oiled moving machinery, twist and turn, while a wise foreman keeps the machine running to give the oiler a realistic lesson in what his carelessness might have done to him.

Safety material can further be supplemented by "Safety Speeds Production," a message directed to supervisors, for which the Division of Labor Standards, U. S. Department of Labor, Washington, D. C., is responsible. While it is for the use of foremen and others in large war plants, much of it is applicable to any work-place, large or small. Two pages answering the question "What are some good house-keeping aids?" present a partial checklist of simple precautions in work-places so obvious they may easily be overlooked.

And of course you know about the American Safety Standards published by the American Standards Association, 29 West 39th St., New York, N. Y. They include industrial and school lighting, safety code for industrial sanitation, and safety rules and codes for all manner of manufacturing operations. The *List of American Standards for 1943*, of which the section on safety is a part, will be sent free of charge by the A.S.A. Standards approved by the A.S.A. represent general agreement of all interested groups. The American Public Health Association has had a part in the formulation of some of the standards listed and is participating currently in the revision or preparation

of others. (See pages 287 and 288 of the March JOURNAL.)

DON'T ADDRESS MARY P. CONNOLLY AT
DETROIT ANY MORE!

It will be hard to remember, but since June 1 Mary P. Connolly's permanent address has been Dushore, Pa. She has completed 25 years of service with the Detroit Health Department and has done what she said she would do—retire. She gives up her post as Director of the Bureau of Health Education of the Detroit Department of Health, which she has occupied since 1921, but not her interest in the specialty with which her name has become synonymous. After her Victory Garden has been harvested at Dushore, Miss Connolly will spend part of her time in Ann Arbor, teaching Community Health Organization in the School of Public Health.

Miss Connolly began her public health career as a nurse in the Detroit Health Department, after graduating from the St. Agnes Hospital, Philadelphia. At that time Detroit with its meager health facilities was struggling with an epidemic of influenza and the problems of the war industries. After three years with the nursing division, she was made Director of the Bureau of Health Education and has developed this service into its present far-reaching community-wide program which carries the message of good health to all Detroit citizens. The personnel of the bureau has increased from one in 1921 to fifteen in 1943, and has an annual appropriation for salaries alone of nearly \$50,000. During these 25 years the Health Department has grown from a small organization of a few hundred employees to one which now commands the services of 2,200 individuals and spends annually four million dollars of tax money. The phenomenal reductions in the death rates from preventable causes and the reduction of the

crude rate for Detroit to the lowest among the larger cities of the world, is due in no small measure to the seeds of health education sown by Miss Connolly and her small staff of trained workers.

In addition to her degree in nursing, Miss Connolly has received the Master of Science from the University of Detroit. For 20 years she was a non-resident lecturer in the field of health education at the University of Michigan, and of late years she has been, as well, special lecturer in health education at Wayne University. She served for six years as a member of the Governing Council of the Association; five years as Secretary of the Section on Health Education; one year as Chairman of this Section. She is now a member of the Section Council.

Her name on the faculty list of the several Health Education Institutes sponsored by the Association at Annual Meetings has been responsible for many an enrollment among those, and their name is legion, who know that anything she is connected with will be worth while.

CREDIT LINES Salutes Miss Connolly and her work of the past 25 years. It holds in reserve another accolade, sure to be conferred later, for what she will do in the future.

TRIBUTE TO HEALTH EDUCATION FROM AN UNEXPECTED SOURCE

Visual evidences of the effects of all the health education that has been done in this country are many, we think, as we admire individual and collective members of the younger generation. When we were seventeen, were our backs and legs so straight, our teeth so gleaming white, our hair so shining with cleanliness and health? Any group of twenty high school youngsters today could give a similar group of let's say twenty-five years ago cards and spades. The way they dress now has something to do with it, of course, but

what the clothes adorn or what adorns the clothes, appears to be better material, esthetically speaking, than what we had to offer.

There is clinical evidence as well that health education has taken hold. An interesting bit comes from Dr. Frank E. Adair, Associate Professor of Clinical Medicine at Cornell University Medical College and guiding genius of the American College of Surgeons' register of cured cancer cases. Says Dr. Adair:

Education of the public in the matter of cancer control is definitely going ahead. A clinical sign which supports this statement is the size of the cancers operated on today as compared with those that came to the operating table fifteen to twenty years ago.

Dr. Adair prophesies that the teaching of the subject of cancer in connection with the biological study of growth in the secondary school systems of Westchester County and in certain parts of the New York City school system will undoubtedly save the lives of many people. It undoubtedly will, but that is for the future.

The majority of the patients who are presently bringing early and small cancers to Dr. Adair's attention are certainly not the members of the younger generation we have been eulogizing and who are now being taught about the proliferating cell. They are the high school students of fifteen and twenty years ago who got their education in health the hard way, without benefit of classroom instruction from kindergarten on, without benefit of the solicitous care they, as parents, are giving their young today. That is what makes this report from experience so encouraging.

If we didn't have our quart of milk a day while we were growing up, if our wintertime citrus fruit intake was limited to the Christmas orange in the toe of the stocking, if our doctors never saw us except when we were flat on our

backs in bed, nevertheless we of this older generation have been exposed to health education somewhere along the line and are applying to ourselves and to our children what we have learned.

DR. GREGG ON SPEAKING AND WRITING

It is good to know that Captain John Lentz of "Credit-Lines" fame still keeps his appetite for literary caviar and has the opportunity now and then for satisfying it. Recently he sent one of his erstwhile associates, who reconciles herself to the day by an early morning dip into "the literature," the commencement address delivered by Dr. Alan Gregg, Director of the Medical Sciences of the Rockefeller Foundation, at The Jefferson Medical College on March 4, 1943. This address entitled "Language and the Practice of Medicine" was printed in *The Diplomat* for April.

Some of Dr. Gregg's remarks to fledgling doctors may prove interesting to their more experienced colleagues:

On being understandable to one's patients: "For four years you have considered important the opinion of medical men. Now you will have to reckon with the opinion of laymen. Can they understand their doctor? . . . They will be uneasy and perhaps resentful if you aren't a master of simple exposition and plain narrative about things they do not understand and yet may wisely fear."

On current performance in the art of medical and scientific writing: "The common level of medical and scientific writing in our professional books and journals already constitutes the most serious internal limitation to medical education and research. The usual level of professional writing is painful not merely to editors. Even after passing editorial filters, the virus of wretched writing can inflame, insult, and exhaust a clear-minded man . . . even with the benefit of hours of edi-

torial improvement, the medical literature of today exemplifies all too fully the biological adage that life is choked by its own secretions."

On "the unreflecting use of adjectives and adverbs": "Adjectives, like certain antigens, develop their own antibodies."

To those who "think it is too late to learn to use words effectively": ". . . Unnecessary humility endorses needless resignation. Instead of giving up now, you could better admit that *mastery of words comes slowly because language demands, like every beautiful instrument, long practice and discriminating use.* Language cannot take the place of thought, or of action, or of listening, but 'that one Talent which is death to hide' cannot be neglected by those who must lead their fellow men."

NEWSPAPER SUPPORT, MICHIGAN STYLE

H. E. Miller, Resident Lecturer in Public Health Engineering, University of Michigan, sends an editorial published in *The Ann Arbor News* for May 13 which is worth quoting in full. Mr. Miller tells us that the course referred to was one on basic sanitation, designed to prepare these "sub-sanitarians" for the replacement of trained sanitarians in Michigan health units who have been commissioned in the Army.

Mr. Miller's comments on the editorial are worth quoting, too. He says: In this editorial, an understanding of the relationship that the public health engineering section bears to the school as a whole, and its essential functions in the overall structure of the school is set forth in a way that is frequently not visualised by even well informed public health authorities. The fact that it was uninspired and unexpected, but purely the expression of a newspaper man lends hope to the thought that public health may be accomplishing more than is realized in ways of developing a better general understanding and appreciation of its efforts.

This is the editorial:

DEDICATED TO PUBLIC HEALTH

Completion of a course in public health engineering by 16 men from various cities of Michigan, who now will be known as "sub-sanitarians," accepting positions of responsibility in their home communities, offers a glimpse into the future of services of a highly practicable nature by the University's School of Public Health.

This school soon will occupy its new building on Observatory St., bringing together for the first time its offices, laboratories and staffs, engaging in varied activities but now scattered about the campus.

That name, School of Public Health, indicates the practical purposes to be served. And the experiences of the handful of "sub-sanitarians" offer just a glimpse of those purposes.

The 16 will take the places in community health departments of sanitarians who have gone into the armed services. They will aid public health physicians in safeguarding municipalities against epidemics. They have learned how to do this at the School of Public Health, though their instruction covered only three weeks. Now they will have "field work," rounding out the practicability of their training, at the Kellogg Foundation, with headquarters in Battle Creek. They will hold their new position for "the duration."

They did not receive their training primarily at the hands of doctors of medicine. The staff members with whom they came into contact were, mainly, public health engineers, with knowledge based on experience, as well as theory, in the business of maintaining vigilance against the inroads of disease—by inspecting eating places and dairy herds, by controlling insects and rodents, by avoiding water contamination, etc.

But there will be doctors of medicine in the School of Public Health, and there will be intense research into a number of human ills, including some of the most serious, such as malaria, infantile paralysis and influenza. Mosquitoes will be bred for experimental purposes; so will bacteria, of both the harmful and harmless kinds. One experiment now under way in one aspect of water contamination, in the engineering department of the school, offers some prospect of offering a new field of research into the cause and possible cure of some human maladies. In this connection, the housing of the public health engineers and medical research workers under

the same roof will operate for mutual benefit and the public good.

Every phase of public health work will be dealt with in the school—under that same roof. Physicians will be especially trained for public health work; so will other workers in health departments, including the sanitarians—and there will be all those researchers at work—in close proximity, with collaboration made convenient. In other words, several different but related branches of science will be meshed together in a kind of investigating mechanism with the same general objective in view—to keep the public well.

This is an ideal situation. In the past, there has been too much independent research by various branches of science. Medicine and dentistry seldom got together, for example, though they serve common purposes and have overlapping interests. Lately, medicine and chemistry have held closer communion, because of the biochemical drugs coming into widespread use. In the School of Public Health, with well equipped laboratories and highly trained staffs, dealing with separate factors in human problems, but with the same general over-all problem in mind, there will be opportunities for the much-desired collaboration that never before have been presented.

Out of the engineering laboratory may come the clue that will lead to medical research of great value. The investigators in the parasitic disease laboratory are likely to make various discoveries beneficial in the field of public health engineering. The laboratories are separate, but inter-communication is easy in the new home of the school. And out of this school will be a steady flow of students with the knowledge and the training needed to serve the people as guardians of health in a variety of ways.

The formal opening of the School of Public Health, in the near future, will be an important public event. It is not "just another" building dedicated to academic learning. It is dedicated to the purpose of improving ways and means, on a large scale, to keep humanity well. And, considering the equipment in the way of absolutely top-notch personnel and the best in the way of research and teaching equipment that can be produced, the prospect looks very bright. It appears safe to predict that Michigan's School of Public Health will be recognized ere long as one of the great institutions of America, if not of the world.

BOOKS AND REPORTS

Public Health in Manitoba—1941
—*A Report of a Study Made by the American Public Health Association, New York, 1942. 147 pp.*

The study of public health administration in Manitoba is a comprehensive one, which is interspersed on almost every page with recommendations in large type. The report is particularly interesting because the Canadian forms of federal and provincial government and health administration are so different from their counterparts in the United States. The national health authority is the Dominion Department of Pensions and National Health, and in the province it is the Manitoba Department of Health and Public Welfare. Of the latter the titular head is the Minister of Health and Public Welfare who must be a member of the Legislative Assembly of the province. He is responsible for all important decisions of policy and in 1941 was the Attorney General of Manitoba. To his Deputy Minister, who must be a professionally trained medical officer of health, he delegates the direction of the department.

The record is one of much administrative confusion, a need for reorganization, and indeed even a desire for guidance in the matter. The province, chiefly rural and agricultural, has a population of about 700,000. Of this figure roughly 250,000 are in Winnipeg, the largest city. The next center in size, Brandon, is a city of 16,000 persons.

It is reported that the Deputy Minister is an extraordinarily capable leader and administrator, who is able to accomplish much with very limited staff and funds. It is obvious that all

the salaries for professionally trained people are shamefully low.

The study deals particularly with the problems of rural Manitoba, excluding Winnipeg. An outstanding need is for many more full-time local health units. There are only four, three of which are in Winnipeg and its suburbs. The four serve 39 per cent of the total population of the province. The rest is in the hands of 170 part-time medical health officers all but 16 of whom, the so-called municipal doctors, earn their chief livelihood in the private practice of medicine. One cure would seem to be a much more liberal financial grant from the Department of Pensions and National Health at Ottawa. Another vital lesson for the farmer population to learn is that generous investments in public health appropriations can yield worth while dividends in human happiness.

The rather overwhelming administrative and budgetary matters of medical and mental care, including hospital services and difficult abuses in hospital admissions, the public welfare program, and the voluntary or semi-governmental control of tuberculosis, add complication on complication that would stagger a state with completely organized full-time public health administration on the local level. It is no wonder then, that in describing the four full-time local health services the author's comment on one is as follows: "The health department at Brandon seems at present a less promising picture, principally because such a large proportion of the health officer's time is devoted to the medical care program."

HUNTINGTON WILLIAMS.

The Metabolic Cost of Maintaining a Standing Position. *With Special Reference to Body Alignment—By Harriet Graham McCormick.* New York: King's Crown Press (1145 Amsterdam Avenue), 1942. 75 pp. Price, \$1.25.

I find this book very challenging to me as an orthopedic surgeon interested in postural matters, but rather difficult to review because it is descriptive chiefly of all the technical detail of the experimental study. To one interested in clinical manifestations it is difficult to wade through so much tabulated material and then be left to draw one's own conclusions in order to apply the data to everyday needs.

The author's observation, that in the relaxed posture type with back knee, forward pelvis, flexed back and forward head, with minimal energy cost is apparently due to the stabilizing effect of ligamentous tension is probably correct. It should not, however, be the basis for the assumption that such a posture is all right or acceptable, because such continued tension and strain will gradually stretch and relax them, and the posture in time will become worse, thus promoting a vicious circle, which as years go by will tend to promote a wear and tear arthritis. Probably if continued the ultimate metabolic cost could be greater than the increased expenditure by the assumption habitually of the posture generally accepted as "good."

It seems to me that the minimal output of energy is not what is desirable, but rather an output which will maintain a reasonably good posture which will be efficient from the standpoint of health as well as improve the facility of coordinated function required for skilled performance and, as the author states, give the greatest satisfaction. In this I concur in the "implications" discussed on page 60, and will join the group desiring the best posture obtain-

able without too much strain, feeling that in the long run, when the habit is established and such a posture can be maintained more naturally, the metabolic expenditure will be less than shown by these experiments.

It would be of great interest to see the same experiment repeated on the same group after six months to a year of really guided and controlled correction of their postural faults.

C. L. LOWMAN

Democracy Means All of Us—How Communities Can Organize to Study and Meet Community Needs with Special Suggestions for Developing Nutrition Programs in Wartime. *Federal Security Agency—Office of Defense Health & Welfare Services, Washington, 1942.* 30 pp.

This pamphlet, which consists of 18 pages of text and 12 of appendix, can be helpful to the person interested in community organization. Although written to aid in the development of nutrition programs as part of community defense council activities, the principles of organization and procedure outlined apply to all types of community work.

Prepared by a group of outstanding experts in the field of nutrition, education, and public health, the pamphlet is of unusual interest, because the procedures advised and problems encountered in communities of various size are dramatized. Although brief, the booklet is surprisingly complete and can be recommended to both the lay and professional worker.

Particularly valuable is the emphasis on and suggestions for

1. Clearly defining objectives in the planning stage.
2. Reaching all the people—(hence the title, "Democracy Means All of Us").
3. Youth participation.
4. Evaluation. Too often evaluation is neglected or considered only after the opportunity to secure adequate data is passed, and

the authors clearly indicate the importance of considering evaluation during the planning period.

The appendix contains a good bibliography, organizational charts, a list of helpful organizations, suggested questions to assist in studying community problems and resources, and a form for nutrition studies.

W. R. WILLARD

Flying Men and Medicine—By E. Osmun Barr. New York: Funk and Wagnalls, 1943. 254 pp. Price, \$2.50.

The book is largely a discussion in lay language of the Civil Aeronautics Authority physical examination for flying. Such a subject makes dull reading at best. Physicians will not want to read it because it is too elementary; airmen will find it tedious and in some parts difficult to understand. It is not likely to put its message over to the prospective flyer for whom it was written.

Further, it seems undesirable that the applicant for flying training know too much about the physical requirements and the reasons for them. This has resulted in the circumvention of the requirements by subterfuge, and the unwitting medical acceptance of individuals for flying training with defects which are dangerous.

There are unusual statements, especially on the physiology of flight, which make it clear that the author is not intimate with some of the recent advances in this particular field.

There are several passages of unrestrained emotionality about flying, with change in tense, which one would expect of a less mature type of publication.

Throughout one gets the impression that the book was written, or at least conceived, quite some time ago and has been published now simply because of the renewed interest in aviation and aviation medicine.

The prospective flyer and the flying man of today will find it of limited value.

CHARLES E. KOSSMANN

Nutrition Programs for Industrial Employees (No. XIII). 8 pp. December, 1942. Price, \$.20.

The Medical Department in War Industries (XIV). 8 pp. December, 1942. Price, \$.10.

The Feeding of War Workers—A Selected Annotated Bibliography (No. 70). 15 pp. October, 1942. Price, \$.15.

Medical Service in Industry—A Selected Annotated Bibliography with Particular Reference to Health Programs in War Industries (No. 71). 11 pp. December, 1942. Price, \$.10.

Industrial Relations Section, Department of Economics and Social Institutions, Princeton University, Princeton, N. J.

Nutrition Programs for Industrial Employees—There is no subject in the field of public health which has attracted such wide attention from all groups in the population as has the subject of nutrition. It almost seems that over night we discovered that the American population was and is, in some respects, suffering from malnutrition.

The present pamphlet outlines the important aspects of the nutritional program for industrial employees. Naturally, in this brief space, only the over-all picture may be presented, but the present pamphlet is complete enough to give anyone interested in this subject an excellent knowledge of the fundamentals of the practical approach to its solution.

The Medical Department in War Industries—The present trend toward group medical practice and socialized medicine has led to the discovery of the importance of the medical department in industry as a nucleus for public

health and medical practice. As a consequence, the medical departments in industry have, in the last five years, grown tremendously in numbers and importance. The functions, both direct and indirect, of such medical departments are set forth in this very brief pamphlet in a topical form.

This is an excellent digest for use by those agencies interested in developing and fostering medical departments in industrial establishments since all of the fundamental factors are set forth in a brief and orderly presentation.

The Feeding of War Workers—To one desiring to make a rapid acquaintance with progress in the field of industrial nutrition, the present pamphlet is of interest and value. The bibliographic items selected by the writers are valuable, chiefly because of their succinct and objective presentation.

In general, the field has been fairly well covered but, of course, the subject of industrial nutrition can hardly well be presented in 15 pages.

Medical Services in Industry—This 11 page mimeographed leaflet makes no pretense at being complete but rather presents a selected bibliography of the subject of medical service in industry.

The subject matter is divided into five parts; general discussions, reports of service of company programs, reports and recommendations of medical associations, special problems and programs in small plants, and finally, industrial health service in war time.

Naturally such a brief pamphlet cannot make any pretense at completeness but the material presented is among the best in the field and is certainly suggestive for those wishing to make an immediate and rapid contact with the problem of medical services in industry.

LEONARD GREENBURG

Exploring the Dangerous Trades
—*The Autobiography of Alice Hamilton, M.D. With 8 illustrations by Noah*

Hamilton. Boston: Little, Brown, An Atlantic Monthly Press Book, 1943. 433 pp. Price, \$3.00.

Public health workers and others interested in the development of industrial hygiene in the United States will find this autobiography with its sociological, political, and philosophical observations particularly stimulating at this time of increased concern for the health of the worker. The author began her numerous and diverse field investigations in the pre-workmen's compensation days of 1910, when she coöperated in the study of occupational diseases in Illinois. Subsequently reference is made to federal surveys which included, among others, the investigation of high-explosive production, and the effect of the air hammer on the hands of stonecutters; to attendance at meetings abroad of the International Congress of Occupational Diseases and Accidents; and finally to the study in 1938 of carbon disulfide poisoning in the viscose rayon industry. Thus three decades of industrial hygiene are presented, an account which constitutes a valuable contribution to a history of the health of the American worker.

W. M. GAFARER

Nursing History in Brief—By Minnie Goodnow (2nd ed. rev.). Philadelphia. Saunders, 1943. 338 pp. Price, \$2.25.

The text is intended for schools of nursing giving "courses of fifteen hours or less" and includes "a short outline of facts of nursing history." These facts are broad in scope, going back to 1300 B.C. and extending down to the present time. Each chapter is concluded by means of a summary of important points to remember. The text contains 103 illustrations, largely reproductions of portraits. Chronological outlines of general history and of nursing history are also included. The influence of religious and military orders

on the development of nursing is mentioned.

The treatment of the subject of history is purely factual and not interpretive, and since the text must be a short one the facts are sketchily presented. For example, the development of public health nursing in tuberculosis, child care, school nursing, and industry is treated in one page only. There is nothing of the tremendous development of public health nursing in official agencies in rural areas—the most outstanding recent achievement in this field. Little is said of the political, social and economic factors in general history which have their counterpart in the development of nursing, not even the influence of the Social Security Act upon the education and distribution of nursing in the United States.

One might raise a number of questions as to what historical approaches will give the best results when a short intensive course must be given. Should the approach be factual or interpretive? Should the many facts be sketchily presented, or should they be selective and grouped around large central themes? Should the approach be functional rather than chronological—the outstanding problems of nursing today and some interpretation of how they evolved?

The usefulness of this text will be largely to those instructors, and there are many of them, whose approach is factual and chronological.

MARY ELLA CHAYER

Twenty Years of Medical Research—By Dorothy White Nicolson. New York: National Tuberculosis Association, 1943. 97 pp.

This is an account of the work and accomplishments of the Committee on Medical Research of the National Tuberculosis Association. The outstanding features of the work of this committee concern the nutrition and chem-

istry of the tubercle bacillus. This has resulted in the most complete analysis made of the organism, and the isolation of the active principle of old tuberculin—Purified Protein Derivative, known as PPD. This can be prepared from human, bovine or avian tubercle bacilli. In 1941 a large quantity of PPD was prepared for use in standardizing tuberculin, a project of the Health Committee of the League of Nations. The Carnegie Corporation furnished funds for purchase of a quantity which is in the custody of the U. S. Public Health Service until the war is over, when it will presumably be sent to Copenhagen where other standards are kept.

The fine work of Dr. Florence Seibert is well known. It has been recognized all over the world and she has been the recipient of the highest honors.

We wish it were possible to mention others of the various studies carried on and the names of the workers responsible for them.

The pamphlet gives also a list of the grants by the committee and a list of the organizations which have contributed financially to the work. There is a very valuable and complete bibliography extending from 1921 to 1942 inclusive.

The compilation of the entire book has been done by the secretary of the committee from its inception. The record is one of extensive research with some striking results. The National Tuberculosis Association is to be congratulated on its part in bringing about this work and the publication is a valuable one.

MAZÛCK P. RAVENEL

Primer of Allergy—By Warren T. Vaughan. St. Louis: Mosby, 1943. 176 pp. Price, \$1.75.

The demand for a second edition of the *Primer of Allergy* has fulfilled the prediction of the original reviewers that this little book would become popular. The object of this book as stated by

the author, is to impress upon the patient the need for a thorough understanding and coöperation in the problems presented to the physician by an allergic patient.

This story of allergy explains in a simple way the complex symptoms presented the physician in the majority of cases. Anyone who has read this book before consulting an allergist certainly should be able to understand the whole subject in a clearer light.

The subject matter is approached in a humorous and practical manner. The patient is encouraged to become aware of his own environment and its contributions to his especial case. One is surprised that so much good information can be given to the patient without going into real technical explanations. A much needed and timely explanation to the public on the subject of allergy is contributed by this book.

J. RICHARD ALLISON

An Evaluation of Dental Health Literature—By Vern D. Irwin and Netta W. Wilson. Minneapolis: Bruce Publishing Co., 1942. 58 pp. Price, \$0.50.

Courageous indeed were the authors of this booklet, for they have studied the "mistakes that have been made by many sincere and intelligent writers on this subject (dental health)."

To prove that laymen have been misled by "inaccurate, imprecise, contradictory, misleading, impractical, or over-technical" statements, 2,441 items from state health department publications, dental organization material, books, periodicals, and newspapers were analyzed.

How the authors attacked inaccuracies can be illustrated by the following:

Citing from a state department publication, "Refined foods may be used without harm so long as adequate amounts of the protective foods are utilized," the comment is made by the

writers that this opinion is "controversial, and directly opposed to those who present evidence showing that refined foods, especially refined sugars, may harm the teeth."

A chapter on Adaptation of Dental Health Literature will challenge and instruct the health educator no matter what his field may be.

The reviewer is convinced that hereafter before he thrusts reading material upon his public, he will carefully review Irwin's and Wilson's criticism and attempt to adopt their suggestions for the presentation of dental health education material.

With such thoughts is it surprising that your reviewer commends this work as one that will contribute to more realistic and effective dental programs?

J. M. WISAN

Understand Your Ulcer—A Manual for the Ulcer Patient. By Burrill B. Crohn, M.D., F.A.C.P. New York: Sheridan House, 1943. 199 pp. Price, \$2.50.

The author prepared this manual to be put into the hands of the patient suffering from gastric or duodenal ulcer. He states his specific purposes to be "to give you (the patient) an intelligent understanding of what your doctor says and what he means and so avoid many questions on your part. We aim to give you self-confidence and to allay your fear if you have any." The book scarcely succeeds in either of its purposes.

It devotes too much space to the details of symptoms, complications, treatment, both medical and surgical, including illustrations of operations and surgical devices. Overemphasis is placed upon the lack of specific cause of ulcers and the divergence of opinion among medical men as to treatment. This helps neither the patient nor the profession. One wishes that more attention had been given to the hygiene

of the digestive tract and an effort to provide mental hygiene guides for the patient. Part II contains specific information on preparation and cooking of diets recommended by the author.

WALTER H. BROWN

This Is My Life—By *Agnes Hunt*. New York: Putnam, 1942. 237 pp. Price, \$2.50.

The fact that these reminiscences are now reprinted for apparently the third time bears testimony to their charm, and perhaps one should first rejoice that the volume is at last available in an American edition. This tale of the brave descendant of Shropshire gentry who became so intimately connected with Robert Jones and modern efforts in the behalf of the orthopedically handicapped will appeal to more than one kind of reader. Certainly the child psychologist should find food for thought in the life of one whose early childhood seemed to lack every vestige of security and affection. Those interested in the physically handicapped, too, will find here a tale at which to marvel. And even the casual reader may find here a mixture of humor, courage, and mid-Victorianism which will please him.

LEONA BAUMGARTNER

Noxious Gases and the Principles of Respiration Influencing Their Action—By *Yandell Henderson and Howard W. Haggard*, 2nd ed., No. 35. New York: Reinhold Publishing Corporation. 287 pp. Price, \$3.50.

The authors of this book are well known for their researches in applied physiology and for their skillful exposition of both technical and general aspects of their field. It is not surprising, therefore, to find that the second edition of their standard treatise on "Noxious Gases" is a competent and readable survey of the subject.

Within its limits the book may be

highly recommended. However, it is important to recognize these limits, one of which is hinted in the full title—"Noxious Gases and the Principles of Respiration Influencing Their Action." Approximately a third of the book is devoted to a general discussion of respiration, and the book generally pays scant attention to skin irritants and non-respiratory pathology induced by noxious gases. The decision of the authors to restrict their attention to industrial aspects of the problem resulted in the omission of any treatment of the timely subject of poison gases in war. Phosgene is very briefly mentioned; "mustard gas" (dichlorethyl sulfide) is not discussed at all though it is listed in two tables.

There is a brief bibliography at the end of most of the chapters so that some guidance for further reading is provided. This is particularly necessary in view of the rather elementary character of the book.

ANCEL KEYS

Fundamental Principles of Bacteriology—By *A. J. Salle, B.S., M.S., Ph.D.* (2nd ed.). New York: McGraw-Hill, 1943. 643 pp. Price, \$4.00.

The second edition of this successful textbook is greatly improved by the removal of class laboratory directions to a separate volume. It still contains a considerable amount of advanced chemistry which is emphasized to an even greater extent than in the previous edition. There is some tendency to criticise this trend in textbooks on bacteriology but the present reviewer is definitely in agreement with the author that "no student can intelligently understand or pursue research in bacteriology without first having had a sound knowledge of at least inorganic and organic chemistry."

In the present edition there are 27 chapters, including good discussions of the Bacteriology of Food, Soil, Milk,

Water, etc. There is new material on the electron microscope, bacterial nutrition, enzymes, respiration, etc. Gramicidin and actinomycin are discussed but there is no mention of penicillin. Specific infections, as in the previous edition, are covered in a single chapter along with viruses and rickettsiae. However, discussion of fundamental topics like technic, disinfectants, sterilization, fermentation and putrefaction, growth phases, effects of environment, etc., are complete and specific.

The book is well written and edited and unusually fully illustrated. Bibliographies accompanying each chapter bring the literature generally to within a year or so of the date of publication. A well made index completes the volume. MARTIN FROBISHER, JR.

What the Public Knows about Health—By *Mayhew Derryberry, Arthur Weissman and George Caswell.* Published by the American Museum of Health, December, 1942. 144 pp.

This bulletin constitutes a report of investigations which were carried on at the New York and San Francisco Fairs to determine the extent of the health knowledge of the general public. Since information regarding the type of health knowledge which the public possesses is basic to all programs in health education, this report is directed particularly to those persons working in the field of health education. However, the excellent analysis of results will prove useful to many other workers.

The study was carried on at the New York Fair from April 30, 1939, to October 31, 1939, and in order to increase the number of persons tested and

also to widen the geographic distribution of those tested, the study was extended to include visitors to the Golden Gates Exposition in 1940. In this report are included a description of the physical set-up of the two testing centers and clearly stated information regarding the composition of the test questions and the administration of the tests. The analysis of the findings is well worth reading. In addition to presenting interesting and scientifically reliable facts, this report includes charts and tables which are most helpful to the reader.

The authors state that this report is the "first comprehensive study of what the man on the street knows about health," and their bulletin presents data obtained as a result of testing about 100,000 visitors to the Fairs. These visitors were each given one of the seven different question sheets as they presented themselves at the quiz booth. The tests varied from day to day, the same set of questions being used for all visitors on any one day. As each visitor finished his question sheet, it was automatically scored in a scoring machine which retained the test paper. The visitor was then either given a set of answers or these were mailed to him. Questions were asked on the topics of cancer, communicable disease, nutrition, general health information, superstitions and misconceptions, anatomy and physiology, maternal and child health, venereal disease, and tuberculosis.

What the Public Knows about Health appears in mimeographed form, in an Accobind Folder. This report of fundamental research has a place in every health education library.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Good News—No evidence has yet been uncovered indicating that the increased employment, the harder work, the longer hours, the crowded boom towns have adversely affected the downward trend of the tuberculosis death rate. In the reported sample, every month since Pearl Harbor has registered a lower rate. It is, however, too early for one to become complacent and to neglect any single tuberculosis preventive measure.

ANON. War Time Trends in Tuberculosis. Stat. Bull. (Met. Life Ins. Co.). 24, 5:1 (May), 1943.

Seems Like a Good Idea!—As fluorine in drinking water appears to affect dental caries, this thesis proposes that 1.0 p.p.m. of fluorine be added—as it could easily be—to some municipal water supply for which a competent control area could be selected.

AST, D. B. The Caries-Fluorine Hypothesis and a Suggested Study To Test Its Application. Pub. Health Rep. 58, 23:857 (June 4), 1943.

For Mental Comfort, General Efficiency and Safety—Even though you haven't the remotest connection with industrial hygiene, you can't help but be interested in this sprightly discussion of the use of color in work places. Here is a sample: "So Mary and John meet at noon in the peach cafeteria. And that evening they meet again, one from a rose locker room, the other from a blue, to walk down an ivory hued stairway."

BIRREN, F. Color Technique in Industry. Sight-Saving Rev. 13, 1:3 (May), 1943.

And We Salute You, Sir!—You will surely not want to miss this graceful and informal word of parting from one who remembers the giants of the olden days. Not many there are of us who knew Koch and Loeffler and Klebs and Gaertner and Biggs, and every word dropped by those who did should be gathered up by all.

BOLDUAN, C. F. Some Reminiscences and a Valedictory. Quart. Bull. (City of N. Y. Dept. of Health). 11, 2:23 (May), 1943.

When Women Work for War Wages—Industrial absentee rates have risen from a normal 3 per cent to an all-time high of 8 to 10 per cent. Newly added women workers seem to be chiefly responsible for the larger part of this increase. Youth is another factor. There is a whole six-course dinner for thought in this brief discussion.

DANIELS, L. R. Medical Aspects of Absenteeism. New Eng. J. Med. 228, 24:773 (June 17), 1943.

Mental Comfort for Next Winter's Shivers—Colder homes in the winter of 1942-1943 probably were responsible for only very small increases in respiratory diseases, and in the opinion of some sanitarians more good than harm resulted from fuel oil limitation.

DEAN, J. Fuel Rationing and Public Health. J.A.M.A. 122, 8:511 (June 19), 1943.

Not Blindness But Idleness, the Burden—It will do no harm to any of us to keep intelligently open minds upon questions of the care of the blind even though we don't make a living in this field of public service, so you are hereby cordially invited to taste this discussion of the rehabilitation of the war blinded.

FARRELL, G. For Those in Darkness. Survey Midmonthly. 79, 6:167 (June), 1943.

How Much Do Nurses Cost?—How much will a generalized public health nursing service cost a health department? You may want to know in order to make a budget, or to compare yours with others' experience, or to make changes. You'll find useful figures in this committee report.

GAVERNS, H. Public Health Nursing Costs in a Health Department. Pub. Health Nurs. 35, 6:299 (June), 1943.

Food-borne Infections—Disconcerting evidence of the chances we take whenever we eat runs through this excellent review of recent studies of amebiasis, trichinosis, typhoid fever, etc., etc. Useful source material for your files.

GETTING, V. A. Epidemiologic Aspects of Food-borne Disease. New Eng. J. Med. 228, 23:754 (June 10), 1943.

More Potent Typhoid Vaccine—A purified antigenic material obtained from an *Eberthella typhosa* culture and administered in 1 mg. dosage produced mouse-protective antibodies in greater amounts than 2.4 ml. of standard vaccines, and with less local and constitutional reactions.

MORGAN, H. R., et al. Immunizing Potency in Man of a Purified Antigenic Material Isolated from *Eberthella Typhosa*. J. Immunol. 46, 5:301 (May), 1943.

Day Nursery Meals—Many health officials, who are concerned with the care of children of war-working mothers,

will be helped by this discussion of mass feeding of toddlers.

PELLER, L. E. Eating in Groups in War Time. Ment. Hyg. 27, 2:188 (Apr.), 1940.

Encephalitis Prophylaxis—Should a severe epidemic of the St. Louis or Japanese Type B encephalitis occur it may prove worth while to use a non-infective vaccine, which has shown its protective value in volunteers.

SABIN, A. B., et al. The St. Louis and Japanese B Types of Epidemic Encephalitis. J.A.M.A. 122, 8:477 (June 19), 1943.

And What Are You Doing about This Nutrition Business?—Two sentences from this challenging paper ought to be sufficiently provocative to send you to the issue of the "Reports" in which it is published. There are two other good papers on the same topic which you will not want to miss. Here are the sentences? "It has already taken too long for public health officials to recognize that malnutrition is a problem in preventive medicine." and "We have, to some extent, in this country every dietary deficiency disease known to man."

SEBRELL, W. H., and WILKINS, W. The Rôle of the Health Department in the National Nutrition Program. Pub. Health Rep. 58, 21:803 (May 21), 1943.

Rats!—Community sprees of rat-catching with attending publicity hullabaloo are futile health gestures. Rodent control in cities is an essential public health measure of an entirely different complexion. How it may be accomplished effectively is outlined in an important paper—considering the fact that sylvatic plague may spread some day to our rat-infested industrial cities which are already enjoying an increasing typhus incidence.

SHERRARD, G. C. A Plan for Rodent Control in Cities. Pub. Health Rep. 58, 22, 825 (May 28), 1943.

ASSOCIATION NEWS

THREE-DAY WARTIME PUBLIC HEALTH CONFERENCE AND
SEVENTY-SECOND ANNUAL BUSINESS MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 12, 13, 14, 1943

Headquarters: Hotel Pennsylvania

*PRELIMINARY PROGRAM will be published in
the September Journal*

LOCAL COMMITTEE APPOINTED

The Local Committee on Arrangements for the Wartime Conference and the 72nd Annual Business Meeting is as follows:

Chairman: Ernest L. Stebbins, M.D.
Honorary Chairman: The Honorable Fiorello
H. LaGuardia
Co-Chairman: Edward S. Godfrey, Jr., M.D.
Secretary: Leona Baumgartner, M.D.
Treasurer: Matthew Byrne

Subcommittee Chairmen
Finance: Frank Kiernan
Meeting Rooms: John Oberwager, M.D.
Publicity: Frank A. Calderone, M.D.
Radio: Iago Galdston, M.D.
Reception: John L. Rice, M.D.

NOMINATIONS FOR THE THE GOVERNING COUNCIL

In accordance with the By-Laws of the Association, the Nominating Committee for Governing Council members, consisting of one Fellow from each Section, reports the following nominations for the Governing Council. The By-Laws provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received fifteen days before the Annual Meeting." The Chairman of the Committee is Friend Lee Mickle, Sc.D., Director of Laboratories, State Department of Health, Hartford, Conn.

The other members are: Gordon M. Fair, Engineering Section; Wilton L. Halverson, M.D., Health Officers Section; Albert C. Hunter, Ph.D., Food and Nutrition Section; Robert A. Kehoe, M.D., Industrial Hygiene Section; Hugo Muench, M.D., Vital Statistics Section; Sophie C. Nelson, R.N., Public Health Nursing Section; Alton S. Pope, M.D., Epidemiology Section; William D. Stovall, M.D., Laboratory Section; Clair E. Turner, Dr.P.H., Public Health Education Section; Estella F. Warner, M.D., Maternal and Child Health Section. (The representatives

from the new School Health Section will be elected at the forthcoming Annual Business Meeting.)

There are thirty elective councilors on the Governing Council, of whom ten are elected each year. The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in New York City will be elected for the three year term 1943-1946.

Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

Merit System for Personnel Administration, Delaware, is accepting applications for position of Deputy State Health Officer in Delaware State Board of Health. Salary range \$3,600 to \$4,200. Applica-

tions accepted until further notice. Those interested should communicate with Merit System Supervisor, P. O. Box 1911, Wilmington, Del., or State Board of Health, Dover, Dela.

Notice of an expected vacancy for an Industrial Hygiene Engineer in the Los Angeles County Health Department has been received. Those interested should communicate with Dr. H. O. Swartout, Acting County Health Officer, Los Angeles, Calif.

Tuberculosis Association in large eastern city is accepting applications for position on staff as health education secretary. Requirements: basic training in health education. Experience desirable. Should have ability in public speaking, radio, newspaper and visual education including sound motion pictures and exhibits. One month's vacation. Five day week with occasional work on Saturdays. Young man exempt from military service. Address Box K, Employment Service, A.P.H.A.

Announcement is made of the following examinations to be held by the State Personnel Board, Seattle, Wash., for positions in the State Department of Health and County Health Departments:

Position	Salary Range	
	Entrance	Maximum
Bacteriologist B.....	\$160	\$190
Laboratory Helper D...	120	140
Laboratory Assistant C	140	160
Laboratory Technician	140	170
District Public Health Officer V	380	440
Public Health Nurse B	160	190
Asst. Venereal Disease Investigator B	160	190
General Sanitarian A...	190	220
Milk Sanitarian A.....	190	220
Chief of Public Health Education	280	320
Senior Milk Sanitarian..	220	250
Obstetric Consultant VI	440	500
Pediatric Consultant VI	440	500
Senior Bacteriologist A	190	220

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

Physician, age 36, M.D., Iowa, Dr.P.H. Harvard, specializing in tuberculosis, seeks position as medical director of a sanatorium or a state bureau of tuberculosis. Exempt from military service. **A-476**

Physician, M.D. Yale, with private practice industrial medicine. Age 39 and draft exempt. Seeks opportunity as public health physician. **A-505**

Bacteriologist, 28, Iowa State College, draft immune, 3 years' experience public health laboratory. Experience in investigation and control activities on water, sewage and sanitation, as chemist and

bacteriologist and serologist in syphilis and enteric diseases. **L-465**

Physician, M.D. University of Arkansas, M.P.H. Harvard, experienced as county health officer. Age 35. Will consider position as city or county health officer or director of a bureau. **A-506**

Woman physician, well prepared in pediatrics, M.S.P.H. DeLamar Institute, Columbia University, 1943, seeks employment in the field of maternal and child health, preferably administrative in pediatrics. Excellent references. **A-507**

NEWS FROM THE FIELD

HEALTH DEPARTMENT FUNCTIONS IN CIVILIAN PROTECTION

The Office of Civilian Defense has published an *Operations Letter No. 131* on the Health Department in Civilian Protection for distribution to state and local defense councils. At the request of George Baehr, M.D., Chief Medical Officer of the O.C.D., the letter is reprinted herewith.

Organization

Local—Regulations No. 3 of the Office of Civilian Defense provides that the Staff Unit of the U. S. Citizens Defense Corps "may include the Health Officer, who shall advise the Commander regarding emergency measures for disease prevention. He may be assisted by his deputies, division chiefs, and sanitary inspectors." (Section 16 (d) (11) of Office of Civilian Defense Regulations No. 3, amended to August 1942.)

Accordingly, it is recommended that each Commander of the U. S. Citizens Defense Corps, who has not already done so, appoint the local Health Officer as a member of his staff, in order that emergency health and sanitation activities may be properly coordinated with all protective services of the U. S. Citizens Defense Corps. A Health Officer serving as Chief of the Emergency Medical Service need not relinquish that position. He may assign deputies to act for and assist him in direction of the Emergency Medical Service or in supervision of emergency health and sanitation activities, or both.

State—The State Health Officer has important responsibilities defined by law. The State Defense Council should obtain his guidance and leadership in developing the civilian protection health and sanitation program throughout the State. In some States, agencies such as the departments of agriculture, labor, and welfare also may have legal responsibilities for certain matters affecting health. In these States it may be desirable to appoint a Health and Sanitation Committee, composed of representatives of all such agencies, to arrange, in accordance with existing State law, for the fullest utilization of personnel and facilities for the protection of health.

Duties

The Health Officer, as a member of the Staff of the Citizens Defense Corps, should develop plans for prompt and appropriate action during and after air raids or other disasters to assure:

1. Maintenance of safe water, food, and milk supplies.
2. Sanitary disposal of sewage and putrescible wastes.
3. Sanitation at mass feeding centers, rest centers, casualty stations, billets, and other temporary facilities for war emergencies.
4. Control of communicable disease.

Planning should include the mechanism for mobilizing essential personnel during and following an actual emergency, as well as arrangements for immediate instruction of the public in emergency sanitary measures in event of disaster. The Health Officer should review the plans and inspect the facilities of other services of the Citizens Defense Corps in order to eliminate potential health hazards.

Membership in the U. S. Citizens Defense Corps

The Health Officer, his deputies (including deputized volunteers), division chiefs, and sanitary inspectors are eligible for membership in the Staff Unit of the U. S. Citizens Defense Corps to facilitate performance of their duties in maintaining sanitation after an air raid or other wartime disaster. In some communities the health department may be inadequately staffed to provide sanitary supervision and inspection services in a war emergency. Under these circumstances, the Health Officer may select volunteer health deputies with experience or training in the fields of public health, sanitary engineering, bacteriology, chemistry, and related fields and may recommend their appointment in the Staff Unit of the Citizens Defense Corps. Deputies may be assigned by the Health Officer to supervise and inspect emergency activities and facilities, such as disinfection of fractured water mains, pasteurization of milk, and preparation and handling of food at emergency feeding centers. Health department officials and volunteers, in order to become members of the Staff Unit, must complete training in accordance with Regulations No. 3.

The Health Officer may prescribe additional technical training for those under him after their enrollment as members in the U. S. Citizens Defense Corps.

HOME CANNED FOODS AND BOTULISM

In view of the fact that the Association office has discovered much interest in thoroughly approved means for the prevention of botulism and with special reference to the current Victory Garden Program, the following bulletin of the California State Department of Public Health is published herewith, because it has the approval of those with wide experience in this field, including Dr. Karl F. Meyer, the Director of the George Williams Hooper Foundation of the University of California.

"Home-canned vegetables, fruits, fish, meats, and animal products can be eaten without danger of botulism—a highly fatal poisoning—if simple precautions are observed.

- "1. Never eat home-canned vegetables, meat, or fish, even in tiny amounts, without first boiling the food for at least 15 minutes after removing it from the container. This must be done because it is not possible to tell that the food is capable of causing botulism by looking at it or smelling it. If the food is poisonous, even the tiniest amount may cause death.
- "2. If in doubt about fruits; remove them from the container and boil them. The odors of decomposition will warn you.
- "3. Never eat any canned food which shows mold growth or appears in any way to be abnormal such as having a bad odor or coming from a bulged container.
- "4. Do not feed canned foods suspected of being spoiled to poultry, pets, or other animals.

"Botulism is caused by a poison, produced under certain conditions by the *Bacillus botulinus*. This *bacillus* is a spore which is present in the soil. It is transferred from the soil to food products. It is so small that it can be seen only with the aid of a microscope.

"Fortunately the poison is produced only by the germination of the *Bacillus botulinus* and the *bacillus* germinates only in the absence of air. For this reason, raw foods and cooked foods that have not been canned do not cause botulism. The airless interior of a sealed can or glass jar provides the ideal

condition for the reproduction and growth of the *bacillus* and the consequent production of the poison.

"The spores of *Bacillus botulinus* can be destroyed by high temperatures. Botulism is prevented in canning by heating the food to a temperature above boiling. This temperature must be maintained for a sufficient length of time to permit the heat to penetrate to the very center of the contents of the can. The temperature which is necessary and the duration of the heating depend upon the density of the food and the rapidity with which the heat is conducted through the food and the container. The temperature and the heating time vary with different foods and different containers.

"Commercial canners in California are licensed by the State Board of Public Health and use methods prescribed by the Board. An inspector is present in the plant during the canning of any food capable of causing botulism.

"Housewives who own steam pressure cookers and who have the technical knowledge concerning proper temperatures, and the period of heating required for different foods and different containers, may use this method of canning with safety. The University of California, Berkeley, issues a very complete bulletin of instructions entitled Home Canning, Circular 276.

"Many people believe that botulism is only caused by eating home-canned string beans and olives. This is not true. Cases recorded by the California State Department of Public Health involve 32 kinds of foods, including 18 vegetables, six different meats and cheeses, three kinds of fish and five varieties of fruit.

Illness from botulism usually occurs from 24 to 48 hours after the food has been eaten. This is very different from ordinary food poisoning due to spoilage, which usually occurs from 2 to 4 hours after eating.

"The symptoms of botulism are also different from other food poisoning. They include muscular weakness, disturbances of vision, loss of ability to swallow and talk. The pulse is rapid and the temperature below normal. There is rarely any pain or symptoms of indigestion. Death is due to paralysis which makes breathing impossible. Call a doctor as soon as the first symptoms are noticed. Prompt medical care can sometimes save the life of the patient."

U. S. FEDERAL SUBSIDIES FOR NURSING EDUCATION PASSED

On June 15 it was announced that the Bolton bill to provide more nurses

for military and civilian war training service through subsidized training and the establishment of a uniformed nurse reserve had been signed by President Roosevelt. Representative Frances P. Bolton of Ohio who sponsored the bill indicated that the law would now provide for a student war nursing reserve which is expected to reach an enrollment of 65,000 by the end of June, 1944. Students will receive free tuition, maintenance, and uniforms, and from \$15 to \$30 a month from the Public Health Service. They must agree to serve either in the armed services or in emergency civilian jobs. Administration of the corps will be under the Surgeon General of the Public Health Service. Funds in the amount of \$65,000,000 a year are expected to be devoted to implement the program.

HARD OF HEARING CHILDREN PROJECT APPROVED IN CALIFORNIA

It has been announced that Governor Warren has signed two bills passed by the recent Legislature making available to the State Department of Health \$26,500 for the examination of children by trained otologists to detect hearing difficulties. Other funds were made available to the State Director of Education for consultant services in connection with the education of hard of hearing children in areas where these services are not otherwise available.

These bills were designed to make possible to children in small cities and rural districts the same services that are available to children who live in larger cities. The bills were sponsored by the California Committee for Hard of Hearing Children, of which Conrad G. Selvig of Santa Monica is Secretary.

NEW YORK STATE UNDERTAKES POSTWAR PLANNING PROGRAM

The New York State Legislature has established a Postwar Planning Commission which, in cooperation with the

Division of Sanitation of the New York State Department of Health and the State Superintendent of Public Works, now has under consideration water supply and sewage disposal projects, and a variety of other structures, including municipal refuse incineration plants. More than 139 proposed sanitary projects are at the present time being considered.

A feature of the New York scheme includes an appropriation to assist municipalities, school districts, and district corporations in meeting the cost of the preparation of such plans. For all projects that it approves the commission is authorized to allocate an amount equivalent to one-half of one per cent of the cost of the project for the preparation of preliminary plans and, if these are approved, it may allocate an additional sum up to one and one-half per cent of the cost of the project as its share of the expenditure for final detailed plans.

JOHN M. DIVEN MEMORIAL MEDAL

Health News announces that Earl Devendorf, Assistant Director of the Division of Sanitation of the New York State Department of Health and State Water Coördinator of the New York State Mutual Aid Plan for Water Service, has been awarded the John M. Diven Memorial Medal by the Medal Committee of the American Water Works Association "in recognition of the most outstanding service to the American Water Works Association last year." The presentation was made on June 17 at a dinner meeting conducted in connection with the war conference of the Association in Cleveland, Ohio.

In making the award the committee pointed out that "Mr. Devendorf originated the mutual-aid program on a fully coöperative basis, bringing into the work a large number of members of the Association who are water works

executives in the state. Participating with these water works executives have been many engineers of the New York State Department of Health, who, to the degree that they have contributed to the Mutual Aid program, share in the honor conferred upon the recipient of this award. The development of the Mutual Aid program in the water works field has been a conspicuous activity in many states and is, in effect, the most outstanding service and advancement in the field of the year."

IDAHO PUBLIC HEALTH ASSOCIATION

The following new officers were elected by the Idaho Public Health Association at its June 3rd Annual Meeting:

President—W. V. Halversen, Ph.D., Moscow
Vice-Presidents—Stuart Robinson, Gooding
 Mrs. H. J. Maughan, Preston
 Mrs. Emma Clouche, Twin Falls
 H. B. Yearsley, Pocatello
 Mrs. R. L. Brainard, Wardner
Secretary—H. C. Clare, Boise
Treasurer—Lucy M. Higgins, Boise
Representative on the A.P.H.A. Governing Council—L. J. Peterson, Boise

ARIZONA PUBLIC HEALTH ASSOCIATION

New officers of the Arizona Public Health Association were elected as follows at a recent meeting:

President—H. L. McMartin, M.D., Phoenix
President-elect—Mary E. Caldwell, Ph.D., Tucson
Vice-President representing Public Health Nursing Section—Hazel Kandler, R.N., Tucson
Vice-President representing Sanitarians—O. W. Fowler, Phoenix
Vice-President representing Clerks—Parma Branscomb, Phoenix
Vice-President representing Laboratory Section—Marion Stroud, Phoenix
Secretary-Treasurer—Fred M. Ashley, Phoenix

A.W.V.S. STARTS SAFETY PROGRAM

The American Women's Voluntary Services is extending its wartime activities to include a safety program to be

known as the Safety Plan. Home safety and accident prevention are its objectives. The program will be conducted through the local units of the American Women's Voluntary Services in full coöperation with local safety organizations and other organizations that sponsor safety educational activities, such as the Parent-Teacher Associations, women's clubs, the boards of education, health departments, etc.

The members from the local units selected for this work are urged to take the Red Cross Home Safety Course and the program will be centered upon the types of accidents most common in the particular locality.

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

The Seventh Annual Meeting of the Public Health Association of New York City was held at Hotel George Washington, New York, N. Y., May 12.

At the afternoon session the speaker was Elisabeth C. Phillips, R.N., Assistant Director of Field Practice, Henry Street Visiting Nurse Service. Her topic was "Great Britain in War Time."

At the dinner session the speaker of the evening was Professor Robert Hughes Parry, M.D., Medical Officer of Health of the City and Port of Bristol, England. Dr. Parry's topic was "Meeting the Wartime Health Problems of an English City."

The officers elected to serve until the Annual Meeting in 1944 were:

President: Leverett D. Bristol, M.D.
First Vice-President: Sol Pincus
Second Vice-President: Alfred E. Shipley, M.D.
Secretary-Treasurer: Frank Kiernan

Sol Pincus, Deputy Commissioner of Health of the City of New York, was continued as representative to the Governing Council of the American Public Health Association.

NUTRITION EXHIBIT OF CALIFORNIA ACADEMY OF SCIENCES

Robert C. Miller, the Director of the California Academy of Sciences, Golden Gate Park, San Francisco, has reported on the development of a nutrition exhibit built by the Academy partly from contributions made by the Northern California Public Health Association, and by the Western Branch of the American Public Health Association, which has been shown in Seattle, San Jose, Santa Barbara, Sacramento, Marysville and Palo Alto. Mr. Miller recently reported to Dr. Guy S. Millberry, Treasurer of the Western Branch A.P.H.A., that the contributions of \$420 toward the construction of this exhibit had been used by the Academy to supplement its own investment and to make possible an exhibit at the Western Branch meeting in 1942. Since June, 1942, the expenses of transportation of this exhibit have been paid by the agencies borrowing it. When the exhibit was not enroute it has been displayed in the Museum of the Academy in Golden Gate Park. The exhibit since its completion has traveled over 3,000 miles and at a conservative estimate has been seen by 150,000 people. It is available for showing throughout the western states.

Ann Wilson Haynes, Secretary of the Northern California Public Health Association, has reported that the Association has made its contribution to this exhibit from funds rebated to the affiliated society by the American Public Health Association. It is suggested that other affiliated societies which make definitive use of rebate funds will make their experiences available to the professions through the columns of the *Journal*.

DENTAL TRAINING FOR MEDICAL STUDENTS IN NEBRASKA

A program has been inaugurated at the College of Medicine, University of

Nebraska, to instruct medical students in aspects of dentistry from a public health standpoint. According to H. M. Wilbur, D.D.S., who is in charge, the fundamental aim is to help the medical student become aware of the dental problem and how this problem affects the practice of medicine. This program is carried out through the medium of lectures in which the student is presented with material to form a background for an understanding of the fundamentals of dental and oral pathology. This material is accompanied, expanded and fortified by opportunity for clinical observation in the dispensary and hospital.

The chief topic of discussion in the lectures is dental caries. Material is presented on dental anatomy, both gross and microscopic, tooth development, calcification and eruption, anomalies and deformities of the teeth, the clinical aspects of caries, factors influencing the localization of cavities, the epidemiology of caries, all as forming a background of the caries problem. A detailed discussion of the current theories of the etiology of caries is presented from a historical, experimental, and practical standpoint, and the details of the bacteriological examination of the patient's saliva as a diagnostic and prognostic procedure are included. The recent work on the influence of the association of fluorides in the drinking water on caries is discussed, together with other influences such as diet and nutrition, sunlight, and physical state.

The clinical exposure of the student is accomplished through assignments to the dental clinic in the dispensary where he observes examinations wherein the importance and significance of radiograms and bacteriological examinations are emphasized. He also observes routine dental procedures, such as prophylaxis, fillings, and extractions. An evaluation of the individual patient's dental status in the light of the medical

problem is made, both in the dispensary and in the hospital, so that the student may see the different aspects presented by ambulatory and hospitalized patients.

This program was made possible through the efforts of the Children's Bureau of the Department of Labor in cooperation with the Nebraska State Health Department. The dental director is a member of the Division of Maternal and Child Health of the State Health Department, which division is comprised of an obstetrician and gynecologist, a pediatrician, a nutritionist, a bio-chemist and a pediatric nurse. This unit works in close intercooperation, and the dental program is integrated with it in problems of maternal and child health. The clinicians are all full-time members of the teaching staff of the College of Medicine.

MARYLAND STATE PLANNING COMMISSION COMMITTEE ON MEDICAL CARE REPORTS

The Maryland State Planning Commission, of which Abel Wolman, Dr. Eng., Professor of Sanitary Engineering at Johns Hopkins University, is Chairman, has recently published the report of the Committee on Medical Care.

Among the conclusions and recommendations it is pointed out that in certain sections of Maryland some essential medical services are not available to the medically indigent. There has been a growing tendency for these persons to request medical care from state and county health departments and corresponding departments of welfare. Diagnostic and other medical services have been provided in some fields of medicine, especially tuberculosis, venereal, and mental diseases, by the state and county departments of health. At present there is no state or local department or agency legally responsible for making these services

available to the indigent, except in the limited fields of medicine with which state and county departments of health now concern themselves.

Among the recommendations it is proposed that a plan be adopted to provide medical care, including hospitalization, to the medically indigent, the program to be administered by the State Department of Health. The determination of the eligibility of applicants and the certification of them for care, as well as the payment of compensation to physicians and institutions, is to be a function of the state and county departments of welfare. It is proposed that the State Board of Health should establish a Council on Medical Care to formulate policies for the administration of the program. The Bureau of Medical Care should be established within the State Department of Health under a chief who should be a physician experienced in the field of medical care and appointed by the Director of the State Department of Health with the approval of the Council on Medical Care, serving on a full-time basis. The county health officer will administer the local program of the Council on Medical Care for the care of the medically indigent in homes, clinics and hospitals.

PROPOSED SOCIAL SECURITY ACT AMENDMENTS OF 1943

Senator Robert F. Wagner on June 3 introduced in the U. S. Senate the Wagner-Murray Bill, S-1161, which provides for a unified national social insurance system of new scope, consisting of a national system of public employment offices, old age and survivors' insurance, permanent disability insurance, lump sum death benefits, protection of the social security rights of men and women in military service, unemployment insurance, temporary disability insurance and maternity benefits, unemployment allowances upon

termination of military service, and medical and hospitalization insurance.

According to Senator Wagner the bill covers broadly the major economic hazards of average people throughout their lifetime—loss of income in time of unemployment, sickness, permanent disability, and old age. It assures medical care and hospital service for the American people "while protecting the free choice by the patient of doctor and hospital and the free choice of patient by the doctor and the hospital." It would increase the old age benefit allowances for workers and their families and extend coverage to 15,000,000 persons now excluded, such as farm workers and domestic servants, employees of non-profit institutions, and the independent farmer, professional and small business man.

According to Senator Wagner the bill would create a unified system of social insurance with one set of contributions, one set of records and reports, one set of local offices, making for a more efficient administration, reducing the number of reports and the cost to employers, and simplifying the entire program for workers, employers, and the public. The bill extends to all the members of the armed forces upon their return to civilian life all the phases of insurance protection, whether or not they were covered or had accumulated benefit rights in previous years. This includes a special unemployment allowance for 26 or possibly 52 weeks up to a maximum of \$30 per week, depending on the size of the family.

Section 11 of the bill is concerned with medical care and hospital benefits and sets up a federal system of medical and hospital insurance for all persons covered under old age and survivors' insurance and for their dependents. Each insured worker and his dependent wife and children would be entitled to the services of a phy-

sician who was a general practitioner and, on the doctor's advice, to specialist, consultant, and laboratory services, including x-ray, appliances, eyeglasses, etc., and necessary hospital care. According to Senator Wagner "the bill contains various provisions to assure that medical benefits will be the highest quality that can be made generally available, will promote personal relations between doctor and patient, will emphasize prevention of disease, and will be adapted to the needs and practices of the community in both rural and urban areas."

The Surgeon General of the U. S. Public Health Service would administer the technical and professional aspects of the program, with financial and social insurance relationships to be the responsibility of the Social Security Board. Hospital care is limited to 30 days a year, with a possible maximum of 90 days. All qualified hospitals are eligible to participate and all illnesses are covered for hospital care except tuberculosis or mental disease. Insured medical care covers all necessary service, but limitations may be fixed later if necessary. Medicines required outside the hospital would not be provided, nor would dental care, home nursing, private hospital rooms, and certain other services. The Surgeon General is authorized and directed to administer grants-in-aid to non-profit institutions and agencies engaging in research or in undergraduate or post-graduate professional education. Such grants could be made for projects showing promise of making valuable contributions to the education and training of persons furnishing medical and hospital, disability, and related benefits, or of making valuable contribution to human knowledge with respect to the cause, prevention, or methods of diagnosis or treatment of disease or disability. The maximum sum available each year for such grants-

in-aid would be 1 per cent of the total expended for all benefits, exclusive of unemployment insurance benefits, or 2 per cent of the amount expended for medical care and hospitalization benefits, whichever is less.

LOCAL HEALTH SERVICE—A NEW APPROACH

"After a decade or two of slow going, the movement for full-time public health service has rolled up such momentum in recent years that it is no longer fantastic to plan definitely to extend it to the whole population of the United States. Last summer the American Public Health Association set up a Subcommittee on Local Health Units under the Chairmanship of Dr. Haven Emerson. This committee has recently reported that more than two-thirds of the population is already provided with full-time health service under city, county, or state auspices. There remain, however, more than forty million people without such service. In their interest the committee has begun a systematic mapping of the whole country to discover what additional facilities are needed and how they can best be disposed.

"The committee suggests that population units of 50,000 should be able to support a full-time health officer and an adequate health department staff, including an average of one nurse for each 5,000 persons. On this basis the country could be blanketed with approximately 1,100 units.

"This preliminary plan needs to be refined and adjusted to geographical details. The committee is in correspondence with state health officers to this end, and expects to employ a small research staff for which the Commonwealth Fund has made an appropriation. The upshot of this consideration should be a sound plan of campaign for the distribution of health service. The American Medical As-

sociation and the American Public Health Association have both given official approval to the extension of public health service and the time is ripe for orderly and more rapid progress.

"The Fund is also sharing with the American Public Health Association, through an April appropriation and staff collaboration, in the task of revising methods of evaluating current health performance. A scheme has been devised whereby current experience can be compiled and reduced to convenient statistical indices for the guidance of health officers who wish to gauge their local achievement in comparison with prevailing standards. This device, when it is in full operation, will carry forward the service performed hitherto by the older Appraisal Form for Local Health Work."—From *News Letter* of the Commonwealth Fund, June, 1943.

CALIFORNIA STATE FEDERATION OF LABOR REQUIRES BLOOD TESTS OF UNION MEMBERS

Lawrence Arnstein, the Executive Secretary of the California Social Hygiene Association, San Francisco, has pointed out that the Executive Board of the California State Federation of Labor in its session in Hollywood on June 12 recommended to its affiliates that member unions require each applicant for membership to have a blood test made before admission into the union, the result of the test to be a matter of strictest confidence between the examining physician and the applicant, and under no circumstances to be revealed to the union or to the employer, and to have no bearing upon the applicant's admission into the union. The board further recommended that unions make arrangements with local public health departments to make tests for applicants for membership who do not wish to go to a physician in

private practice. It was further recommended that assistance from the California State Department of Public Health and local public health departments and the California Social Hygiene Association be secured in conducting an educational program among the entire union membership.

Assisting Mr. Arnstein, among others, was Arthur Painter of the San Francisco Health Department who is assigned by the U. S. Public Health Service as educator.

SANITATION EXPERTS ON INTER-AMERICAN HIGHWAY

The press recently announced that a Commission of Sanitation Experts which is studying conditions along the route of the inter-American highway had arrived in Guatemala. Dr. John R. Murdock, chief of the mission, is accompanied by sanitary engineers Charles C. Spenser, Herbert E. Hargis, and Walter Dashiell. Special attention is being given to drinking water supplies, drainage and tropical diseases existing near the highway.

IMPROVEMENT IN THE TEACHING OF TROPICAL MEDICINE IN THE MEDICAL SCHOOLS OF THE UNITED STATES AND CANADA

The Association of American Medical Colleges is conducting a program to improve the teaching of tropical medicine in medical schools. The program was developed at the request of the Surgeons General of the Army and Navy and has the coöperation of the Division of Medical Sciences of the National Research Council, the Pan American Sanitary Bureau, the Office of the Coördinator of Inter-American Affairs, the United Fruit Company, the Army Medical School, Tulane University, and the U. S. Public Health Service. It is supported financially by the John and Mary R. Markle Foundation.

The operation of the program is in the hands of a committee of the Association of American Medical Colleges consisting of Dr. Malcolm H. Soule, University of Michigan, Dr. Hiram W. Kostmayer, Tulane University, and Dr. Henry E. Meleney, New York University, Chairman.

The first phase of the program provided an opportunity for each medical school in the United States and Canada to send two members of its teaching staff to attend an 8 weeks' course in tropical medicine at the Army Medical School or Tulane. The first courses began January 4, 1943. By the end of August, 83 instructors from 59 schools will have taken advantage of this opportunity.

The second phase of the program consists of the distribution of teaching material to medical schools. The Army Medical School has established a Distributing Center for parasitological and pathological specimens. This center also gives advice as to sources of lantern slides and motion picture films. The Office of the Surgeon General has made available its epidemiological information concerning tropical diseases and medical services in tropical countries throughout the world. It has prepared maps showing the distribution of tropical diseases. This material is in process of publication through the coöperation of the National Research Council and the Markle Foundation and will be distributed to the medical schools and other interested agencies and individuals. The Office of the Surgeon General of the Army also has available a limited number of copies of *Circular Letter 33 SGO* entitled, "Treatment and Control of Certain Tropical Diseases," for the use of medical schools.

The third phase of the program consists of providing an opportunity to instructors from medical schools for a

month of practical experience in tropical medicine in Latin America, principally in the Central American countries. Two instructors from each medical school are offered this opportunity. Fifty-eight instructors from 43 schools have been accepted for this program. The first group of 8 individuals spent the month of June in Central America, and subsequent groups will go monthly until the program is completed. The program consists of 3 weeks' residence at a hospital of the United Fruit Company, followed by 1 week of observation of the program of the local field unit of the Office of the Coördinator of Inter-American Affairs in the respective Central American countries. It is possible that other such centers for practical experience may be utilized in the future.

MISS LUGINBUHL APPOINTED TO
A.P.H.A. STAFF

Martha Luginbuhl began her work July 6 as research assistant to the Subcommittee on Local Health Units under the Committee on Administrative Practice in the headquarters office, 1790 Broadway, New York, N. Y. The subcommittee is under the Chairmanship of Haven Emerson, M.D., and is developing a plan for the extension of local health services to all parts of the United States, as outlined in the April issue of the *Journal*.

Miss Luginbuhl most recently has been statistical supervisor in the National Headquarters, U.S.O. She was a statistical assistant in connection with two studies of the Research Bureau of the Welfare Council, New York, N. Y., on a Health Inventory of New York and Chronic Illness in New York City. Formerly she was Director of Statistics, Records and Information in the United Hospital Fund of New York and was on the staff of the Public Health Relations Committee of the New York Academy of Medicine.

CLIFFORD W. BEERS DIES

Clifford Whittingham Beers, founder and secretary of the National Committee for Mental Hygiene and the American Foundation for Mental Hygiene, and a man internationally known in his field, died on July 9 in Providence, R. I., at the age of 67. Mr. Beers was best known for his autobiography *A Mind That Found Itself*, which was published in 1908, representing his own experience of a mental break. In 1908 he founded the Connecticut Society for Mental Hygiene, the first organization of its kind, which was followed by the establishment of similar organizations in about 25 states. The National Committee was founded in 1909.

Born in New Haven in 1876, Mr. Beers was graduated from Sheffield Scientific School, Yale University, in 1897. Yale conferred an honorary M.A. degree on him in 1922. At that time President Angell said that it "was for indomitable courage and devotion in turning to the enduring benefit of mankind experiences that have driven most sufferers to silence and seclusion."

Mr. Beers in 1928 founded the American Foundation for Mental Hygiene and was organizer and Secretary General of the First International Congress for Mental Hygiene, held in Washington in May, 1930. The second International Congress for Mental Hygiene in Paris in 1935 was also organized by him. In 1930 he had founded and become secretary of the International Committee for Mental Hygiene. The following year he established and became secretary of the International Foundation for Mental Hygiene.

While a student at Yale an older brother of Mr. Beers had been fatally stricken with epilepsy and fear that a similar fate awaited him was experienced with increasing force until he suffered a mental breakdown in 1900. An attempt to take his own life was followed by confinement in institutions

for the insane for three years. In spite of his surroundings his reason gradually returned and he resolved to do what he could to correct the evils of the age-old system of caring for the mentally ill. He even voluntarily provoked commitment to the violent ward of one hospital in order to gain first hand knowledge of the worst conditions that prevailed. After his release from confinement in 1903 he entered business life, but early decided to sacrifice his right to privacy as to his own experiences and, through the medium of a book, to lay bare to the world the abuses he had endured and to focus public attention on the problems of the care and treatment of that class of unfortunates in whose behalf he felt it his peculiar right and duty to speak.

DR. L. T. WEBSTER, EPIDEMIOLOGIST, DIES

Dr. Leslie T. Webster, a member of the Rockefeller Institute for Medical Research, who was known especially for his work in epidemiology, died in Scarsdale, N. Y., on July 12 of a stroke, at the age of 48.

Born in New York, Dr. Webster graduated from Johns Hopkins Medical School in 1919, following which he joined the staff of the Rockefeller Institute, becoming a member in 1934. Dr. Webster was largely responsible for the establishment in this country of the science of experimental epidemiology. He developed colonies of mice and other animals and watched the spread of communicable diseases through them. More recently he carried on extensive researches on rabies, devising tests for early diagnosis and for determining the potency of anti-rabic vaccines. Dr. Webster joined the American Public Health Association in 1935 and became a Fellow in 1940.

PERSONALS

Central States

M. BERNETA BLOCK, M.D., Director of

the Alger-Schoolcraft Health Department, with headquarters in Manistique, Mich., has accepted a position as Director of the Maternal and Child Health Service of the Territory of Alaska, with headquarters in Juneau. Prior to her appointment in February as Acting Director of the Manistique health unit, Dr. Block had been Regional Consultant in Maternal and Child Health in Lansing.

G. HOWARD GOWEN, M.D., PH.D.,* formerly associated with the Chicago Department of Health and the University of Michigan School of Public Health, entered military service in July, 1942, and is now serving as Major in the Medical Corps with the First Medical Laboratory in North Africa.

FREDERICK C. HANEY, M.D., has been named Commissioner of Health of Watertown, Wisc., succeeding HARVEY G. E. MALLOW, M.D., who has been commissioned a First Lieutenant in the U. S. Army Air Force.

HUGO V. HULLERMAN, M.D., M.S. P.H.,* has resigned as Deputy Commissioner of Health in the Peoria, Ill., Department of Health to assume duties on July 1 as Chief of the Division of Maternal and Child Hygiene with the Illinois Department of Public Health in Springfield.

COLONEL EDGAR ERSKINE HUME, M.C., U.S.A.,* has been announced as Chief American Health Officer for The Allied Military Government of Occupied Territory, in the organization attached to the United States Seventh Army in Sicily. Dr. Hume was recently at the Winter General Hospital, Topeka, Kans.

PHILIP D. MCGINNIS, M.D., has been appointed Health Officer of Joliet, Ill.

REUBEN F. REIDER, M.D., D.P.H.,† Passed Assistant Surgeon, Reserve, serving in Illinois on loan from the

* Fellow A.P.H.A.

† Member A.P.H.A.

U. S. Public Health Service, is the Illinois District Health Superintendent for the Counties of Coles, DeWitt, Douglass, Edgar, Macon, McLean, Moultrie, and Platt, with headquarters in Decatur. Dr. Reider replaces WILLIAM M. TALBERT, M.D.,† of Decatur, who has been granted a military leave from state service to enter the U. S. Navy.

FRED O. TONNEY, M.D.,† formerly of the Chicago Health Department and more recently of the Delta County Health Unit, Escanaba, Mich., has been appointed Health Director and Research Consultant to the Toledo Scale Company, at Toledo, Ohio, under a research grant from the Company to the Toledo Health Department.

JOSEPH D. WARRICK, M.D., has been appointed Health Officer of Sharon, Wisc., to succeed L. C. Kief.

EARL M. WATSON, M.D., Health Officer of Cass County, N. D., has been appointed Health Officer of Fargo, succeeding ELVIN L. SEDERLIN, M.D.,† who resigned recently to become Regional Health Officer of Valley City.

Eastern States

JAY I. BOXER, M.A., began work on July 1 as a member of the community health education staff of the Onondaga Health Association in Syracuse, N. Y. Mr. Boxer has served for the last 6 years as social investigator in the Welfare Department of Suffolk County, New York. The association's program covers tuberculosis, social hygiene, and several other sectors of the health field.

LEVERETT D. BRISTOL, M.D., DR.P.H.,* of Montclair, N. J., has been named to succeed J. LYNN MAHAFFEY, M.D.,† of Camden, as State Director of Health of New Jersey, for a term

of 4 years. Dr. Bristol is Health Director of the American Telephone and Telegraph Company, in New York, N. Y.

MATTHEW A. BYRNE has been appointed Secretary of the New York City Department of Health, to succeed FRANK A. CALDERONE, M.D., M.P.H.,* who recently was appointed Deputy Health Commissioner. The appointment was made on the 40th anniversary of Mr. Byrne's service in the Department. In his new position he will supervise the administrative activities of the department and will continue as a member of the personnel board.

WALTER CLARKE, M.D.,† Executive Director of the American Social Hygiene Association, New York, N. Y., has been appointed Clinical Professor of Public Health Practice at Harvard University, Cambridge, Mass. For the past 3 years, Dr. Clarke has served as a Lecturer, in the Harvard School of Public Health, on public health administrative practice as applied to the control of syphilis and gonorrhea.

ALFRED L. FRECHETTE, M.D., M.P.H.,† Secretary of the New Hampshire State Board of Health, Concord, has been called to active duty with the U. S. Public Health Service for duties in North Africa. MARY M. ATCHISON, M.D., M.P.H.,† Director of Divisions in the State Board of Health, has been appointed Acting Deputy Secretary.

MIRIAM R. HAHN, M.P.H.,† of Hamden, Conn., who completed her course at Yale in 1943, has been appointed Director of Health Education in the Kern County Department of Health, Bakersfield, Calif.

CHARLES S. MCKINLEY, M.D., of Scotch Plains, N. J., has been appointed Director of the Bureau of Industrial Hygiene in the West Virginia State Department of Health,

* Fellow A.P.H.A.

† Member A.P.H.A.

on the recommendation of the U. S. Public Health Service. He succeeds JOHN W. CROSSON, M.D., who recently resigned to become Industrial Consultant for Sharp & Dohme, of Philadelphia, Pa.

RICHARD NAUEN, M.D.,[†] recently of Ray Brook, N. Y., has been appointed Tuberculosis Control Director in the Cattaraugus County Department of Health, Olean, N. Y.; and in charge of the Rocky Crest Sanatorium, succeeding E. K. RICHARD, M.D., who has resigned to enter private practice.

DR. ELMER H. STOTZ, Director of the Chemical Laboratory at McLean Hospital, Waverly, Mass., and a member of the teaching staff in biochemistry of the Harvard Medical School, according to *Science*, has been appointed by the Board of Trustees of Cornell University as Professor of Agriculture and Biochemistry and Head of the Division of Chemistry at the New York State Experiment Station at Geneva, N. Y. The appointment becomes effective on August 1. Dr. Stotz succeeds DR. DONALD K. TRESSLER,* who resigned early in the year to enter the industrial field.

HAROLD C. STUART, M.D.,* Assistant Professor of Pediatrics and Child Hygiene of the Harvard Medical School and the Harvard School of Public Health, Boston, Mass., has been interned with other Red Cross personnel and diplomats and was recently at Baden Baden, Germany. Dr. Stuart went to Europe for the American Red Cross to serve as medical director of relief activities in unoccupied France and Switzerland. He was in Marseilles ready to leave for the United States in November, 1942, when the African campaign began and has since been interned.

THOMAS M. THOMPSON, M.D., M.P.H., of Philipsburg, Pa., District Medical Officer for District No. 9, consisting of Clearfield, Clinton, and Centre Counties, has been transferred to District No. 4, composed of Bucks and Montgomery Counties, with headquarters in Norristown. GEORGE R. GOOD, M.D., of Altoona, District Medical Officer for District No. 10, including Huntingdon, Blair, and Cambria Counties, will have temporary charge of District No. 9. Dr. Thompson succeeds the late HOWARD W. HASSELL, M.D., of Bridgeport.

Southern States

MINYARD D. INGRAM, M.D.,[†] of Dresden, Tenn., Health Officer of Weakley County for 14 years, has resigned to accept a similar position in Gibson County.

FRANCES C. MONTGOMERY, R.N.,* who since 1936 has been Director of the School of Public Health Nursing in the College of William and Mary, Richmond, Va., has resigned and will make her home in Florence, Colo. Previous to her service in Virginia, Miss Montgomery was Director of the Bureau of Public Health Nursing in the Alabama State Department of Health, Montgomery.

ROSCOE ROY SPENCER, M.D., Medical Director, U. S. Public Health Service, who recently has been serving as Assistant Chief of the National Cancer Institute, Bethesda, Md., according to announcements, has been appointed Chief of the Institute effective August 1. Dr. Spencer will succeed DR. CARL VOEGTLIN, who is retiring.

BRIGADIER GENERAL JAMES STEVENS SIMMONS,[†] A.U.S., Director of the Preventive Medicine Division, Office of the Surgeon General, U. S. Army, has recently received the honorary degree of Doctor of Science from

* Fellow A.P.H.A.

† Member A.P.H.A.

Duke University, Richmond, Va., at its commencement exercises.

Western States

E. L. BERRY, M.D., M.S.P.H.,† Director of the Idaho State Department of Public Health since February, 1940, has been appointed Superintendent of the State Hospital North, at Orofino, Ida., effective June 1. Dr. Berry will continue to serve as Director until a successor is appointed.

EARL H. COLEMAN, M.D.,† has been appointed City Health Officer of Fresno, Calif., to succeed the late CARLETON MATHEWSON, M.D. Dr. Coleman will serve on a part-time basis.

CONCESSA L. CRAVIOTTO, M.D., has been appointed Health Officer of Oroville, Calif., succeeding CHARLES BENNINGER, JR., M.D.

DONALD G. EVANS, M.D., DR.P.H.,* State Health Officer of Washington, has resigned to enter the private practice of pediatrics in Seattle, effective June 1. Dr. Evans is succeeded by LELAND E. POWERS, M.D., M.S.P.H.,† Health Officer, Tacoma, Wash.

C. R. FARCHER, M.D., M.P.H.,* Health Officer of Vancouver, Wash., has resigned and has been appointed Health Officer of Tacoma, succeeding LELAND E. POWERS, M.D., M.S.P.H.,† who becomes Washington State Health Officer.

JAMES L. FAULKNER, M.D., has replaced RUSSELL G. FREY, M.D., as Health Officer of Red Bluff, Calif.

DEAN ELDON HART, M.D., of Oakland, Calif., was appointed Health Officer of Emeryville, Calif., succeeding CHARLES NEWELL MELL, M.D., of Oakland.

DR. RALPH R. PARKER, Director of the Rocky Mountain Laboratory of the

U. S. Public Health Service, Missoula, Mont., has recently had the Doctorate of Laws conferred upon him by the Massachusetts State College, Amherst, Mass.

CURTIS W. WILDER, M.D., of Lewistown, Mont., has been named Health Officer of Fergus County, to succeed the late CHARLES C. WALLIN, M.D., of Lewistown. Dr. Wallin held simultaneously the position of County Health Officer and Lewistown City Health Officer and full-time School Physician. The two latter posts had not been filled at the time of this report.

Puerto Rico

GUILLERMO ARBONA, M.D., M.P.H.,* formerly in charge of the training of staff at the Rio Piedras Unit of the Puerto Rico Department of Public Health, was appointed in April head of the Department of Public Health in the School of Tropical Medicine at San Juan, which is operated coöperatively with Columbia University, New York, N. Y. Dr. Arbona is Secretary of the Puerto Rico Public Health Association.

Deaths

CLIFFORD WHITTINGHAM BEERS, founder and Secretary of the National Committee for Mental Hygiene and the American Foundation for Mental Hygiene, New York, N. Y., died on July 9, in Providence, R. I., at the age of 67.

GILBERT T. CREECH, D.V.M., since 1912 Veterinary Pathologist in the Division of Pathology of the U. S. Department of Agriculture, Washington, D. C., died on June 2, at the age of 63.

DR. HARRY B. MELLER, formerly Chief of the Pittsburgh Bureau of Smoke Regulation, 1920 to 1938, and Managing Director of the Mellon Institute Industrial Hygiene Founda-

* Fellow A.P.H.A.

† Member A.P.H.A.

tion, Pittsburgh, Pa., from its organization to his resignation in September, 1942, died June 27, 1943, at the age of 65. Dr. Meller joined the Association in 1930 and was a member of the Engineering Section.

LESLIE T. WEBSTER, M.D.,* of The Rockefeller Institute for Medical Research, New York, N. Y., died July 12, at his home in Scarsdale, N. Y., at the age of 48.

The Child as a Wartime Problem

ROBERT HUGHES PARRY, M.D., F.R.C.P., D.P.H.*

Medical Officer of Health for the City and Port of Bristol, England; Professor of Preventive Medicine, University of Bristol

ONE of the instincts we admire most in an animal is the one whereby the parent protects its young. There are no dangers which it will not face to guard them. This instinct is highly developed in the human race and upon this foundation has been built our social and medical effort to prevent wastage of young life. Some would say that our success in this direction is a measure of our state of civilization. I firmly believe so.

This war has taught us the importance of pooling our resources—I am thinking here not of nations, for which it is equally true, but of an old city of nearly half a million people in Great Britain, Bristol, and of the 110,000 families in that city. If they had never known it before, they discovered early in the war how dependent they were upon one another, how little they could depend upon their individual instincts and resources and how much strength there is in unity. This city, between June, 1940, and June, 1941, went through more than 500 "alerts." To the inhabitants of a target area at that

time, an "alert" meant a good deal of gunfire, indistinguishable in the dark from the sound of exploding bombs, and the possibility, at any moment, of a high explosive or incendiary bomb falling somewhere near. It is of the efforts of that community under the guidance of the State to protect its young, that I would speak to you. The measure of success attained will be fully written when this war is over, but I can say here, as a guide to you, that the infant mortality rate for 1942, after more than three years of war, after many parents and more homes had been destroyed or broken up, was one of the lowest in the history of the city and was under 40 per 1,000 live births.

The Lord Mayor of Bristol, 1940–1941 (Alderman T. H. J. Underdown) has written a brief account† of the blitzed City of Bristol and, for a description of a raid, I cannot do better than to quote from this record:

"The 24th was a typical November [1940] day of dull leaden skies with a light mist towards sunset. As darkness fell, the alert was given and by 6:30 the skies over the

† Bristol Under Blitz: The record of an ancient City and her people during the Battle of Britain, 1940–1. Bristol: J. W. Arrowsmith, Ltd., 1942.

centre of the city were brightly lit by flares dropped from enemy 'planes. Then the fiery attack was let loose with utter ruthlessness. Showers of incendiary bombs kindled and spread the conflagration. High explosive bombs whistled and screamed to earth. Many were of extremely large calibre and spread the raging fires from building to building until whole streets were ablaze. The flames appeared as one huge fiery furnace leaping high into the air and giving an intensity of daylight over a great part of the City. The scene presented a veritable volcanic cataclysm. Crashes of high buildings and the volumes of flame, as castellated church towers carried the fires to greater heights, added a touch of grandeur to this inferno of terrorism. Men, afar off, scores of miles distant, gazed with wonder upon the illuminated skies as though peering into a mirror to learn the fate of a blitzed city.

"But while Bristol burned her people were bravely fighting. The Regular Police Fire Brigade led the van and was more than extended even with the support of 1,000 Auxiliary Fire Service men, ninety per cent. of whom responded to the call of duty within thirty minutes of the air-raid warning. Soldiers and naval men also co-operated splendidly. The men fought a great fight against overwhelming odds. During the first hour 70 fires were reported, mostly in the centre of the City. Every available appliance of the fire-brigade was brought into operation throughout the night and well on into the following day. Firemen were frequently diverted from their fire-fighting to save the lives of citizens. In this rescue work one officer faced the task of saving from a Home 35 elderly women, many of whom were invalids. Another diversion involved the evacuation of 60 horses from their stables. But the men fought on, several paying the supreme sacrifice on the altar of duty.

"Damage to the mains caused a failure of water supply. The reserve water from tanks and reservoirs was soon exhausted. There remained the supplies from the Avon and the harbour with the use of fire-floats. Meantime, assistance had arrived from other areas. The Bristol Fire Services were reinforced by 77 Fire Brigades from neighbouring counties, with an addition of 20,000 feet of hose from Cardiff, Newport, Bournemouth and Plymouth.

"Air-raid Precaution Wardens and Fire Watchers, both men and women, coped with a deluge of thousands of incendiary bombs, often preventing the raiders from finding their targets in many parts of the City. Of these

brave wardens 19 men, 3 women and 2 messengers lost their lives. Other citizens, even children, bravely extinguished incendiary bombs which had fallen upon homes, churches and other valuable properties.

"At the centre the communication services of the A.R.P. functioned efficiently during the early stages of the raid. Reports came in from all the depots promptly, followed by action. But when the lighting failed the wardens and their staff were greatly handicapped. Graver danger soon threatened when fires spread from Union Street to premises adjacent to the A.R.P. Central Control. When the relentless flames quickly set a part of the Control ablaze a section of the staff was sent to the Emergency Control. Just as the remainder were about to set out a message was received that the fire at the Museum had spread to the University and that water in the basement was already inches deep. Faced with a terrible alternative, the A.R.P. Control bravely carried on at Central Control for over an hour, although the back and upper part of the building was in flames. With coolness and courage they held on at their posts of duty. One girl telephonist answered an enquiry and then added with a cheery voice, 'I'm afraid I can't say any more now. The flames are all around me!' Evacuation became inevitable. Then they made a hasty transfer in private cars and on foot through the streets of their burning and bombed city to the City Engineer's Office in Queen Square. There they functioned with improvised equipment and restricted accommodation through the remainder of the night."

"The Utility Services were greatly dislocated. In wide areas of the City the water supply was either totally cut off or at such low pressure that the higher levels could not be normally supplied. Water carts, both civic and military, conveyed adequate supplies for domestic use. Gas, electricity and the telephone system failed over many parts of the City. Dislocation of the sewerage system presented a difficult problem. A large number of unexploded bombs added to the difficulties of complete and prompt restoration of these public amenities. But with surprising promptitude the 'severed arteries' were restored. Efficient assistance was given to Bristol's reserve of labour by gangs from other towns and by the military forces. The Royal Engineers and Infantry rendered valuable help in demolition of dangerous ruins, site and street clearance, traffic control and diversion and first-aid repairs to houses.

Within a few days 2,000 men were engaged in repairs on a large number of the 10,000 houses damaged in the raid."

It may be said that there is no house in Great Britain which can be considered to be 100 per cent safe from air attack. It is not intended in this paper to discuss the effect of this upon morale, either of the people at home or of the fighting forces away from home, but one may say in passing that the justice of our cause has proved to be a remarkable stimulant in my country.

The appearance of enemy bombers near our homes made us consider:

A. THE SAFETY OF OUR CHILDREN

When children are at home their safety is bound up with that of the other occupants of the home. Our experience has been that the home, the ordinary brick cottage without strengthening and even without special protection inside it, is a remarkably safe place during the heaviest air raids. At a time when we did not have the various types of shelters that are now available, whole families emerged from their ruined house very little the worse for their experience. Casualties, especially among children, were far fewer than we expected. I need not tell you that the parents did all in their power to give the best protection they had to their children. This was brought out very clearly in an analysis made of casualties following one heavy night's raid. At that time about 50 per cent of the population had air raid shelters of some kind. On that same night nearly 10,000 houses were damaged, more than 400 beyond repair.

It is noteworthy that, whereas children under 16 years of age form about 20 per cent of the normal population of the city, on this occasion only 6 per cent of the casualties were children (see Table 1).

After standardization for age and sex distribution one could say that:

TABLE 1

	Males	Females	Children under 16	Total
Killed	117	90	22	229
Seriously injured	110	51	13	174
Lightly injured	189	49	10	248

1. Men took nearly double the risk of women and over three times the risk of children of being killed.

2. Men took nearly three times the risk of women and six times the risk of children of being seriously injured.

3. Conversely, were it possible for men and women to take the same precautions to protect themselves as were available for children, it may be assumed that the following casualties would have been avoided.

	Males	Females
From death	2/3	1/2
From serious injury	5/6	1/2

In order to protect children during the daytime when they were attending school, shelters were erected at all schools in the city. In schools where there was sufficient accommodation available, strengthened basements or trenches, or underground steel shelters were the types used. In schools lacking the necessary space for this, brick surface shelters were erected in the school grounds. Accommodation has been provided in school air raid shelters for 45,452 children at a cost of about £250,000.

The great difficulty, of course, in regard to schools, is the question of dispersal of the children and, in order to avoid casualties, we lay great stress upon this point. In no instance will a shelter erected at a school hold more than 50 children (equivalent in superficial floor space to 33 adults); even then it would be a catastrophe if one of these places received a hit.

We have no remedy against the solitary bomber flying behind cover of the clouds and dropping a bomb on a crowded school without warning of any kind.

B. EFFECTS OF AIR RAIDS

With regard to the general effect of

"alerts" and air raids upon children, particularly upon the school child and upon his life, some interesting papers have been published.

In February, 1941, Miss Dunsdon, our educational psychologist, made a survey of 8,000 school children to assess the evidence of strain following air raids and she found that 4 per cent (300) showed some signs of strain, either purely psychological or psychosomatic. One hundred and twenty was the figure she gave as suffering from psychological symptoms. These occurred twice as frequently in the 5-7 year group of children as in the 11-14 year group in whom psychosomatic disturbances were more frequent. Considering the severity of the raids, it shows how remarkably stable children are. The Deputy Director of the Bristol Child Guidance Clinic—Dr. Frank Bodman—has published a paper under the title "War Conditions and the Mental Health of the Child" in the *British Medical Journal* of October 4, 1941.

To those of us who have had an opportunity of observing the reaction of children to air raids, it has become quite clear that not only have the children stood up to raids in a quite remarkable manner, but they undoubtedly have been an example to the grown-up people. I would go so far as to say that the children of my city have contributed a good deal to public morale by their high spirits and their refusal to be intimidated by raids. I remember hearing a rather charming story of two children in an air raid shelter in one of our worst raids, when a girl aged 8 was heard to say to her small brother aged 6: "If you don't keep quiet, you won't hear a bomb fall."

C. INTERRUPTION OF EDUCATION

A report upon the interruption of the education of the children of Bristol was prepared for his committee by G. E. Sylvester, Chief Education Officer.

Here are some extracts from his report:

"In the early days of raiding of Bristol, there was considerable interruption of education and the local authority was extremely cautious in bringing large numbers of school children together and exposing them to possible risks. All Bristol schools were closed on the outbreak of war, but were reopened for children over 7 years of age within about a fortnight; after another fortnight children between 5 and 7 were admitted, and a fortnight later children under 5 were readmitted to nursery schools and nursery classes. Because of shortage of shelter places, a double-shift system operated for a time at the end of 1939 and education was, therefore, on a half-time basis. Attendance at school was voluntary from the beginning of the war until May, 1940, when compulsory attendance was reintroduced. Even after the double-shift system was abolished, many children only attended part time because there was not sufficient shelter accommodation available.

"In the latter part of 1940, Bristol school children spent considerable periods of school hours in air raid shelters under conditions which made it next to impossible to carry on any form of education. In September, 1940, for example, during the battle of Britain, out of 21 school days, 'alerts' were sounded on 18 days 29 times and the actual duration of 'alerts' during school hours was 13 hours out of approximately 115 hours. In addition we should remember that considerable time was spent in getting to and from shelters and the excitement unsettled the children.

"The effect of long night raids of the winter of 1940 should also not go unnoticed. Children were tired the next morning, and if they came to school at all they were not in a fit condition to take part in the rigorous routine of school life. The difficulty

was partly met by an alteration of school hours and the later opening of schools in the morning, but there is no doubt that this factor of night raids also constituted an interruption of education."

D. JUVENILE DELINQUENCY

This leads me to mention the problem of juvenile delinquency.

1. *Nationally*—In the first twelve months of the war there was an increase nationally of 41 per cent in the number of children (under 14) found guilty of indictable offenses, and an increase of 22 per cent in the number of young persons (14–17) found guilty of such offenses. In the same period the increase of delinquency in the age group 17–21 was not more than about 5 per cent, and in the group 21 and over there was a decrease of about 2 per cent.

The increase in the volume of juvenile delinquency may be traced to a number of causes, including the absence of fathers on military service, the taking up of war work by mothers, the breaking up of home life owing to evacuation, the interruption of education owing to evacuation and the closing of schools in the early stages of the war, and the increased earnings of young people accompanied, for many of them, by a reduction in the facilities available in youth organizations, at any rate in the early days. In addition to these easily discernible causes, it would be unwise to ignore the effect of the excitement and unsettlement of the war, especially on adolescent boys.

2. *The local position*—In Bristol, the number of children found guilty of indictable offenses increased by 45.5 per cent in the first year of war, and the number of young persons by 5.5 per cent. There was a further rise in the second year of the war, but in 1941 there was a notable drop in the number of boy delinquents (both children and young persons).

From Mr. Sylvester's report:

"We do not wish to appear to minimize the seriousness of the increase in the volume of juvenile delinquency in the first two years of war, but we think it necessary to keep a sense of proportion in the matter. Close attention to the problem is very necessary, but its extent sometimes tends to be exaggerated and to be the subject of hasty generalisations which are not supported by the facts. The largest number of children and young persons found guilty of indictable offences in any of the last four years is 338 (1940–41). We estimate that the total number of children and young persons living in Bristol between the ages covered by these categories is about 50,000 and it will be seen that the proportion of these committing offences is not large in relation to the total number in the age group concerned. Moreover, the outlook for the young offender in the long run is very good, for statistics show that 90 per cent of the boys and girls who give trouble become useful citizens in life."

During the period of the war there has been in my city and, indeed, in Great Britain generally, a very great increase in what we call the "Youth Service." The Board of Education and the local education authorities have encouraged youth organizations, and in Bristol the number of boys in the membership of youth organizations has increased by nearly 200 per cent during the war, and the number of girls by more than 100 per cent. At the present time, more than 50 per cent of these boys and girls between 14 and 18 years of age are members of some form of approved youth organization. The movement is largely influenced by the ideal of service to the community and to other people. It is not too much to suggest that the decrease in the amount of juvenile delinquency at these ages during the war period can quite

definitely be associated with the growth of the Youth Service movements.

Our Child Guidance Clinic played an active part in sorting out cases and advising upon particularly difficult ones throughout this period. For their experience, I would refer you to a paper published in the *Lancet* of November 8, 1941, by Dr. Bodman and Miss Dunsdon under the heading "Juvenile Delinquency in Wartime."

Some of the local factors which have played a very important part in this question of juvenile delinquency, which I should like to mention, are the following:

About 30 schools were partially or completely put out of action. This affected more than 7,000 places of accommodation. In addition, several schools were temporarily put out of service.

Many of our younger male members of the teaching staff (189) are serving with the Forces—the fact of this large withdrawal of men teachers on the disciplinary training of boys must have considerable effect, particularly as these teachers were active in promoting out-of-school organized games and sports and were making an important contribution to the teacher/leader development of youth welfare centers, boys' clubs, and other youth organizations.

For many reasons too, the parents' outlook toward regular attendance in school seems to have been modified. One can well understand this mental attitude of many parents in view of the relatively less importance of education as compared with the safety and other matters in the wartime life of the child.

When all these facts are taken into consideration, it can be said that juvenile delinquency is not an outstanding result of war and air raids upon the City of Bristol.

E. EVACUATION

Bristol became an evacuation area at the end of January, 1941, and the first parties of children were evacuated about the middle of February. This followed urgent representation from the local authority's committees to the Ministry of Health. By that time we

had been having severe air raids—a total of 28 from June 25, 1940 (which was the first upon Bristol), until the end of February, 1941, with a large number of casualties.

AIR RAIDS ON BRISTOL, JUNE 25, 1940, END FEBRUARY, 1941

Dead	711	} 1,521	} 2,780
Seriously injured	810		
Slightly injured	1,259		

I can only speak of this problem of evacuation from the point of view of the evacuating authority. There is no doubt that this is one of the greatest social experiments ever tried in Great Britain, and the full story of the effect upon the evacuated children and upon the homes in the reception areas and upon the people in those homes remains to be told.* As an evacuating authority we had the great problem of trying to get large numbers of children transported in short spaces of time to less vulnerable localities.

I may be forgiven here for trying to give you a brief account of life in the city for several months preceding evacuation, when the city was subjected to severe bombing.

During these days shelters were extensively used. *Public shelters*, either brick surface shelters or trench shelters in public parks, etc., which were open for use to any member of the community, accommodated approximately 10,000 children every night. There was some overcrowding in this type of shelter in the early days of raiding and the children lost much sleep. This probably affected their education more than their health, for no great increase in any infectious illness was reported. When bunks were provided a number of mothers with children attended regularly every night whether an "alert" was sounded or not because they feared that if they did not stake out a regular claim to bunks and occupy them with

their families each night they might find, on arriving after the "alert," that their usual place had been taken by a stranger who had got there first.

The communal type of shelters, mostly brick surface shelters allocated to certain numbers of houses, or streets accommodated another 10,000 children, but only a small percentage of this number used them every night. Communal shelters were private, and allocated to groups of families. They were conveniently situated near the homes of these families and were only used to any large extent during actual raids.

Small shelters of the "Anderson" type were used by a large part of the population. In many housing areas this type of shelter was in common use, and it was the practice in these areas to put children to sleep in them regularly each night at "black-out."

Under these circumstances, the routine of the home had been greatly disturbed, the "alerts" usually sounded in the early evening, just at bath time. This part of the child's daily routine, therefore, either completely disappeared or was very much modified. The expected results followed—head vermin became prevalent. The problem of head vermin was very much eased by the use of Lethane (384 special). This is a mixture of organic thiocyanates in 50 per cent of highly refined petroleum oil. (The principal toxic ingredients are the beta-thiocyano-ethyl esters of a mixture of higher fatty acids and beta-butoxy-beta thiocyanodiethyl ether). It is strongly insecticidal and has no toxic effects for the users. Of great value for all types of infestation, it has been found very effective in the treatment of pediculosis capitis and for this purpose is prepared with liquid paraffin as *Lithane Brilliantine*. This preparation is massaged into the scalp thoroughly and the hair is combed twice daily for a week, using a fine steel comb. Lice are killed instantaneously and the worst

cases require only two applications. This treatment is the best we know for pediculosis capitis in school children and never seems to fail.

Well, these were the children that were evacuated. In one day we succeeded in evacuating 6,370 children from elementary schools to Devon and Cornwall. We undertook to see that all these children were thoroughly inspected and cleansed and equipped with proper clothing before they went. The task of inspecting, cleansing and equipping was undertaken during the week prior to evacuation. The task was no small one. The incidence of uncleanness, scabies, impetigo, and pediculosis was higher than at any time previously, and all of these conditions had to be dealt with during the one week prior to the departure of the children. Moreover, to make the problem harder, these 6,370 children were located not in one but in twenty schools.

All of them received a complete inspection. The first took place four to six days before leaving the city, and the condition of each child was recorded on a special card. Special attention was given to cleanliness, verminous and skin conditions, infectious states, and the difficult child was indicated—the bedwetter and the child with behavior problems—as far as these could be ascertained.

The routine of this preliminary inspection was organized on the "Survey" system. Thirty-four school nurses and health visitors gave assistance to the five available school medical officers, and clerical help was provided by the teachers. Sometimes three or four of the smaller schools had to be covered by the same group of workers in one day, and for this the team was transported from school to school in casualty service vehicles.

Each child was undressed and completely inspected by a nurse. Upon the slightest suspicion of defect the child

was seen by a doctor at a separate table and the condition was more completely assessed. In this way 20 per cent of the children were labelled for treatment. Then the task of remedying the defects had to be accomplished. This was started immediately. Skin conditions, such as scabies and impetigo, and minor ailments were referred to local clinics for treatment. The normal routine of these clinics was temporarily suspended so as to give all affected children a chance of being cleared, and the treatment was active and thorough, so that the large majority were cleared within a week.

Problem children were set aside so that separate arrangements for evacuation, such as into hostels, could be made.

Head lice were the main difficulty. Approximately 15 per cent of the children, ranging from 3 per cent to 20 per cent according to the school locality, were found to be infested with head lice to a greater or lesser degree. It was realized at an early stage that separate arrangements would have to be made for the mass delousing of these children and for this purpose nurses of the Civil Nursing Reserve, "standing by" between night raids, were recruited. These volunteers, fifty in number, underwent a brief period of instruction before starting on the heads. A high standard was set. No child was to be allowed to depart with a single nit. Heroic measures were sometimes necessary in the worst cases but no verminous child left Bristol.

The final inspection took place within 24 hours of departure and was conducted on the same principles. During this inspection particular attention was paid to cleanliness, and to the children found defective at the preliminary examination. As a result of these examinations only one-half of one per cent of the children were considered unfit to travel, and most of these were cases of

scabies that could not be cleared in time. The task was completed within a week.

Altogether 21,000 children were evacuated from Bristol during the succeeding six months; 14,000 under arrangements made by the local authority, and 7,000 to billets secured privately by their parents. Of this number, a total of 8,000 still remain out of the city.

Outstanding among the lessons learned from this inspection were the extent to which shelter life can intensify all the problems of infestation, and the extent of the effects of even a temporary disruption of the social care normally given to school children.

All children who were not properly clothed were provided with all the necessary articles before they were evacuated. During the whole time that they are away continual watch is kept to see that they are adequately and suitably clothed, and if the parents are unable to provide what is necessary, the local authority supplies the need. I make special reference to this because we in Bristol recognize the tremendous debt we owe to the American organizations which have so kindly sent such generous gifts of clothing for our children. I would assure you that these are all well used and most gratefully appreciated.

F. RESIDENTIAL NURSERIES

What has been said about evacuation applies mostly to children over 5 years of age. We still had the problem of the children under 5. For obvious reasons it would be impracticable to expect that they could be billeted out. The only possible way of dealing with them was to take over country mansions and establish residential nurseries. A considerable amount of work was involved in obtaining the necessary accommodation and in rendering it suitable and equipping it for use as a

nursery. Some of these nurseries were administered under the supervision of a head teacher (as a residential nursery school) with a resident nurse adviser. Into these nurseries, the children aged 2-5 years were evacuated. Some were established as residential nurseries under a trained nurse-matron. The children under 2 years of age were evacuated to nurseries under the supervision of trained nurses and a deputy with nursery attendants working under them. The units were mostly of 30/40 children. Arrangements were made for medical supervision by local general practitioners. At present (March, 1943) there are 16 residential nurseries with a total accommodation for 473 children.

G. HOLIDAY SCHEME

The delay in operating the scheme for children under 5 years of age resulted in great strain being placed upon the mothers who had children of this age in the city during the "blitz," and in the spring of 1941 the City Council approved a Holiday Scheme for mothers and children. By this time, Bristol had suffered very badly and the more fortunate adjacent country areas were very sympathetic toward the citizens. Prominent people in these areas helped in the scheme and mothers and children were sent for a fortnight into the homes of families in these adjacent areas. Some towns (like Sidmouth, Devon) undertook to bear the cost involved; otherwise the Lord Mayor's War Services Fund to which American citizens have many times so generously given, helped to defray the expense. In one area a large camp was organized where mothers and children spent part of the summer of 1941, and some of the Oxford colleges were also used as guest houses. To the end of February, 1943, 6,208 people were sent away under this scheme. Every person sent had to have suffered as result of raiding.

H. PRESENT PROBLEMS

I have already mentioned that one of the results of the war is that the young fathers have nearly all disappeared from the city. Those that remain are employed strenuously on war duties and in any case the father is not able to do much in the way of supervision of his children. It is a peacetime problem of great importance to know what to do with the children when the mother falls ill and the home cannot depend upon friends and relations. Friendship comes to the rescue quickly in case of illness, but it cannot be strained too much. We know, for example, that many a mother has left the sanatorium before treatment is completed because her children at home have given too much trouble to friends and relations. Many husbands in peacetime have had to stay away from work because there was no one else to look after the child when the mother was ill. This has been a severe drain upon the family exchequer, often resulting in poverty. In wartime this same problem has been vastly accentuated and there appears to be but one solution—the establishment of residential nurseries by local authorities. The demand for these has therefore increased considerably as the direct result of the war, and every effort is being made in Bristol to provide this accommodation.

I. WARTIME NURSERIES

Another urgent problem today is how to care for children under 14 years of age while the mother is at work and away from home. In order to face this problem, and the growing need for more women on work of national importance, the Government have instructed local authorities to establish wartime nurseries. Here children under 5 years of age may be taken by a mother on her way to work and collected on her return in the evening. For a small pay-

ment the children are cared for and receive all their meals. So far (March, 1943) we have prepared accommodation for about 750 children in these nurseries in Bristol.

J. DAILY GUARDIANS SCHEME

It became clear that the normal rate of provision of wartime nurseries would not meet the problem, for mothers were quickly drafted to industry and munitions. In the late months of 1941, a scheme was devised which would allow for the greatest possible release of women for war work and at the same time take into account the mother who could not leave her home. Under this scheme of Registered Daily Guardians, a woman who cannot leave her own home can register as a "daily guardian." She agrees to take into her own home one or more children under 5 years of age (according to her accommodation) and to care for them each day while their own mothers are at work. Each "guardian" is visited and approved by the local authority, and the Ministry of Labour makes a payment to the guardians. The scheme has gained popularity and runs smoothly in Bristol where at the present time over 200 children under 5 years of age are in the care of "daily guardians." Contact is usually first made between the Ministry of Labour and the local authority, but in many instances the mothers concerned make their own arrangements and then come forward for approval and payment.

K. SCHOOL CANTEENS

The provision of wartime nurseries and the organization of the "Daily Guardians" scheme do not cover the whole of the problem, however—there remains the problem of the child of school age. In an effort to help in its solution, the Bristol Education Committee commenced a scheme whereby every child in an elementary school can

obtain $\frac{1}{2}$ pint of milk each mid-morning, and can obtain a hot midday meal. Meals are not available at every school in the city, but arrangements have been made so that the children from the schools lacking the necessary accommodation can quickly go to a central school for their meal. The teaching profession in the city is supporting this scheme by adding to its responsibilities the supervision of the children in the middle of the day. The Bristol Education Committee is at present bringing into operation a big scheme to increase the supply of meals in school canteens. We hope that the effect of this will be to increase the number of children taking a midday meal at school from 4,000 per day, which is the present figure, to something like 12,000 a day.

L. PLAY CENTERS

The provision of a midday meal for all elementary school children was a step toward the solution of the vast problem of the care of the school child, but it could not cover the after-school hours, when mother and/or father is still at work, nor could it cover the holiday period.

In eighteen centers of Bristol at the present time "youth welfare centers" are established where boys and girls can remain to gain both knowledge and recreation for a couple of hours following afternoon school. Such subjects as arts and crafts and physical training are taken.

This year the Bristol Education Committee has made provision for the opening of playing fields during the summer months, where boys and girls can spend their evening leisure time in healthy exercise and allow their mothers to work undisturbed by worry as to their welfare. The playing fields are available for all children. Should the weather be wet, arrangements are to be made for certain schools to be

opened in the evening hours as "play centers" and "youth welfare centers." To these only the children of war workers will be allowed to come. The centers are staffed by paid officers of the Education Committee.

It has been my purpose in this paper to show how public health authorities in Britain, while concentrating every effort on the immediate task, have succeeded in making provisions for the care of children. In peacetime it hardly seems necessary to draw atten-

tion to the need for protecting the life of a child and the development of its health. In wartime, however, life appears too cheap, so many young adults developed with such care are slaughtered on the field of battle and, in modern warfare, even mothers and children in their own homes. It would be easy therefore to divert all energy and material resources from any long-time policy. Only history can judge the measure of our success in keeping the balance steady.

Laboratory Examination of Eating and Drinking Utensils*

RALPH L. FRANCE, JAMES E. FULLER, PH.D.,
AND W. E. CASSIDY

Massachusetts Agricultural Experiment Station, Amherst, Mass.

IN recent years public health authorities have been giving increasing attention to the proper cleansing and subsequent handling of glassware, dishes, and other utensils that are used in establishments that serve food and drink to the public, and various procedures have been developed here and there for the laboratory examination of such equipment. Attention has centered on the examination of drinking glasses, cups, forks, and spoons, because it is these utensils that come in contact with the mouths of users. Plates and other utensils, however, are sometimes examined; and it is obvious that if contaminated cups and drinking glasses are washed in insufficient water, or in water inadequately heated, and other utensils are washed in the same water, the whole may become contaminated.

The term "sanitization" has been coined to apply to cleansing and handling of eating and drinking equipment. Methods and proposed standards for the examination of the efficiency of sanitization in restaurants, soda fountains, bars, and similar establishments are, to date, only tentative, and the purpose of the present study was to make some contribution to the subject.

LITERATURE REVIEW

A committee of the American Public Health Association¹ proposed a procedure for the bacteriological examination of eating utensils. The principal features of the test were: the multiple spoon test, in which spoons are shaken in sterile salt solution; the multiple glass test, in which glasses are swabbed with damp swabs and the swabs agitated in tubes of sterile salt solution; the multiple plate test, in which measured areas of plates are swabbed with damp swabs that are then agitated in sterile salt solution. All resulting suspensions are plated in the usual way. No mention is made of the time that suspensions may be held before plates are made.

Among the authors who have reported investigations of methods for evaluating the sanitary condition of eating and drinking utensils are Fellers, Levine, and Harvey,² Krog and Dougherty,³ Mallmann,⁴ Speck and Black,⁵ and Ward and Dack.⁶ A compilation of procedures was published by the Public Health Committee of the Cup and Container Institute.⁷ This compilation includes some of the publications mentioned above and also some others, among them being methods used in several municipalities.

Most of the procedures mentioned make use of dry swabs as such, dry swabs moistened in sterile fluid, or

* Contribution No. 475 of the Massachusetts Agricultural Experiment Station.

swabs sterilized in fluid. The general routines call for shaking or for rotating the swabs in a suspending fluid. Then the suspension is plated. In a few instances swabs are also streaked on special media for the detection of special groups of bacteria.

The most commonly used suspending fluids are sterile distilled water or sterile physiological saline. Hucker, et al.,⁸ in a report on food utensil sanitation, employed a "phosphate buffer solution," and the procedure of the New York State Department of Health⁹ specifies that Butterfield's phosphate solution¹⁰ shall be used. Standard nutrient agar is the most frequently used medium. Hucker⁸ used a medium containing tryptone, sucrose, gelatin, yeast extract, and K_2HPO_4 . The procedure in use at Dayton, Ohio, employs dextrose agar, and tryptone glucose extract agar is used in Springfield, Ill. In some instances special media are used in addition to the plating medium. Fellers, Levine, and Harvey streaked swabs on Loeffler's blood serum in an effort to isolate "pathogens," and Ward and Dack used veal infusion agar for *Eberthella typhosa* and *Staphylococcus aureus*, and injected guinea pigs to test for *Mycobacterium tuberculosis*. The presumptive test for the coliform group of bacteria has been used in some technics.

In addition to the swabbing technic, Hucker,¹¹ and Walter and Hucker,^{12, 13} have reported the use of a "contact plate" method in the place of swabbing methods for rapid tests.

Few of the procedures give any directions as to the length of time that may be permitted to elapse between swabbing and plating. Fellers, Levine, and Harvey state that swabs should be returned to the laboratory within 2 hours after the swabbing; the procedure employed at Washington, D. C.,⁷ permits 3 hours to elapse; the Michigan Agricultural Experiment Station

procedure states that swabs should be returned to the laboratory "immediately." The Standard Methods tentative procedure does not mention the time factor.

The list of procedures referred to here is not intended to be complete, but rather to give a cross-section view of those in common use. All are more or less tentative and changes may be expected as new information on the subject becomes available.

TYPES OF SWABS

The experiments of the first series were concerned with the relative efficiency of damp and wet swabs for removing bacteria from contaminated drinking glasses. Dry swabs are specified in some procedures, and they could be of use in swabbing moist surfaces. However, in practical inspection, most if not all of the utensils swabbed would be dry, and a dry swab obviously would be ineffective. At the beginning of this investigation dry swabs were used, together with the moist and wet swabs. It soon became evident that the dry swabs were inefficient for removing bacteria from dry utensils, so their use was discontinued and no results appear in the tables.

Swabs were made by twisting absorbent cotton onto wood applicator sticks. Two kinds of swabs were used in the experiments; *damp swabs* that had been moistened, but not saturated, with distilled water before they were sterilized, and *wet swabs* which were sterile dry swabs dipped into sterile distilled water or other suspending fluid just before they were used. Excess fluid was removed from the wet swabs by pressing them against the wall of the container before they were removed from it. All swabs and suspending fluids were sterilized in an autoclave at 15 pounds steam pressure for 15 minutes. For the wet swabs it was necessary to sterilize swabs and fluid sepa-

rately and to dip the swabs just before they were used, because when the swabs were sterilized in the fluid the sticks became so limber that it was impossible to exert the pressure necessary to remove the excess fluid from the swab or to remove bacteria satisfactorily from the surface of a glass. The use of wire instead of sticks would remove this difficulty, but sticks were preferred because it was found that the best way to remove the bacteria from the swabs was to break the sticks just above the cotton with sterile forceps and drop the swabs into containers of sterile suspending fluid.

In swabbing drinking glasses the swabs were held in the fingers as near to the cotton as possible without contaminating the swab. After swabbing was completed the sticks were broken and the swabs were dropped into bottles containing 100 ml. quantities of suspending fluid. The bottles were shaken until the cotton fluffed out, and then suitable dilutions were made and plated. Plates were incubated for 48 hours at 37° C. and then counted. The procedure for making and using the swabs remained constant through the study here reported, and standard procedure was employed in making plates. The suspending fluid used was varied as indicated later. Nutrient agar was used for plating until another medium was substituted as indicated in the text.

In the first experiment straight-sided

flat-bottomed drinking glasses of about ½ pint capacity were employed. These are referred to as glasses. They were sterilized and cooled, and then were dipped into a bacterial suspension to a depth of about ½ inch and rotated to insure complete wetting of the rims. They were then placed in a sterile rack and allowed to dry, and were protected from air contamination while they were drying. The organism employed was a strain of micrococcus isolated from a glass that had been used for drinking. The bacterial suspension was prepared by inoculating sterile nutrient broth and incubating for 24 hours at 37° C.

In this experiment sterile distilled water was used for dampening or wetting the swabs and for the suspending fluid. Glasses were dipped separately into four different suspensions of the micrococcus. These suspensions are designated in Table 1 as trials 1 to 4, inclusive. The glasses were allowed to dry, and some in each group were swabbed with two successive damp swabs and an equal number with two successive wet swabs. The second swab was used in each case to recover bacteria which had been missed by the first swab. Counts from the first swabbings were calculated as percentages of the respective total counts of both the first and second swabbings.

The total counts from the different glasses varied even with the same type of swab, probably because it would hardly be expected that contamination

TABLE 1
Comparison of Counts from Damp and Wet Swabs Used for Swabbing Drinking Glasses—First Counts Calculated as Percentages of Totals

Trial	Counts from Damp Swabs				Counts from Wet Swabs			
	1st	2nd	Total	Per cent	1st	2nd	Total	Per cent
1	8,400	600	9,000	93	7,800	600	8,400	93
2	2,000	200	2,200	91	14,700	200	14,900	99
3	11,000	980	12,180	92	34,500	1,100	35,600	97
4	9,100	800	9,900	92	2,750	320	3,070	90
Average Percentage				92				95

Note: Counts represent number of bacteria per ml. of suspension.

would be uniform. The percentage of the total for each glass recovered by the first swabbing was nearly the same for the two types of swabs. This suggested that the two types were about equally effective.

The possibility existed, however, that the damp swab did not remove as many bacteria as did the wet swab on either the first or second swabbing. If that were true, the apparent equality of the two methods in the first experiment would be misleading. In order to compare the results when damp swabs were followed by damp swabs on one series of glasses, and by wet swabs on another series, 24 sterile glasses were dipped into a suspension of the same micrococcus used before and dried. Twelve of the glasses were swabbed with three successive damp swabs each, and each of the other 12 with a damp swab and then with two successive wet swabs. Results are shown in Table 2.

counts for the first swabs averaged 94 per cent of the totals, and when a damp swab was followed by two successive wet swabs the average for the first swabs was only 80 per cent of the totals. These data indicate that, when only one swab is used per glass, as would be the case in practical inspections, the wet swabs would be substantially more efficient than the damp swabs in removing bacteria from contaminated surfaces.

PERCENTAGE OF ORGANISMS RECOVERED WITH WET SWABS

Another trial was made to determine as nearly as possible the percentage of organisms that could be recovered from glasses with wet swabs. A bacterial suspension was prepared as before and equal measured quantities were spread on the rims of glasses by means of a sterile capillary pipette. The glasses were allowed to dry and then swabbed

TABLE 2

Relative Efficiency of Damp and Wet Swabs as Indicated by Counts from Glasses

Three Successive Damp Swabs—Count for First Swabs Calculated as Percentages of the Totals						One Damp Swab Followed by Two Wet Swabs—Counts from First Swabs Calculated as Percentages of Totals

12	69,000	1,050	120	70,170	98	24	22,000	3,600	280	25,880	85
Average Percentage					94	Average Percentage					80

Note: Counts represent number of bacteria per ml. of suspension.

Again the total counts from the different glasses varied and comparison means little. The significant factor is a comparison of the counts from the first swabbings with the respective totals. Table 2 shows that when three successive damp swabs were used the

with one wet swab each, and the resulting suspensions were plated as in the preceding experiment. At the same time several portions of the suspension, each equal to the amount spread onto the glasses, were plated. The average of these counts was taken as 100 per

cent and the counts from the glasses were calculated as percentages of this average. Results are shown in Table 3.

TABLE 3

Counts from Glasses Inoculated with Bacterial Suspension and Swabbed with Wet Swabs—Counts from Swabs Calculated as Percentages of Count from Suspension—33,900

Glass No.	Count	Per cent
1	27,700	82
2	35,700	105
3	29,800	88
4	34,800	102
5	26,400	78
6	32,900	97
7	29,200	86
8	22,000	65
9	27,900	82
10	24,500	72
11	25,500	75
12	26,100	77
Average Percentage		84

Note: Counts represent number of bacteria per per ml. of suspension.

The counts from the different swabs varied. While it is improbable that the inoculations on the glasses contained uniform numbers of bacteria, the procedure should be indicative of the efficiency of the swabs in recovering bacteria from glasses and utensils sufficiently to indicate whether or not the sanitization of these articles had been satisfactory. Some of the counts from glasses were approximately equal to the average from the suspension, the lowest recovery was 65 per cent, and the average was 84 per cent. This result indicates that if a representative number of glasses or other utensils are swabbed in any eating place, the result should make possible a practical evaluation of the sanitizing practices of the establishment.

FLUIDS USED TO WET SWABS

In the experiments reported up to this point, sterile distilled water was used to moisten or wet the swabs. Another experiment was done to determine the effect of using other fluids to wet the swabs. Three fluids were used:

sterile distilled water, sterile tap water, and sterile physiological saline. Three series of swabs were wet with these respective fluids. Glasses were dipped into a bacterial suspension and allowed to dry. Then they were swabbed and the resulting suspensions were plated as in the preceding experiments. Two successive swabs were used on each glass and the count from the first swab in each instance was calculated as a percentage of the total of the two counts. The average of the percentages of bacteria recovered by the first swab for each fluid was as follows:

Wetting Fluid	Average Percentage recovery on First Swab
Distilled water	95.5
Tap water	95.8
Physiological saline	95.6

These results indicate that no one of these agents has any advantage over the others for the wetting of swabs.

SUSPENDING FLUIDS

It is obvious that plates should be made as soon as possible after glasses or other utensils have been swabbed, and some of the procedures in use or recommended specify that not more than 2 hours, or 3 hours at most, shall elapse between swabbing and plating. In the practical inspection of establishments serving food and drinks to the public it may happen that a considerably longer time will elapse, particularly if an inspector does his own laboratory work, as is often the case in smaller communities. He might spend a morning making inspections and taking samples, and do the plating in the afternoon. For this reason the effect of holding periods longer than 2 hours on the survival of bacteria in suspending fluids was investigated in the effort to find a satisfactory fluid for the purpose.

The fluids selected for the first experiment were three that are commonly employed for this and other purposes:

distilled water, physiological saline, and Butterfield's phosphate solution.¹⁰ Butterfield's solution is employed because it is buffered to prevent the solution becoming excessively acid, and this fact suggested additional fluids for use here: distilled water with added di-potassium phosphate, Butterfield's Formula C,¹⁰ and Butterfield's phosphate solution with added sodium hydroxide to make the solution definitely alkaline.

Several persons were asked to dry-drink several glasses each: that is, the glasses were empty, but the subject wet his lips with his tongue and put a glass to his lips as if he were drinking from it. Several glasses were used by each person for each of the suspending fluids studied. The glasses were then allowed to dry and were swabbed with wet swabs. Plates were made immediately after the swabs had been dropped into the fluid, and again after the suspensions had stood at room temperature (about 22° C.) for 5 hours. All technic was the same as that used earlier except that a yeast-extract neopeptone agar containing dextrose was employed instead of nutrient agar. (Some work done after this investigation was under way indicated that the yeast-extract neopeptone agar gave better results than did the nutrient agar. In order that the continuity of the narrative may not be interrupted, the experiments with the medium are placed at the end of this report.) The results obtained with the several suspending fluids are shown in Table 4.

The highest percentage of survival (8.9 per cent) after 5 hours was in Butterfield's phosphate solution and the lowest (1.3 per cent) was in distilled water. The survival (2.3 per cent) in physiological saline was not much better than that in distilled water. The percentages of survival (8.0 per cent and 8.6 per cent respectively) in distilled water with added di-potassium phosphate and Butterfield's phosphate solution with added sodium hydroxide were nearly as good as that in Butterfield's phosphate, but his Formula C showed survival (2.6 per cent) nearly as low as that with physiological saline. None of the fluids, however, sustained the viability of the suspended bacteria satisfactorily for the 5 hour standing period.

The purpose of the next experiment was to determine how rapidly the numbers of bacteria decreased when swabs were held in suspending fluids. The experiment was set up in the same way as that just preceding, except that only physiological saline and Butterfield's phosphate solution were used—the former because it is a common diluting and suspending fluid, and the latter because it had given the best results of the fluids tried in the previous experiment. Twelve glasses were dry-drunk, dried, swabbed, and the swabs suspended in physiological saline; and 12 additional glasses were similarly treated and the swabs suspended in Butterfield's phosphate solution. Plates were made immediately after the swabs were

Note: Counts represent number of bacteria per ml. of suspension.

put into the respective fluids; then the suspensions were held at room temperature and plates were made at $\frac{1}{2}$ hour intervals up to 3 hours. Results are shown in Tables 5A and 5B. There was a steady decrease in the counts throughout the holding period in both fluids, and even at 30 minutes the decrease was sufficient to make the results of little value in the practical testing of utensils. These findings indicate that holding periods of 2 to 3 hours, permitted in many of the proposed technics, would not give an adequate estimate of the sanitizing procedures in use at eating and drinking establishments.

EFFECT OF CHILLING ON THE VIABILITY OF BACTERIA IN SUSPENSION

In attempting to reduce the loss of bacteria held in suspension, it was decided to try the effect of chilling. Used glasses (dry-drunk) were swabbed as before and swabs from one series of glasses were put into chilled physiological saline and from another series into chilled Butterfield's phosphate solution. The suspending fluids had been chilled by immersing them in a bath of iced water, and the temperature of the bath was maintained at 3° to 5° C. Plates were made immediately after the swabs were dropped into the fluids, and at 1, 2, and 5 hours. Results are shown in Table 6.

The loss of bacteria was much less than in the same fluids held at room temperature (see Tables 5A and 5B). A summary of the comparison shows the following percentages of organisms surviving:

	Per cent Surviving		
	1 Hour	2 Hours	5 Hours
Butterfield's phosphate, room temperature	44.9	22.2	10.3
Butterfield's phosphate, chilled	93.0	86.0	73.0
Physiological saline, room temperature	43.3	20.8	9.5
Physiological saline, chilled	83.6	66.1	34.5

With the chilled suspensions Butterfield's phosphate solution gave definitely better survival percentages than did physiological saline. With the chilled phosphate solution the survival of organisms was such that suspensions held up to 1 hour should yield counts entirely satisfactory for evaluating the sanitary condition of eating and drinking utensils examined, and survival up to 2 hours would appear to be adequate for a usable interpretation of the counts to be made. This is important because holding periods of from 1 to 2 hours are almost unavoidable in practical field work. Even if suspensions should be held for as long as 5 hours it would still be possible to detect poor sanitization of utensils even though the borderline cases would get by. Results with chilled physiological saline would not be useful after 1 hour of holding.

The results obtained with chilled Butterfield's phosphate solution indicate that it can be recommended as a suspending fluid for the sanitary examination of eating and drinking utensils.

PRACTICAL APPLICATION

Up to this point all of the experimental work had been done in the laboratory, so it was decided to try the method under practical conditions. Several establishments serving food were visited as a sanitary inspector would visit them. Included were several boarding houses, a restaurant, and a bar. Drinking glasses supposed to be clean were swabbed with wet swabs, and physiological saline and Butterfield's phosphate solution were employed for suspending fluids. Bottles of these fluids were placed in iced water containers before they were taken from the laboratory and were kept chilled until the final plates were made. Swabs were dropped into the suspending fluid immediately after the swabbing was done; and as soon as possible,

Average Percentage			75				92

Note: Counts represent number of bacteria per ml. of suspension. Chilled suspending fluids were used.

always within 1 hour, the suspensions were returned to the laboratory where plates were made immediately and again after 2 hours.

Representative results are shown in Table 7. Counts at 2 hours are calculated as percentages of the counts made from the first platings. Again, results from Butterfield's phosphate solution were better than those from physiological saline. The average survival after 2 hours was 92 per cent for the phosphate solution, and only 1 of the 12 samples showed less than 85 per cent. With the physiological saline only 3 of 12 samples showed over 80 per cent survival, and 88 per cent was the maximum. The average was 75 per cent.

On the basis of these results, chilled Butterfield's phosphate solution was definitely superior to chilled physiological saline as a suspending and holding fluid, and the results again indicate that the chilled phosphate solution can be recommended as satisfactory for the practical testing of the effectiveness of the sanitization of eating and drinking utensils.

MEDIA

In the first few experiments of this investigation nutrient agar was em-

ployed for plating. This medium, however, probably does not adequately promote the growth of some significant types of oral bacteria, particularly streptococci. It is a matter of common knowledge that streptococci, and particularly non-pyogenic types such as *Streptococcus salivarius*, are common mouth flora. Dick and Hucker¹⁴ proposed that the detection of oral streptococci be employed as a presumptive test for evaluating the sanitization of eating and drinking utensils. It appeared to be desirable, in the present study, to devise a medium that would be likely to produce good growth of streptococci and any other oral organisms that do not grow well on ordinary media.

In considering materials to be used in the new medium, it was decided to incorporate dextrose, neopeptone, and yeast extract. Dextrose is a growth stimulant for most bacteria. Neopeptone is suitable for the growth of bacteria that are fastidious in their feeding habits; it is recommended especially for cultivating pneumococci and streptococci. Lancefield¹⁵ used neopeptone in her work on the classification of streptococci. Bacto-yeast extract has been used¹⁶ to promote

growth of bacteria that are difficult to cultivate, and Hutner¹⁷ used it in his basic medium in making nutrition studies with streptococci. The composition of the medium used here was as follows:

Neopeptone, Difco	10.0 gm.
Bacto-yeast extract, Difco	5.0 "
Dextrose	0.5 "
Sodium chloride	5.0 "
Bacto-agar, Difco	15.0 "
Distilled water	1,000.0 ml.

The reaction was adjusted to pH 7.5 and the medium was sterilized at 15 pounds steam pressure for 15 minutes. This medium, referred to earlier as yeast-extract neopeptone agar, is somewhat similar to that used by Hucker.⁸

A number of stock laboratory cultures of streptococci, both hemolytic and non-hemolytic, were streaked on plates of both media. Colonies were larger and growth in general was better on the yeast-extract neopeptone agar than on nutrient agar. Then a series of glasses were "dry-drunk" by several persons and swabbed. Suspensions from the swabs were plated on both media. Representative results are shown in Table 8. Definitely larger counts were obtained on the yeast-extract neopeptone medium, and colonies were larger in general than on the

nutrient agar. Recommendation of the yeast-extract neopeptone medium seems to be justified for use in evaluating the sanitization of eating and drinking utensils.

SUMMARY

Two kinds of swabs were used, designated as damp and wet swabs. The former were moistened in fluid and then sterilized in a test tube without additional fluid. The wet swabs were first sterilized dry in a test tube, then just before they were used they were wet thoroughly in sterile fluid and the excess fluid squeezed out against the side of the tube. The wet swabs proved to be definitely more efficient than the damp swabs in recovering bacteria from the rims of drinking glasses. Distilled water and physiological saline were equally satisfactory for wetting the swabs.

Several suspending fluids examined were: distilled water, physiological saline, Butterfield's phosphate solution, Butterfield's Formula C, distilled water with added K₂HPO₄, and Butterfield's phosphate solution with the pH value raised by addition of NaOH. The survival of bacteria in these fluids up to 5 hours at room temperature was investigated. Distilled water was least satisfactory, and Butterfield's phosphate solution gave the highest percentage of survival. None was sufficiently satisfactory for practical use. Saline and Butterfield's phosphate solution were again investigated and counts of suspensions were made at 30 minute intervals. Neither fluid sustained bacterial viability satisfactorily for even 30 minutes.

Bacterial suspensions were made in Butterfield's phosphate solution and in physiological saline, both of which were chilled by immersing the containers in an iced water bath. Butterfield's phosphate gave excellent survival at 1 hour

TABLE 8

Comparison of Counts from Swab Suspensions on Two Media—Counts on Nutrient Agar Are Calculated as Percentages of Counts on Neopeptone-Yeast-Extract Agar

5	4,200	3,600	86
6	6,200	4,400	71
7	360	270	75
8	720	460	64
9	390	210	54
10	7,100	3,000	42

Note: Counts represent number of bacteria per ml. of suspension.

and satisfactory survival at 2 hours. Even at 5 hours the survival was sufficient to permit detection of definitely poor sanitization procedures. Practical field tests verified the experimental results.

A medium containing neopeptone, yeast extract, and dextrose gave much better growth of oral streptococci than did nutrient agar. It also gave higher counts and larger colonies than were obtained on nutrient agar.

As a result of this investigation the following recommendations are made:

1. Swabs should be made on wood applicator sticks and sterilized dry. Just before a swab is used it should be wet thoroughly in a sterile fluid and excess fluid squeezed from the cotton by pressing the swab against the inside wall of the container. The kind of fluid used to wet the swab makes little difference, but it would be well to use the same fluid that is used for suspensions.

2. Wet swabs should be rubbed thoroughly over the surfaces to be examined; then the sticks should be broken just above the cotton with flamed forceps and the swabs dropped into containers of sterile suspending fluid. The containers, preferably bottles, should be shaken until the cotton of the swabs fluffs out. Plates may be made in the usual way.

3. Butterfield's phosphate solution is recommended for use as a suspending fluid. Sterile containers—tubes or bottles—of the solution should be immersed in ice water and chilled before they are used, and kept chilled until plates are made. It is desirable that plates be made within 1 hour after swabbings have been done, but usable results can be obtained if it is necessary to hold the suspensions up to 2 hours. A longer holding period should be avoided if it is at all possible.

4. A medium should be employed that will support the growth of certain fastidious bacteria, and especially oral streptococci. Such

a medium, consisting of 10 gm. neopeptone (Difco), 5 gm. Bacto-yeast extract (Difco), 0.5 gm. dextrose, 5 gm. sodium chloride, 15 gm. Bacto-agar (Difco), and 1,000 ml. water, pH 7.5, gave good results.

Venereal Disease Epidemiology

Third Service Command

An Analysis of 4,641 Contact Reports

SENIOR SURGEON E. W. NORRIS, MAJOR A. F. DOYLE, M.C.,
AND ALBERT P. ISKRANT

*Liaison Officer, U. S. Public Health Service; Venereal Disease Control Officer;
and Statistician, U. S. Public Health Service*

IN the summer of 1940, the Army, Navy, Federal Security Agency, and state health departments entered into the well known Eight Point Agreement on measures to be developed for the control of the venereal diseases. Out of this joint agreement there has developed a great network of activities which should produce the lowest venereal disease rate in the history of the Armed Forces and should entangle in its meshes enough of the syphilis and gonorrhea in this country to curb the further spread of this blight on our national health.

The Army and Navy have undertaken to furnish to the civil health authorities information which will lead to the discovery of disease in the civilian communities. At the beginning of the program the forms used by the

various Army stations for reporting contacts of venereal disease to the health authorities varied considerably in detail but the nature of the information which they conveyed was basically the same, that is, the name and address of the alleged contact, when obtainable, and her description. There has evolved from that heterogeneous collection the standard Army form, MD-140 "Report of a Contact of Venereal Disease," shown in Figure 1. The reverse side of the form is designed for reporting the result of the investigation.

The system instituted in the Third Service Command provides for the reports of the results of health departments' investigations to be routed back to the camp of origin through the Service Command Headquarters. Here, with the assistance of the Public Health

16-502-1

Service Central Tabulating Unit, a statistical record is kept and an analysis of 4,641 contact reports covering the period March 1 to December 31, 1942, has been made in an effort to ascertain the relative importance of the component parts of the problem and to measure the effectiveness of the Army-Health Department Control Program.

Figure 2 shows that the reported con-

tacts were distributed widely throughout the United States, although the Third Service Command comprises only the States of Pennsylvania, Maryland, and Virginia.

Table 1 represents an evaluation of the information furnished to the health departments. According to completeness, the information fell into one of three categories: (1) sufficient for the

★ U. S. GOVERNMENT PRINTING OFFICE 1942 16-51715-1

location of the alleged contact; (2) sufficient to provide a possible lead for the location of the alleged contact or to point out places which appear to facilitate the transmission of disease; and (3) insufficient for any practical purpose. Each contact report was appraised on its face value by one of the authors. It is recognized, however, that this evaluation is not absolute because of the element of uncertainty or deliberate misrepresentation on the part of the informant. Nevertheless, the results of the investigations bear out the relative validity of the appraisal.

Table 2 shows the classification of the alleged contact. It indicates that the "prostitute class" (fee paid), namely

the streetwalker, brothel inmate, and call-girl accounted for only 21.1 per cent of the infections, while "friend" or "casual pickup" (no fee) accounted for 72.1 per cent of the infections. The wife was named as the probable source or as an exposed contact in 6.6 per cent of the cases. Evidence from other sources seems to substantiate these figures. It was found that among the sources of infection of soldiers in the British Army 80 per cent were the "casual" or "amateur" type.¹ It has been stated that 85 per cent of the contacts of Australian soldiers are non-professional.² Venereal disease contact reports from nine continental naval stations during an 8 month period in 1942

indicate that 77 per cent of the infections were due to "girl friends" or "casual pickups."³ In figures released by the United States Air Force, brothels were reported as being responsible for 5 per cent of the infections with

"casual pickups" and "friends" accounting for 80 per cent.⁴

Table 3 shows the place of procurement or encounter. The tavern class, which includes restaurant, cafe, and night-club, leads with 35.6 per cent;

* The results of investigation are presented only on 3,173 contacts reported through October, 1942, as a minimum of 2 months is allowed the health department to investigate the case.

street encounters were next with 30.7 per cent; and the remaining 33.7 per cent widely distributed as shown.

Table 4 shows the place of exposure and indicates that the home, apartment, hotel, or rooming house was named in 53.1 per cent of the cases. The automobile was next most frequently named with 20.9 per cent. Taxicabs and tourist cabins were mentioned less frequently than had been expected, namely 1.3 per cent for the former and 2.8 per cent for the latter.

Table 5 shows the results of the investigations by the health departments. Only those cases which were reported for investigation during the period March 1 to October 31, 1942, are included in this table, since the health departments were allowed at least 60 days in which to report the disposition before the cases were closed for this compilation. Of the 3,173 contacts reported during that period, reports of dispositions by the health departments were returned in 1,989 cases or 62.7 per cent. Located contacts amounted to 684, or 21.6 per cent, of which 326, or 10.3 per cent, of the total were found infected. It was found that 28 per cent of these were already under treatment by the time the investigation was made. Therefore, out of 3,173 reported contacts, only 234 previously unknown cases of disease were immediately uncovered. Eight hundred and sixty-six, or 27.3 per cent, could not be located upon investigation and no attempt was made to locate 439 contacts because of the lack of useful information.

COMMENTS

The Army has undertaken the task of securing contact information from all venereal disease patients in order that epidemiologic investigations may be made by the Civil Health Authorities. The Army is obliged, therefore, to determine whether or not the time and effort spent in initiating the process is

justified by the results obtained. Are the health departments "following up" the contacts and are the infected contacts appropriately treated so that they will not infect more soldiers? Is the program contributing enough to the war effort to justify its continuance? These questions can be answered authentically only through such periodic analyses as the one here presented.

It appears from this analysis that at the present time 80 per cent of the problem depends upon the control of clandestine sources of disease. It is also apparent that the epidemiologic methods demonstrated in this study have definite limitations. It is our opinion, however, that the epidemiologic program, as it is now set up, could function with much greater effectiveness if the Army stations would exercise more care and diligence in obtaining contact information, and if the health departments would make full use of the information furnished. Although no attempt has been made in this paper to show the comparative effectiveness of the venereal disease control work in the several Army camps or by the various health departments, the authors have had the opportunity to make such comparisons from the basic data.

The Army personnel who interview the patients should be trained for this work. Those stations which have consistently furnished superior information have Venereal Disease Control Officers who appreciate the value of careful questioning. Some stations have made profitable use of trained health department interviewers. It has been shown to be important to interview the new patient before he has had an opportunity to be coached by his ward mates. The station which has consistently furnished the best contact information has a trained enlisted man who interviews the patient immediately upon admission, before he is taken to the ward.

Curiously enough, this same station has had the lowest average venereal disease rate of all stations in the Third Service Command.

A study of the reports from health departments indicated that the "follow-up" activities of some lack vigor and purposefulness. In many instances the investigations were delayed several weeks after the contact information had been received by the health department. The notation was often made that the alleged contact "refused to be examined," or, "has not reported to the clinic as directed." Many "could not be located," although the place of residence or place of employment was known. There was considerable evidence that some health officers failed to exercise the authority vested in them for the control of communicable diseases. On the other hand, it is expected that among the 1,184 unreported cases there are many upon which the health departments will report later. It also seems reasonable to assume that among the 684 contacts who were located by the health departments there were individuals who were responsible for more than one soldier's infection, but who may not have been recognized as the same person described on different contact reports. When the contact could be definitely identified, however, on more than one report and was located by the health department, it is possible that she may have been included in one of the "located" columns more than once. These possibilities should be borne in mind when critically evaluating the effectiveness of the program.

The fact that a diagnosis of disease was made in only about 50 per cent of the located contacts may be partially explained on the basis of the acknowledged deficiency of the laboratory diagnosis of gonorrhea, particularly in the female; also on the basis that many suspects may have recovered from their

infection by the time the health department examination was made.

If health departments could develop as thorough case finding programs in their own clinics as the Army has done, and if private physicians would comply with the rules and regulations governing the reporting of venereal diseases, which are in effect in most states, and would take an active interest in venereal disease epidemiology, progress in bringing these diseases under control would be greatly accelerated.

It is evident also from this analysis that the interstate spread of the venereal diseases constitutes a serious problem. In spite of this fact the Interstate Quarantine Regulations governing the travel of venereally infected persons are seldom applied. The time may be opportune for revising these regulations by expanding their scope to cover not only the interstate traveler but also the individual who has exposed the traveler to disease. It would be impractical to attempt to enforce the existing regulations in the case of members of the Armed Forces.

Commercialized prostitution seems to be reasonably well repressed. The scattered remnants of the racket are permitted to survive only because of the tolerant, frequently patronizing, attitude on the part of public officials in certain communities. Any community can reduce commercialized prostitution to an insignificant minimum if it has a mind to do so.

SUMMARY

1. During a 10 month period, 4,641 venereal disease contacts (1,897 white, 2,639 colored, and 105 other) were reported to health departments. The dispositions of 62.7 per cent of the cases were reported back by the health departments.

2. Although reported by soldiers in the Third Service Command, the exposures took place with girls in all but 9 of the 48 states.

3. Thirty per cent of the contact forms contained information considered adequate for location of the contact; an additional 27

per cent contained sufficient information for possible location of the contact or of places in which venereal disease has been acquired; and 43 per cent contained insufficient information for any practical purpose. The colored soldiers gave slightly better information than the whites.

4. The pickup to whom no fee was paid was the leading source of infection (64 per cent white and 45 per cent colored). The streetwalker (fee) was responsible for about 14 per cent of the infections, and brothels 6 per cent. The paid prostitute constituted only one-fifth of the sexual contacts.

5. The tavern (cafe, restaurant, night-club) was the leading place of encounter for both clandestine contacts and prostitutes with "street" next in order.

6. The automobile was the most common place of exposure for white clandestine contacts and the home or apartment for colored. Hotels and rooming houses accounted for the next highest proportion for both white and colored.

7. The brothel was the most common place of exposure for both white and colored prostitutes but proportionately higher for

white than colored. The hotel or rooming house ranked second for white prostitutes whereas the home or apartment ranked second among colored prostitutes.

8. Of the 3,173 contacts reported to health authorities by camps and stations in the Third Service Command, March through October, 1942, approximately 22 per cent were located by the close of the compilation period, December 31, 1942. Approximately 50 per cent of those located showed no conclusive evidence of infection at the time of examination. Of those found infected, 28 per cent were under treatment prior to the investigation.

The Course of the Serologic Tests during Therapeutic Malaria in Patients with Syphilis*

BERNARD I. KAPLAN, M.D., AND I. JAY BRIGHTMAN, M.D., MED.SC.D.

Physician, Sing Sing Prison Hospital, Ossining, N. Y., and Acting Director of Syphilis Control, Westchester County Department of Health; and Consultant, Division of Syphilis Control, New York State Department of Health, Albany, N. Y.

IN connection with investigations on the rôle of malaria in the treatment of syphilis, changes were noted in the quantitative serologic tests during the course of the induced infections. These findings form the basis for this report.

We know of no previous systematic study of the effect of malarial infection upon the quantitative determination of reagin in the serum of patients with syphilis. On the other hand, the development of a false positive serologic test for syphilis during the course of malaria in non-luetics seems to be well established by the recent investigations of Kitchen, Webb, and Kupper,¹ and of Burney, Mays, and Iskrant.² The earlier literature on this subject has been reviewed by Hazen and his collaborators.³

METHODS AND MATERIAL

All individuals included in this report were studied at Sing Sing Prison Hospital with the exception of 10 patients who were observed in collabora-

tion with Dr. Evan W. Thomas at Bellevue Hospital. Patients with latent or central nervous system syphilis who were to receive malaria therapy were hospitalized on the day of inoculation and were permitted to have 6 to 8 febrile paroxysms. The infection was terminated with either quinine sulfate or atabrine. Intensive arsenotherapy with mapharsen was given either by intravenous drip⁴ before or after the anti-malarial agents or by the multiple syringe method⁵ which was given concurrently. With the former method the patient received the infusions on 3 consecutive days totalling 600 to 720 mg. of mapharsen while with the latter technic 10 daily injections of 60 mg. of mapharsen were given.

Thirty-three patients with latent or central nervous system syphilis were inoculated with *Plasmodium malariae* and 11 patients were inoculated with *Plasmodium vivax*. The strains employed have been in constant use for several years and have been observed to produce characteristic clinical infections in susceptible individuals.

To control our observations upon the changes in serologic tests in syphilitic individuals during the course of thera-

* From the Syphilis Control Office, New York State Department of Correction and the Department of Medicine, New York University College of Medicine.

Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

peutic malaria, we are reporting serologic studies made on 50 patients with latent and central nervous system syphilis who were treated with fever induced by intravenous typhoid vaccine combined with intensive mapharsen drip therapy. In addition, we are recording our observations on a group of 25 patients with latent syphilis who received intensive mapharsen drip therapy alone. These 2 groups have been previously described.⁴

An analysis of the patients in these various therapeutic groups showed no significant differences regarding age or color, duration of the disease, previous therapy, and initial serologic titer. In general, the previous treatment was irregular and usually inadequate. The duration of the disease, when known, was evenly distributed between 3 and 20 years in all groups. The age groups would be too small to warrant a breakdown in that regard.

Serologic studies were done 3 times weekly during the course of induced malaria and daily during typhoid vaccine fever and arsenotherapy. All serologic studies were performed in the Division of Laboratories and Research, New York State Department of Health, Albany, N. Y. The complement-fixation test, which was done on all specimens, was the quantitative procedure described by Wadsworth, Maltaner, and Maltaner.⁶ In addition, quantitative flocculation titers were determined simultaneously on many of the specimens obtained from the malaria treated patients, using both New York State⁷ and Kahn⁸ procedures. As the results obtained with these two flocculation tests were essentially identical, only the Kahn titers will be reported as this latter test has had more universal usage.

To control the effects of malarial infection upon serologic reactions other than those associated with syphilis, 6 patients were vaccinated with *Eber-*

thella typhosa antigen a few weeks prior to inoculation with *P. malariae*. Quantitative *E. typhosa* agglutination titers were then determined throughout the course of the malarial infection. The course of the antibodies was controlled by following the titers of 7 vaccinated patients who did not receive malaria therapy.

As this report is concerned only with the serologic changes referable to the actual malarial infection and not to the serologic response noted months later, the results presented include only those occurring during the febrile period and the subsequent week.

RESULTS

Tables 1, 2, and 3 refer to patients receiving therapeutic malaria and record the day following inoculation upon which the first febrile paroxysm occurred, the initial quantitative complement-fixation and Kahn flocculation titers just prior to inoculation, the first day upon which there was noted a tendency of the titer to rise or fall, and the maximal extent of that change. In the case of the complement-fixation test the maximal change is also recorded in terms of the percentage of the initial titer. The Kahn titers are expressed in units.⁸ In all but two instances the trends were first noted during the course of the malarial infection but the progression frequently extended into the week following the last paroxysm. The highest or lowest levels reported, therefore may have occurred while the patient was receiving atabrine, quinine sulfate, or intensive arsenotherapy. The negative effect of the latter type of therapy upon the serologic titer is indicated by the control studies.

Of the 23 patients with central nervous system syphilis who were treated with *P. malariae* infection (Table 1), 22 exhibited a progressive fall in complement-fixation titer during the course of the febrile paroxysms. With the one

* Noted in days after inoculation with *Plasmodium malariae*

exception noted, the titer in each instance dropped to a level less than 60 per cent of the initial titer and in 7 instances the fall was to 20 per cent or less. Flocculation tests were done on 6 of the 23 patients. Only 1 showed a fall in Kahn units paralleling the drop in complement-fixation titer. The other 5, including the patient who showed no fall in complement-fixation

titer, showed a significant rise in the level of Kahn units, although a subsequent fall was noted before the termination of the infection. Of the 10 patients with latent syphilis who were inoculated with *P. malariae* (Table 2), 8 showed a fall in complement-fixation titer to less than 60 per cent of the initial level. In 2 instances this fall was first noted just after, rather than prior

* Noted in days after inoculation with *Plasmodium malariae*

to, the last paroxysm. Kahn tests were done on all of these individuals. Nine exhibited a significant rise in titer, followed in 7 instances by a subsequent fall. The 2 patients in whom a subsequent fall in Kahn units failed to occur were the same individuals who had exhibited no fall in complement-fixation titer.

Thus, of 33 syphilitic patients treated with quartan malaria, 30 exhibited a progressive fall in the complement-fixation titer for syphilis during the induced malarial infection. Of 16 of the 33 on whom quantitative Kahn tests were performed, 14 exhibited an increase in Kahn units, 1 a decrease, and 1 showed no change at all. In 12 of the 14 who showed an increase in Kahn units a subsequent fall occurred before or just after the last malarial paroxysm.

Among the 11 patients with central nervous system syphilis who were treated with *P. vivax* infection (Table 3), 6 showed a progressive fall in complement-fixation to less than 60 per cent of the initial level, and 2 exhibited no significant changes. Three individuals showed a rise in titer although in 1 case this was preceded by a preliminary fall. Flocculation tests were done in 10 of these individuals. An increase in Kahn units was noted in 7 patients, in 4 of whom a subsequent fall occurred. No changes appeared in 3 individuals, 2 of whom had likewise shown no change in complement-fixation titer.

Graphic illustrations of the serologic changes during therapeutic malaria in 4 patients selected from the above groups, together with accompanying descriptive legends, are presented in Figures 1, 2, 3, and 4.

In the control observation group, of 50 patients treated with fever induced by intravenous typhoid vaccine combined with intensive arsenotherapy, only 14 exhibited a fall in complement-fixation titer to 60 per cent or less of the initial level. Seven patients showing a drop in titer were among the 25 with central nervous system syphilis and the remaining 7 were of the 25 with latent syphilis. Of 25 patients with latent syphilis who received only intensive mapharsen therapy by the intravenous drip technic, only 2 exhibited a significant drop in complement-fixation titer during the period of therapy. Increases in complement-fixation titer were noted in only 10 per cent and 8 per cent of these two control groups respectively.

In Table 4 is presented a summary of the serologic changes in the several treatment groups. No differentiation between the patients with latent and central nervous system syphilis is made because of the similarities in the serologic changes as noted above.

The 6 patients in the *P. malariae* group who had been vaccinated with *E. typhosa* antigen a few weeks prior to inoculation showed no significant variation in *E. typhosa* agglutination

TABLE 4
Summary of Major Serologic Trends in Syphilitic Individuals during Various Methods of Therapy

titer during the course of the malarial infection although 5 of the 6 showed considerable falls in the titer of the complement-fixation tests for syphilis.

COMMENTS

The importance of the serologic method in demonstrating alterations in reagin content has previously been demonstrated by Kitchen, Webb, and Kupper, and more strikingly by Burney, Mays, and Iskrant in their studies showing the development of false positive reactions for syphilis in non-luetics during therapeutic malaria. Kitchen and his collaborators noted definite differences in the results of the flocculation and complement-fixation tests done upon individual specimens during the course of either *P. vivax* or *P. falciparum* infections. Burney, Mays, and Iskrant, employing 9 different technics, found marked variations in the frequency of false positive reactions for syphilis during the course of vivax infections, some tests exhibiting few or no positive reactions whereas others showed positive reactions among each of the 11 individuals studied. In the recently published report of the Washington Serology Conference,⁹ wherein different laboratories performed individual tests, considerable variations were again noted, the different technics giving positive results in from none to 75 per cent of the 12 cases of malaria tested. Differences in reagin appearance relative to the species of parasite used was noted by Kitchen, Webb, and Kupper, who observed that vivax infections tend to induce a greater proportion of positive serologic results during the course of the disease than did falciparum infections.

Our observations show that definite trends in the quantitative serologic tests occur in syphilitic individuals during the course of induced *P. malariae* infection, but that the direction of the trends is dependent upon the serologic

test employed. The different curves presented by the quantitative complement-fixation and flocculation tests for syphilis would appear to be governed by the specificity of the individual methods. The New York State complement-fixation test has previously been shown to possess high specificity. In the Washington Serology Conference referred to above this test revealed only one doubtfully positive reaction among 12 patients with malaria. Our results with quartan malaria seem to confirm this specificity as none of our patients showed an increase in titer over that recorded before inoculation with *P. malariae*. The downward trend of the complement-fixation titer may represent the development of an actual anti-reagin agent or of a factor which interferes with the demonstration of reagin by this method. In either case the depression in titer does not seem permanent as in several patients who have been followed sufficiently long the titer tends to approach its original level after a few months. No patients have been followed long enough to warrant any conclusion regarding a possible relationship between the depression in titer and the therapeutic results.

The most common trend of the Kahn and New York State flocculation tests during quartan malaria was a sharp rise in titer followed by a fall to or below the initial level usually before the termination of the infection. Based upon the work of others^{1, 2} the preliminary rise in titer would appear to be consistent with the development of a false positive test for syphilis in non-luetics during malarial fever and would indicate that the two flocculation tests are not quite so specific as the New York State complement-fixation test. In the syphilitic patient this probably represents a false positive reaction superimposed upon a true positive reaction. The tendency of the titer to fall

during the course of the infection differs from the trend noted among non-luetic in whom the newly acquired positivity often persists for 1 or more weeks after the last paroxysm. It is interesting and possibly significant that, of the 14 syphilitic patients who exhibited a rise in flocculation titer, the only 2 who failed to show a subsequent fall had also failed to show a fall in complement-fixation titer.

The trends of the serologic tests noted among the syphilitic patients treated with *P. vivax* infection were not nearly so consistent, although in the majority of patients the findings were similar to those exhibited by the *P. malariae* group. The occurrence of a rise in complement-fixation titer in 3 of the 11 patients seems to stress the importance of the species of parasite upon the serologic response, as Kitchen, Webb, and Kupper have noted (vide supra).

Ellingson and Clark¹⁰ have recently reported experiments demonstrating a rapid reduction in *E. typhosa* antibody titers in typhoid vaccinated rabbits following the induction of severe fever by physical methods. However, fever as a major influence upon the serologic titers in our patients appears to be eliminated by the results of the control groups. Only 28 per cent of the patients treated by fever induced by intravenous typhoid vaccine showed a fall in complement-fixation titer although the febrile bouts in this group were similar in intensity and duration to those observed in the *P. malariae* group in which such a fall was noted in 91 per cent. In addition, at least one instance was observed in which a fall in titer was first noted during the incubation period of quartan malaria prior to the first paroxysm. Arsenotherapy given by the intensive intravenous mapharsen drip appeared to have little effect upon the serologic titers, as significant changes during the

course of treatment occurred very infrequently in patients receiving this type of therapy alone.

Kopp¹¹ has reported the occurrence of marked changes in the plasma proteins in patients with therapeutic malaria. His patients exhibited significant depressions in albumen and usually slight elevations in globulin and fibrinogen, with all factors returning to normal upon termination of the infection. In some cases, the changes were noted before the onset of fever. Fever produced by typhoid vaccine or by the inductotherm caused only slight fluctuations in the plasma protein fractions. Whether these changes in plasma protein bear any relation to the fluctuations in reagin observed in our patients is a matter of speculation.

Our studies on the effect of *P. malariae* infection on induced typhoid antibodies revealed no change in the agglutination titer for *E. typhosa* during the malarial infection, indicating that the effects of this therapeutic method upon the tests for syphilis do not universally extend to other types of serologic reactions.

Interesting in this regard are the studies of Caldwell¹² who, in 1930, noted that the serum of general paralytics who had been treated by induced malaria had a higher titer of agglutinins for cultivated *Treponema pallidum* than the serum of similar but untreated patients. He also noted that an increase in spirocheticidal properties of the serum developed during the course of induced malaria in 6 patients. However, in their studies on the complement-fixation test using cultured spirochetes as antigen, Eagle, Mays, Hogan, and Burney¹³ and Kolmer, Kast, and Lynch¹⁴ found that a high percentage of non-syphilitic persons with natural or induced tertian malaria exhibited false positive reactions by this method. Further studies on the relationship between syphilitic reagin and spirochetal

antibodies are necessary before any correlation can be made between Caldwell's findings and our own.

Recently Dulaney, Stratman-Thomas, and Warr¹⁵ have described the development of high complement-fixation titers for malaria in syphilitic individuals treated with induced infection. Because of the importance of exact details concerned in any one serologic test in influencing the resulting titers it is not possible to compare the results of any procedures not done in identical manner. However, it is interesting that the specific or malaria complement-fixing antibody should be shown to increase while the reagin indicated by the New York State complement-fixation tests decreased.

SUMMARY

1. Changes in quantitative serologic tests in syphilitic individuals during the course of therapeutic malaria depend upon the type of test employed and the species of parasite used.

2. During infection induced by inoculation with *Plasmodium malariae* there was a uniform fall in the New York State complement-fixation titer and a preliminary rise and subsequent fall in the Kahn and New York State precipitation titers. During infection induced by inoculation with *Plasmodium vivax* the serologic changes were most often similar but were not so constant.

3. Fever alone did not seem to be a major factor in the production of the serologic changes.

4. No conclusions are warranted re-

garding any relationship between the changes in serologic titers and potential therapeutic results.

Effect of the Activated Sludge Process of Sewage Treatment on Poliomyelitis Virus*

HARVE J. CARLSON, M.S.P.H., GERALD M. RIDENOUR,
PH.D., AND CHARLES F. MCKHANN, JR., M.D.,
F.A.P.H.A.

Department of Pediatrics and Communicable Diseases, University of Michigan Medical School and the Department of Public Health Engineering, University of Michigan School of Public Health, Ann Arbor, Mich.

THE demonstration by several investigators¹⁻⁷ of poliomyelitis virus in the stools of patients and healthy carriers and in sewage leads to a question of the ultimate fate of the virus in its passage through modern water and sewage treatment processes. The question is of more than ordinary interest in view of the thesis⁸⁻¹¹ that the transmission of the disease may be through the gastrointestinal tract. This suggestion would throw suspicion upon water supplies as possible hazards in the spread of the disease. Protection against such a potentiality would depend upon the ability of water purification and sewage treatment processes to remove or to destroy the virus.

The first of a series of studies on the effect of water and sewage treatment on the virus was recently presented¹² in the form of a preliminary report of the efficacy of individual water purification units. The present communication is a report of the effect on the virus of the activated sludge process of sewage treatment.

METHODS

General—A strain of poliomyelitis virus adapted for mice was used throughout the experiments. The virus suspension employed in the experiments was prepared from cords and brains of mice killed in the acute stage of the disease and showing paralysis in two or more extremities. These tissues were ground in refined silica and suspended in buffered broth, 1:5. The supernatant from this concentrate was then made up with activated sludge to a dilution of 1:300. Such a heavy inoculum was used in order to ascertain the effect of activated sludge under severe loading with the virus. Furthermore, it was deemed desirable to use quantities of virus that could be readily detected.

The method of investigation consisted of observing the effect on the virus of the activated sludge process under conditions designed to simulate operating conditions usually encountered in this type of sewage disposal practice.

The activated sludge used in the experiments was obtained from the Ann Arbor Sewage Treatment Plant and showed the following chemical and biochemical characteristics:

* This study was aided by a grant from the National Foundation for Infantile Paralysis, Inc.

Ash—16%
 pH of mixed liquor—6.8
 Biochemical oxidizing power—90% removal of 5 day B.O.D. in 6 hours
 Suspended solids removal—95%
 Nitrate—nitrogen produced—15 p.p.m.

Before introducing the virus suspension, the activated sludge was aerated in the laboratory for 24 hours.

The activated sludge, inoculated with virus suspension, consisting of one part concentrated virus suspension to 300 parts mixed activated sludge liquor, was aerated for periods up to 9 hours. Samples were taken from the aeration units at 2 minutes, 3 hours, 6 hours, and 9 hours to represent different detention periods. These samples were allowed to settle and were then centrifuged and portions of the supernatant liquor were inoculated intracerebrally into mice. Concentrations of activated sludge in amounts of 1,100, 2,200 and 3,300 p.p.m. were studied separately in the above described manner.

Aeration Units—The aeration units used in the experiments are shown in the diagrammatic sketches in Figure 1. The unit appearing in the left of the

figure was used in several of the early studies and in the check runs of the investigation. The air entered through the base of the unit into a carborundum ball which dispersed the air throughout the mixture. The degree of dispersion was sufficient to keep the mixture agitated so that all portions were thoroughly aerated. In the second unit the air was introduced through a tapered glass tube placed at the bottom of a liter glass cylinder. The end of the glass tube was narrowed to a small orifice allowing only a fine stream of air to emerge. This method proved to be very efficient both in aeration and in mixing of the sludge.

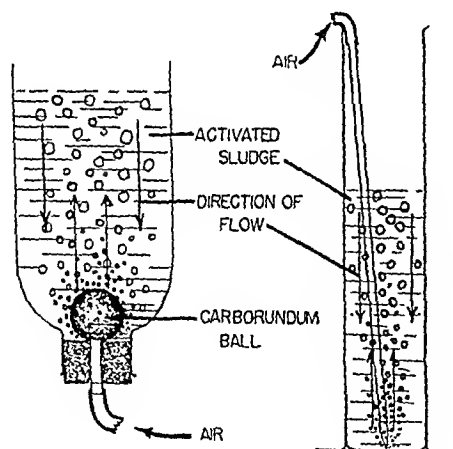

Both units were operated at a rate sufficient to maintain aerobic conditions in the mixture.

The amount of settleable solids were varied to approximate different conditions. The various concentrations of activated solids used were obtained by concentrating two to three times the material obtained from the municipal sewage disposal plant. Control measurements of the activated sludge included repeated determinations of suspended solids, total ash, pH, titrable acidity or alkalinity, ammonia-nitrogen and nitrate-nitrogen.

Sampling—In collecting the samples at consecutive aeration intervals, portions of the supernatant were removed aseptically by suction. The samples were then centrifuged to remove the coarser particles that were impossible to eliminate by the method used in collecting the supernatant liquor. Comparisons were made between centrifuged specimens and gravity-settled specimens; the final results were supernatant liquors of comparable quality. Centrifugation, however, speeded this phase of the work.

Bactericidal treatment—In order to obtain an effluent free from bacteria that might cause complications and death in the animals, the supernatant

FIGURE 1.

ACTIVATED SLUDGE - AERATION UNITS

liquor was treated with chlorine. The addition of chlorine in sufficient concentrations to destroy interfering bacteria was demonstrated not to affect the virus. The bactericidal process consisted of treating the samples to be used for inoculation with chlorine in such quantity that 0.5 p.p.m. residual chlorine was present at the end of 10 minutes' contact time. Residual chlorine was determined by the starch iodide method. All control and activated sludge samples were treated in the same manner.

RESULTS

Paralysis in one or more mice in any test group was deemed to be indicative that the virus was not removed or destroyed by the activated sludge in which it was suspended. Animals dying 1 to 3 days after inoculation were considered to have died from trauma or interfering toxic substances. Those dying without showing paralysis after the first animal in any group had become paralyzed were considered to have died probably from the virus infection, with respiratory paralysis causing the death before paralysis was observed in the extremities. However, in the statistical interpretation of the results, nonparalyzed animals were counted as having succumbed to the virus only if the presence of the virus in each animal so dying could be checked by subsequent passage.

The possibility of the presence of an extraneous virus of neurotropic type in the activated sludge itself had to be considered. This possibility was controlled in all the experiments through inoculation of samples of the supernatant from the activated sludge intracerebrally into test groups of animals. At no time throughout the experiment were results obtained indicative of the presence of such a virus.

The results of the study are shown in Table 1. Four hundred and twenty mice were used in the final experiments with a total of 1,150 animals used al-

together including preliminary studies and various check runs. In Table 1 are shown the results in the control animals and in animals receiving virus suspension subjected to action of three different activated sludge concentrations for three periods of aeration. Three types of control were used. Two of the control series (Nos. 1 and 2 in Table 1) consisted of animals that received the original 1:5 brain cord virus suspension and the 1:300 suspension, the latter equivalent to the dilution used in the activated sludge tests. These dilutions were injected into mice to determine the potency of the virus used. The third control (No. 3) consisted of a group of animals that received the 1:300 suspension of virus subjected to aeration but without addition of activated sludge. This control served to indicate the effect of aeration alone in the absence of any effect of the sludge. Nos. 4, 5, and 6 in the table represent the effect of three different concentrations of activated sludge for different aeration periods.

In the six groups of 30 animals each that received virus-sludge mixture without aeration, 84 were paralyzed, 39 died without showing paralysis, and 58 remained alive of the total of 180 animals. Twenty-one of the 39 deaths were deemed to be due to trauma since the animals died within the first 3 days after inoculation.

It is to be noted that in the material subjected to aeration for 6 hours, paralysis occurred only in the control group of mice that received material subjected to aeration but containing no activated sludge. Although a few animals died that received virus-sludge mixture after aeration, the numbers are small and the preponderance of survivals is very great. The results are even more striking in the group of 120 mice that received material aerated for 9 hours. Here again paralysis occurred only in those animals that received virus

TABLE 1

No.	Suspended Solids p.p.m.	No. Mice	Hours									Material Used for Inoculation
			0 Hours			6 Hours			9 Hours

1	0	30	24	6	—	Virus control 1-5 non-aerated
2	0	30	18	4	8	Virus control 1-300 non-aerated
3	0	90	14	6	10	11	10	9	7	3	20	Virus control 1-300 aerated
4	1,100	90	8	12	10	0	6	24	0	1	29	Virus 1-300 — Activated sludge plus aeration
5	2,200	90	13	5	12	0	3	27	0	1	29	Virus 1-300 — Activated sludge plus aeration
6	3,300	90	7	6	17	0	1	29	0	1	29	Virus 1-300 — Activated sludge plus aeration

P = Animals paralyzed

D = Animals dying without developing paralysis

Dis = Animals remaining alive

suspension subjected to aeration in the absence of activated sludge. Of the 90 animals receiving virus-sludge mixture subjected to 9 hours' aeration, none became paralyzed and only 3 died in the course of the experiment.

DISCUSSION

Although the difficulties encountered in rendering activated sludge mixtures nontoxic for animals may account for the death of some animals, the study of the results of these experiments indicate that activated sludge in concentrations as low as 1,100 p.p.m. has largely removed the virus (as tested for in the supernatant liquor) in a 6 hour aeration period, and that the sludge in amounts of 1,100, 2,200, and 3,300 p.p.m. at 6 and 9 hours' aeration periods removed the virus sufficiently from the liquor to make it almost completely noninfective when injected intracerebrally into mice.

The sludge without prolonged aeration appeared to have no great affinity for prompt adsorption of the virus. In the series of animals tested, 14 mice of the control group of 30 animals were paralyzed against 8, 13, and 7 respectively in the similar groups that received virus after exposure to the three concentrations of sludge. The effect of

aeration without the presence of activated sludge is shown in Line 3 of Table 1. Virus removal or inactivation may have been effected to some degree by prolonged aeration since the number of mice paralyzed decreased from 14 in the group of 30 receiving nonaerated virus suspension to 7 in the group that received virus suspension aerated for 9 hours. Aeration of the virus suspension in dilution of 1:300 caused some precipitation of the protein material so that after the 6 and 9 hour periods there appeared an accumulation of shreds (brain and cord protein) floating on the surface or adhering to walls of the aeration units. This may have been responsible for removal of some of the virus.

The mechanism of removal or destruction of poliomyelitis virus in the activated sludge process of sewage treatment is not clear. Further experiments are needed to determine what proportion of the action of the sludge on virus may be due to adsorption in a mechanical fashion, to partial precipitation by aeration, or to virucidal, oxidative, or enzymatic activity of the sludge.

SUMMARY

Investigations have been made of the effect of the activated sludge process as used in municipal sewage disposal

plants on the removal or inactivation of a mouse adapted strain of poliomyelitis virus. Virus suspension 1:300 was used in sludge concentrations of 1,100, 2,200, and 3,300 p.p.m. with aeration periods of zero, 6 and 9 hours.

The results indicate that activated sludge in amounts as low as 1,100 p.p.m. with 6 hours' aeration will remove or inactivate the virus to a sufficient extent to reduce greatly infectivity for mice injected intracerebrally. Heavier concentrations of sludge with longer aeration periods largely eliminate infectivity.

Tuberculosis Survey among the Employees of Santiago, Chile*

BENJAMIN VIEL, M.D., M.P.H., AND EDUARDO A. JELIC, M.D.

*Direccion General de Sanidad, Santiago, Chile; and Tuberculosis Department of
the Caja de Empleados Particulares, Santiago, Chile*

THROUGH the efforts of the then Minister of Social Welfare, Dr. E. Cruz Coke, the Preventive Medicine Law was passed in 1938.

This is an official compulsory health insurance for private employees. It covers a middle class group made up of employees in commerce and the professions whose duties are chiefly intellectual and who receive their remuneration from private capital but are not covered by Labourers Insurance.

The operation of the Law is made possible by a 2 per cent tax on salaries, shared equally by employee and employer. The law provides for the annual physical examination of employees and free treatment for those who are found to have tuberculosis, syphilis, or circulatory disease in a curable form.

Offices and a special medical staff have been provided for carrying on examinations and treatment. The staff includes a group of internists, who take the history and make the general physical examination of the employee; a laboratory group; x-ray group; and specialists in tuberculosis, syphilis, and circulatory diseases. The employee has a routine history, physical examination, Wassermann and Kahn blood tests, and fluoroscopic examination of the

chest. If he shows signs of tuberculosis, syphilis, or a circulatory disease, he is transferred to the specialist for a more complete examination. A special effort is made to detect tuberculosis and, although fluoroscopy is used, there is no hesitancy in having a roentgenogram if there is any suspicion of a lesion. In fact, of all employees examined 30 per cent had chest plates taken.

In the first two and a half years of the Law's operation in Santiago, 68,854 persons were enrolled and insured. Of these, 25,556 were given a physical examination. Ages ranged from 16 to 65 years, and 75 per cent were men. Of the 25,566, 899, or 3.51 per cent, were found to have lesions of active tuberculosis, and 1,113, or 4.35 per cent, had signs of residual tuberculosis.

In Table 1 the group of employees examined is distributed according to age and sex and the number and percentage of those with active lesions is shown. The curve reaches its peak in the age group 20-29 and then descends rapidly through the upper age groups. If we compare this curve with our general tuberculosis mortality curve by ages, we see that their peaks coincide at the same age, but while the morbidity curve decreases rapidly, the mortality curve drops more slowly and, in fact, remains almost at the same level. We think that tuberculosis mortality after the age of 40 is due in great part to chronic tuberculosis incompatible

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

TABLE 1
Employees Examined by Age, Sex and Active Tuberculosis

	Men	Women	Total	Men	Women	Total	Men	Women	Total
16-20	966	503	1,469	43	17	60	4.45	3.41	4.08
20-29	7,075	3,638	10,713	316	198	514	4.47	5.45	4.79
30-39	5,854	1,768	7,622	151	59	220	2.75	3.32	2.89
40-49	3,238	475	3,713	68	11	79	2.11	2.32	2.13
50 and over	1,913	136	2,049	16	0	16	0.84	0.0	0.78
Total	19,046	6,520	25,566	604	285	889	3.17	4.37	3.51

with an active life. Those individuals whom we examined were active workers with perhaps less chronic tuberculosis than the general population; hence, the apparent discrepancy between our curves of morbidity and mortality.

In contradistinction to our findings the tuberculosis mortality rate curve of white North Americans ascends progressively with age. Manuel Abreu found the same condition in the survey which he made of employees in Brazil in which the proportion with active tuberculosis lesions increased with age.

This difference between the Chilean curves of mortality and morbidity and those of other countries may indicate that we are passing through an epidemiological phase of maximum infection in which the disease has not yet shown a tendency to decrease spontaneously.

With regard to sex there is noted a higher morbidity among females during the reproductive period. Probably the phenomena of the sexual life of the

woman, such as menstruation and pregnancy bring about modifications in the defense mechanisms against infection.

The economic situation of this group can only be studied indirectly, that is, by grouping all private employees of Santiago according to daily wage, and then comparing the percentages of the 899 cases in each of these income divisions. This is shown in Table 2.

U. C. D. is the amount of money received per person per day. It is obtained by dividing the monthly income by 30, and that amount in turn by the number of individuals in the family.

If the income has a definite influence on morbidity rates we should expect to find these rates higher among the lower income groups. This, however, is not the case and, as we note in the above Table 2, there is a higher proportion of cases among those receiving more income per capita. Forty-three per cent of the cases were in the higher income group which made up only 23 per cent of the group studied.

Since these observations contradict our belief that the incidence of tuberculosis is influenced by the economic factor, it is necessary to make a more detailed study of a larger group of people than those included in this particular work. In order to obtain a more complete picture in Table 3 we have divided the provinces of Chile into groups according to the average salaries paid during the year 1939. In these

TABLE 2
Percentage of 889 Cases in Each Economic Group

U.C.D. (pesos)	Per cent of Active Cases	Per cent of Employees of Santiago
Less than 4.10	16.1	17.3
4.10-10.40	41.3	59.5
10.50-20.80	32.0	15.6
20.80 and over	10.6	8.6
Total	100.0	100.0

U.C.D. = Average daily salary per household member
One Chilean peso is equal to \$0.03

TABLE 3

Provinces of Chile according to Average Salary Paid

<i>Weekly Salary (Dollars)</i>	<i>Provinces</i>	<i>Average Mortality Rate from Tubercu- losis (1937-1938)</i>	<i>Average Infant Mortality Rate (1937-1938)</i>
More than \$3.00	Magallanes, Coquimbo, Atacama, O'Higgins	253.5	188.5
From \$2.28 to \$2.97	Antofagasta, Tarapaca, Santiagn, Valparaiso, Malleco, Aysen	271.4	206.6
From \$1.86 to \$2.25	Cautin, Colchagua, Aconcagua, Mnule, Concepcion, Arauco, Bio-bio, y Curico	197.0	261.6
Less than \$1.86	Linares, Valdivia, Talca, Nuble, Llan- quihue, y Chilo	190.0	271.8

groups of provinces we have obtained the tuberculosis mortality rates. Infant mortality rates, since they are our best statistical indication of economic status, have also been included. The highest infant mortality rates are in those provinces with the lowest income. The tuberculosis mortality rates, however, as in the previous table, are higher in those provinces where economic conditions are better.

It is interesting to note that Abreu in a similar study of municipal employees in Brazil found the same condition as in Chile with a higher percentage of active cases among the upper income groups. This is illustrated in Table 4.

TABLE 4

*Tuberculosis among Municipal Employees in
Brazil Classified according to Salary
(From Dr. Manoel de Abreu)*

<i>Monthly Salary (dollars)</i>	<i>Per cent of Active Tuberculosis</i>
\$17.75	2.38
\$31.50	3.00
\$45.00	2.07
\$60.00	4.82
\$60.20 and over	3.28

From these observations we are inclined to conclude that tuberculosis morbidity is not influenced by financial income in Chile. Probably the idea

that tuberculosis is an economic disease is due to the fact that the prognosis varies directly with the economic status of the patient.

TABLE 5

Per cent of Healed Classified by Salary

<i>U.C.D. (pesos)</i>	<i>Per cent of Healed</i>
Less than 4.10	52.4
4.10 to 10.40	66.5
10.50 to 20.80	68.2
20.90 and over	76.2

In order to determine the relationship of economic status and response to treatment, we have divided the persons treated into two groups, those who showed a favorable response, and those who showed no improvement. Table 5 gives the percentage of favorable responses to treatment in each of the various income per person per day groups, and illustrates clearly the higher number of cures among the upper income patients.

From these observations we are inclined to think that many individuals of good economic status having tuberculosis lesions without symptoms are cured spontaneously while many of those whose standard of living is lower become progressively worse. (Logically in this survey in which the majority of the lesions discovered are producing no

symptoms, the percentage of active lesions does not vary with the economic status of the groups examined.)

Unfortunately, the Preventive Medicine Law does not provide for the examination of family contacts, and for this reason it is impossible for us to investigate the relationship of economic status to communicability. It is only possible for us to group the individuals studied according to diagnosis and then compare these groups with reference to history of contact.

In Table 6 we have considered the individuals to have a history of contact if in their families there was an active case of tuberculosis under the care of a physician or a death from tuberculosis in recent years. This analysis demonstrates the importance of the contact factor in the spread of the disease. Attention is called to the fact that 16.7 per cent of those found with active lesions gave a positive history of contact, while only 0.9 per cent of those with no lesions gave such a history. This figure is similar to that obtained by us in the study of a small group of families of patients hospitalized for tuberculosis, in which we found 23 per cent of family contacts with active asymptomatic lesions. Professor Sayé in a recent investigation in Chile found that 22 per cent of individuals in familial contact with open cases of tuberculosis showed active lesions. (This high figure demonstrates the im-

portance of carrying antituberculosis activities to the family of the patient.)

TABLE 6

History of Exposure to Open Cases

<i>Diagnosis</i>	<i>Persons Examined</i>	<i>Per cent with Contact History</i>
Healthy	20,351	0.9
Residual Tuberculosis	1,316	9.1
Active Tuberculosis (Minimal and Moderately Advanced)	645	16.3
Far Advanced Tuberculosis	36	25.7

Residual tuberculosis is lesions without clinical significance and so these persons were not included among the tuberculous cases in Table 1.

The difference in the number of persons examined between Table 1 and Table 6 can be explained because we could not find any reference about exposure in 208 of the patients and in 3,000 of those classified as healthy, residual or not.

From Table 6 it is easy to see how much more important is the contact factor than the economic factor in the prevalence of tuberculosis in Chile. Unfortunately, tuberculosis has been looked upon as an economic disease, and for this reason the problem has been taken up by politicians and has been attacked chiefly by the economist rather than the epidemiologist.

Of the 889 individuals diagnosed as having active tuberculosis it is possible at this time to present figures on 461 closed cases. Of these 461, the first diagnosis was minimal lesion 178, moderately advanced 196, and far advanced 87. In Table 7, these are classified according to their condition at the time of discharge. The more advanced

TABLE 7

Stage at Time of Discharge Classified according to First Diagnosis

<i>Status at Discharge</i>	<i>First Diagnosis</i>		
	<i>Minimal</i>	<i>Moderately Advanced</i>	<i>Far Advanced</i>
Cured	162	122	4
Improved	11	30	11
Unchanged	2	23	45
Worse	3	21	27
Total	178	196	87

Deaths are not included because those who become worse or are unchanged after a reasonable period of time are discharged, and the Service does not know anything more about them.

The people classified as improved are those considered cured but without the gastric lavage which can prove it.

the disease at the time of discovery, the less favorable was the outcome.

In Table 8 this group of patients is classified according to progress of infection in relation to age. Although it appears that the percentage of cured or improved is higher among the lower age groups, the numbers in the upper ages are too small for comparison.

If we classify those who were discharged as cured we find that the average period of treatment for those with minimal lesions was 12.6 months, whereas those with moderately advanced lesions were treated 17.1 months, and those with advanced lesions 19.5 months.

This study gives us a clear idea of

TABLE 8
Stage at Discharged Classified by Age

Age	Cured	Per cent	Improved	Per cent	Unchanged	Per cent	Worse	Per cent
Less 20	22	64.7	5	14.7	3	8.5	4	11.7
20-29	183	67.0	31	11.3	29	10.6	30	11.0
30-39	62	59.6	12	11.5	21	20.2	9	8.6
40-49	20	50.0	2	5.0	14	35.0	4	10.0
50 and over	2	20.0	0	5	50.0	3	30.0
Total	289		50		72		50	

In studying the care received we find that 81 per cent of those treated in a sanatorium showed improvement, as against 70 per cent of those treated at home. The difference is probably significant as sanatorium cases were selected from those with a less favorable prognosis. There is no difference between the percentages of men and women who showed improvement under treatment.

the economy in cost of treatment obtained by discovering cases in the early stages of the disease.

This report is only in the nature of a preliminary communication. It is an attempt to pause for a moment and take stock of what is being done with the hope that we may correct errors and direct our steps toward bringing about the best possible results.

Public Health and Economic Aspects of Pneumonia—A Comparison with Pre-sulfonamide Years

HARRY E. UNGERLEIDER, M.D., F.A.P.H.A., HENRY W. STEINHAUS, PH.D., AND RICHARD S. GUBNER, M.D.

Equitable Life Assurance Society of the United States, New York, N. Y.

THE spectacular results which have attended the use of sulfonamide drugs in pneumonia have simplified therapy of a disease, which until a few years ago called for the exercise of all the therapeutic resources and ingenuity at the physician's command. Inevitably, this has led to an attitude of almost casual optimism. While the prognosis in the individual case has improved tremendously, the present study, undertaken to determine what influence the newer therapy has had on public health and economic aspects of pneumonia, emphasizes that pneumonia remains a major problem in public health.

Valid morbidity data are notoriously difficult to obtain. Analysis of pneumonia experience among the personnel of several large industrial organizations carrying group health and life insurance with the Equitable Life Assurance Society of the United States, appeared to provide a satisfactory method whereby the prevalence of pneumonia and certain other aspects could be studied. The groups reviewed comprised a large number of diversified industries throughout the United States, totalling over 100,000 employees of average industrial age distribution (Table 1). The findings, therefore, may be considered representative of the entire industrial population, rather than

reflecting the particular trend in any one industry, age group, or locality. All cases of pneumonia were included in the analysis excepting those where pneumonia occurred terminally or as a complication of another disabling illness. The recent report on "A Nationwide Study of the Bacterial Etiology of the Pneumonias"¹ indicates that pneumococci are responsible for more than three-fourths of all pneumonias.

In order to ascertain what influence the advent of sulfonamide therapy has exerted on the prevalence, mortality,

and duration of illness in pneumonia, the years 1935 to 1937 inclusive were compared with the period from January 1, 1939, to June 1, 1942. The year 1938 was not included since this was a transition period when sulfonamide therapy was being introduced in the treatment of pneumonia. The average exposure in the first period was 100,364 lives, and in the second period 123,962 lives.

INCIDENCE

The frequency of pneumonia by quarters and years is indicated in Table 2. The incidence of pneumonia, as revealed in studies conducted by The U. S. Public Health Service,² is shown for comparison. The public health data are comparable to our findings, being based similarly on pneumonia experience among large industrial groups throughout the United States.

The findings in both studies are graphically summarized in Figures 1 and 2.

It is observed that the incidence rates and trends in both series check quite closely. The over-all average shows an incidence rate of 2.6 per 1,000 in the first period (pre-sulfonamide), compared with 3.0 per 1,000 in the second period. The public health data show an incidence rate of 2.6 per 1,000 in the first period, and in the second period a somewhat greater increase to 3.4 per 1,000.

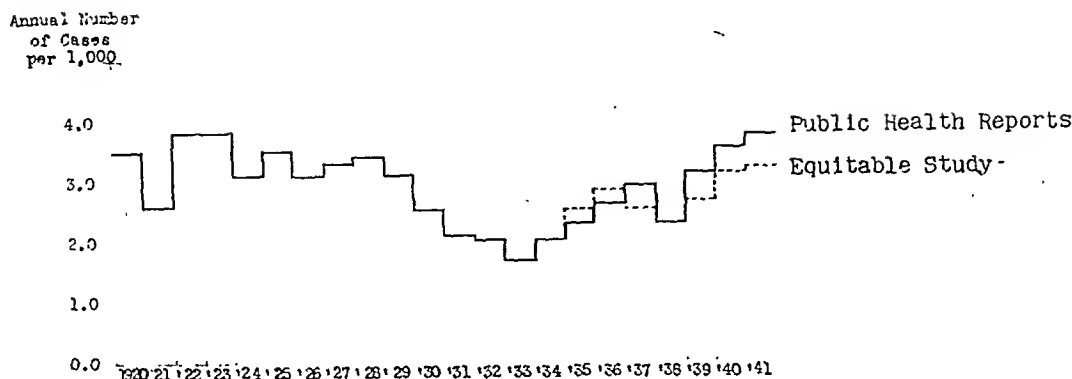

An increase in the incidence of pneumonia since 1939 is evident in both series and is much more striking in the public health survey. The greater increase in the public health survey, however, may be apparent rather than real for the public health study includes only pneumonia cases of over 8 days' duration, so that no cases with a fatal

ANNUAL RATES OF PNEUMONIA INCIDENCE
CALENDAR YEARS 1920-1941 INCLUSIVE

termination within the first 8 days of illness are included. Thus, the increased number of cases since the introduction of sulfonamide treatment recorded in the public health survey is to be attributed, probably in major degree, to a greater number of cases which now survive. Previously a much greater percentage of cases terminated fatally in less than 8 days and, accordingly, were not listed in the public health survey. In the Equitable data all fatalities in both periods, including deaths within the first 8 days of illness, are included so that the comparison of incidence rates is more valid.

While the omission of fatalities in the public health data invalidates any comparison of incidence rates with pre-sulfonamide years, nevertheless, it is of interest to review the annual incidence of pneumonia prior to 1938. The public health data prior to 1938 may serve in some measure to reflect changes in incidence, even though fatal cases were not included, since the mortality rate did not vary greatly before 1938, although a slight gradual decline in the mortality rate had been manifest for some years probably due to increasing use of oxygen and serum therapy. The annual incidence rate per 1,000 as far

back as 1920 and quarterly rates since 1929 have been abstracted from the periodic public health reports of disabling morbidity among industrial employees, and are presented in Table 3. It is seen that, even excluding deaths in the first 8 days of illness, the incidence of pneumonia was at least as high as, or higher than, the present rate in the decade from 1920 to 1930. Inclusion of fatal cases would raise the annual rates in this period by at least another 20 to 25 per cent so that it must be concluded that pneumonia is no more prevalent, and probably less so, than it was at that time. It is rather interesting to note that during the depression years of 1931 to 1935 pneumonia frequency was at its lowest among the employed. Interestingly enough a similar decrease in the incidence of pneumonia occurred in Sweden during these years.³ The gradual decrease in pneumonia incidence over the period of a decade from 1920 and its gradual rise again during the past 10 years suggests the possibility of a cyclic prevalence such as is known to exist in certain other infectious diseases. Some years ago it was suggested that a 3 year cyclic incidence rate exists for pneumonia,⁴ but this has not been sub-

1942	7.2	4.8

stantiated. The changing incidence^a is not sufficiently striking to give any credence to the hypothesis that the frequency of pneumonia varies in any regular manner over a period of time. Although a cyclic incidence of pneumonia cannot be claimed, the variation in incidence rates which are seen to have existed prior to 1938 indicate that little specific significance can be attached to the increase in incidence of pneumonia to 3.0 per 1,000 during the past 3 years as compared with an incidence rate of 2.6 per 1,000 in the 3 year period preceding the use of sulfonamides.

CASE FATALITY RATES

Mortality studies are unanimous in revealing a marked decrease in the pneumonia death rate since 1938. The New York City death rate from pneumonia per 100,000 population over the past decade is summarized in Table 4.⁵ Analysis of pneumonia deaths among the industrial workers studied by us shows the death rate per 100,000 to be 54.7 for the period 1935 to 1938, compared with 11.9 for the period 1939 to June 1, 1942. The decrease in the industrial group is much more striking than in the general population. The death rate in both periods is likewise much lower in the industrial group than in the population as a whole; which is to be expected, since pneumonia death rates are highest at the extremes of life in age groups not included in the industrial population. It is of interest to note further that the death rate has fallen much more among the industrial age group than in the general population, suggesting that the sulfa drugs are of greatest benefit between the ages of 15 and 65. Beyond the age of 65 where pneumonia frequently is complicated by other serious illnesses, therapy with the sulfa drugs appears to be somewhat less efficacious.

TABLE 4

Source—February 1942 *Quarterly Bulletin* City of New York Department of Health

The effect on the annual death rate does not give an entirely valid expression of the changes in mortality wrought by the newer therapy, for account must be taken of any changes in incidence. In view of the fact that the incidence of pneumonia has increased since the introduction of the sulfa drugs the effect on mortality is even more striking than is indicated by the gross annual mortality rates.

The true measure of the benefit resulting from sulfonamide therapy must be evaluated by its effect on case fatality rates and not by gross mortality figures which are influenced by and take no account of changes in incidence. Analysis of the case fatality in the series here reported revealed a mortality of 20.8 per cent (± 1.5)* in the first period (1935 to 1937) and 3.9 per cent (± 0.5)* in the second period (1939 to June 1, 1942), indicating that a remarkable reduction in mortality has occurred since the introduction of sulfonamide medication. The case fatality of approximately 4 per cent is lower than the case fatality rates of 8 to 12 per cent reported in most series of hospitalized cases treated with sulfona-

* Standard Deviation

mides.^{6, 7} The present study, however, includes only cases of pneumonia between 15 and 65, and it is well known that mortality in this age group is less than at the extremes of life. Furthermore, a large percentage of these may not have been so seriously ill as to require hospitalization. Rosenthal, McCall, and Pratt recently reported a similar case fatality rate of 3.8 per cent in 132 cases treated in the home with sulfathiazole.⁸ The findings indicate that between the ages of 15 and 65 the case mortality rate in pneumonia is now of the order of 4 per cent. Stahle⁹ recently reported a case fatality rate of 6.82 per cent in an analysis of 6,321 cases with pneumonia between the ages of 13 and 60, who were treated with chemotherapy, and Plummer, et al.¹⁰ in a smaller series of cases under their observation reported a mortality of 3.4 per cent in patients between the ages of 30 and 50 who were treated with chemotherapy.

DURATION OF ILLNESS AND ECONOMIC ASPECTS

Clinically it is found that not only is the mortality favorably influenced by sulfonamides, but the course of the disease is greatly abbreviated. It is extremely rare to observe a classic crisis with modern treatment and most frequently fever subsides by rapid lysis within 36 to 48 hours. The period of hospitalization too has been greatly abbreviated. While pneumonia now responds rapidly to treatment in most cases, the total duration of disability remains not inconsiderable, and it is still several weeks before the average patient is ready to resume his activities.

The average duration of illness in terms of days away from work was 33 days in 1941, compared with an average work loss of 45 days in 1935. The modal or most frequent duration of illness in 1941 was 27 days compared with 38 days in 1935. The entire

period studied has as the average duration of non-fatal pneumonia illness 43 days in the first period (1935 to 1937) and 36 days in the second period (1939 to June, 1942). The shortening of illness is actually greater than would appear from these averages, for many previously fatal cases now survive to become illnesses of longer than average duration.

Illness is a more important cause of industrial absenteeism than any other factor, and respiratory tract diseases are responsible for more loss of time from work than all other illnesses combined. Pneumonia is relatively infrequent compared with other acute respiratory infections, such as colds and influenza, but since the average case results in approximately a month's loss of time from work, pneumonia becomes a factor of significance in itself. It is of interest to compute what savings have accrued to industry through the introduction of sulfa drugs.

Recent statistics indicate that there are approximately 52,000,000 gainfully employed persons in the United States.^{11, 12} Based on incidence and mortality rates of pneumonia established in the present study, it is calculated that the use of sulfa drugs in pneumonia is saving the lives of some 25,000 industrial workers annually and the considerable expense and time incident to replacing these workers in their specialized occupations. Had the incidence of pneumonia remained unchanged, the beneficial effect of the sulfa drugs in shortening the duration of illness would have resulted in a further annual saving of over 1,000,000 working days. However, since the incidence has increased the actual savings in working days actually is appreciably greater.

COMMENT

This study was undertaken to determine whether the widespread use of

sulfa drugs* has effected any change in public health aspects of pneumonia, such as prevalence, comparable with the striking changes observed clinically in the treatment of the individual case.

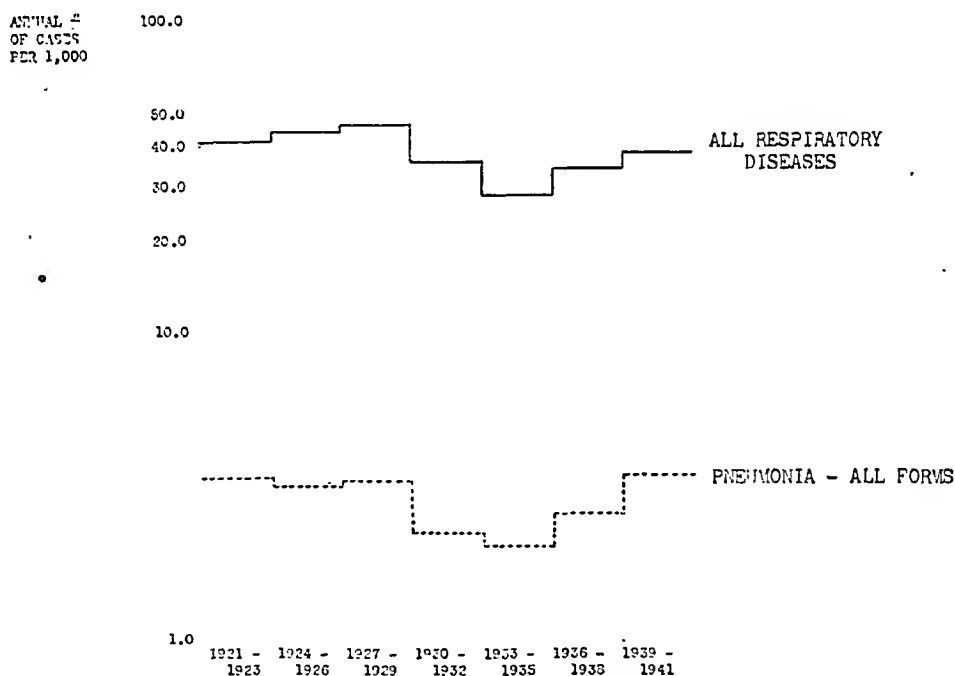

An increased frequency of pneumonia was not anticipated, and while not marked in degree, it is sufficiently definite to warrant analysis. The incidence of pneumonia in 1940 and 1941 was higher than in any year in the

certain other infectious diseases. It is well known that upper respiratory infections predispose to pneumonia and the high frequency of pneumonia immediately following the last war was undoubtedly due to the influenza pandemic at that time. The change in incidence of pneumonia from 1921 to 1938 paralleled very closely the yearly change in incidence of other respiratory diseases (Figure 3). However, in

FIGURE 3

RESPIRATORY DISEASES LASTING 8 CONSECUTIVE CALENDAR DAYS OR LONGER

(LOGARITHMIC SCALE)

Source: PUBLIC HEALTH REPORTS

preceding decade, but was no greater than the frequency rate in the preceding decade from 1920 to 1930. It is possible that the increased prevalence in the past few years reflects a cyclical change in incidence, although it has not been shown that any definite periodic fluctuation occurs in pneumonia as in

the past few years since 1938 an increase in the incidence of pneumonia has occurred out of proportion to a much lesser increase in prevalence of other acute respiratory diseases. The current high pneumonia rate, therefore, is not following passively in the wake of other respiratory illnesses and must be attributed to some other cause.

The increase in the number of cases of pneumonia cannot be ascribed to any improvement in the diagnostic acumen.

* A recent survey indicates that sulfonamide medication is employed in over 85 per cent of fatal cases of pneumonia, and is probably used in an even higher percentage of recovered cases.²⁴

In the case of coronary artery disease the tremendous increase in reported incidence undoubtedly has been due in large part if not entirely to improved methods of diagnosis such as the use of the electrocardiogram, but the signs of pneumonia have long been well known and it seems dubious whether x-rays have been employed as a diagnostic method to any considerably greater degree during the past few years.

Wartime living conditions may play a part in accounting for the increasing prevalence of pneumonia. The incidence of other infectious diseases, notably tuberculosis, has increased appreciably during the present war. It is quite likely that such factors as congestion in cities, inadequate housing, crowded transportation, long hours and irregular habits resulting from night shifts, inadequate medical attention, all may have contributed to a general increase in the prevalence of infectious diseases. The significance of crowding was revealed in the National Health Survey¹³ where it was found the pneumonia frequency rate was 6.7 for families with more than 1½ persons per room, as against 4.0 for families with 1 person or less per room. Benjamin, Rueggesser, and Senior have emphasized the hazard of overcrowding,¹⁴ and the occurrence of cross-infection¹⁵ in pneumonia. During the first week of illness the risk to household contacts has been estimated to be sixty times greater than in the general population. In a recent study on the epidemiology of pneumonia,¹⁶ Smillie and Jewett emphasized the spread of pneumonia in a closed community, finding a rapid spread of type 14 pneumococcus. This study suggested "that a virulent strain of pneumococcus may enter a community, permeate it, invade many individuals, and linger for a considerable time without causing any apparent illness. Some untoward factor may

then enter the picture (such as an acute respiratory infection) which will lower the resistance of the carrier of the virulent pneumococcus strain to such a degree that the strain will invade the tissues of the body and produce a serious illness."

One may note that a definite upswing in the prevalence of pneumonia was apparent in 1940 before any great economic or social dislocation had been brought about by the war. The tremendously increased industrial activity in the United States during the past few years has drawn numbers of older people into industry, which has been all the more accentuated by the withdrawal of young men into the armed forces. Many employees of advanced years are reluctant to admit their true age when obtaining employment so that there must be an even greater percentage of industrial workers of advanced years than would be indicated in a statistical tabulation. The incidence of pneumonia rises gradually from approximately 2.5 per 1,000 annually at age 20, to 6 per 1,000 at age 60, the prevalence increasing very rapidly thereafter beyond the age of 60.¹³ The observed increased prevalence of pneumonia may be due in part to an increase in the average age of industrial workers. However, the average age of the employees investigated in the present study remained fairly constant over the period from 1937 to 1941.

One may speculate whether the use of sulfa drugs has had any specific effect, *per se*, on the frequency of pneumonia. This is unlikely for several investigators have shown that the antibody response in pneumonia is not significantly altered by sulfa therapy,¹⁷⁻²¹ nor has it been found that there are more carriers following pneumonia in sulfa treated cases.²²

During the past year an increased number of cases of atypical pneumonia

have been observed which have proved refractory to sulfonamide treatment. A virus etiology has been demonstrated in some cases, but it would be a serious error to conclude that a new disease has suddenly become widely prevalent, and that all cases of pneumonia which fail to respond in the usual manner to the sulfonamides are examples of virus pneumonia. It has been shown that pneumococci may acquire a resistance to sulfonamide during treatment and that such organisms remain sulfonamide-fast in succeeding generations.²³ The frequent failure of sulfonamide therapy observed during the past year may represent instances of pneumonia due to sulfonamide-fast organisms, and a diagnosis of "atypical" or virus pneumonia should not be made until every effort has been expended to demonstrate pneumococci in the sputum. The cases of pneumonia which form the basis for the present report include all types of pneumonia and if it is true, as some believe, that the prevalence of virus pneumonia has actually greatly increased, this may account for the observed increased frequency of pneumonia. Since the mortality rate of virus pneumonia is very low, the inclusion of these cases may be a factor contributing to the very low mortality of 4 per cent observed in the present series.

SUMMARY

A study was undertaken to ascertain whether sulfonamide therapy has had any effect on public health aspects of pneumonia comparable to the remarkable changes observed in treatment of individual cases. An analysis was made of pneumonia experience among large groups of industrial employees carrying group health and life insurance with the Equitable Life Assurance Society of the United States, and a comparison was made between the pre-sulfonamide years 1935-1937 and the period from January 1, 1939, to June 1, 1942.

Most striking was the reduction in the case fatality rate from an average of 20.8 per cent to 3.9 per cent in this short space of time. Significant too was a decrease in the total duration of illness from the modal (most frequent) period of 38 days in 1935 to 27 days in 1941. It is calculated that the advent of sulfonamide therapy has proved a boon to industry, saving the lives of some 25,000 workers annually. A further annual saving of over a million working days has resulted from shortening of the period of illness.

The incidence of pneumonia has increased from an average of 2.6 per 1,000 annually in the pre-sulfonamide period to 3.0 per 1,000. Possible reasons for the increased frequency of pneumonia are discussed. There is no evidence that sulfonamide therapy, *per se*, is responsible for the increased prevalence of pneumonia and other factors such as congestion in industrial areas incident to the war effort may be responsible. Since all types of pneumonia were included in the study it is possible that an increase in the number of cases of "atypical" or virus pneumonia may in part be responsible for the observed increase in the frequency of pneumonia.

NOTE: The authors acknowledge with thanks the assistance of Miss Ruth Unverzagt in assembling the statistical data.

Industrial Eye Health Problems*

HEDWIG S. KUHN, M.D.

Hammond, Ind.

IN a war program industry is geared to top capacity. It must of necessity, therefore, reduce waste, not only of time, equipment, machinery and raw materials, but also of man power and skills. It is useless and unfair to ask any employee to improve his work and reduce his mistakes if he is not able to see the work, or does not have the necessary visual skill for his specific job. An understanding of the manifold elements that make for visual skill has until recently been overlooked. The protective measures needed to cut down eye hazards, while understood, have been inadequately applied.

Especially during a period of stress such as the present it is necessary to focus attention on visual conservation in industry. There are two main problems which are of concern to both management and employees.

The first concerns the need for visual *admission* standards. In many industries where visual requirements have been set up, a single arbitrary specification has been used, based only on central visual acuity for distance. Instead, one should recognize the eyes as a binocular unit with multiple functions, each of which has definite bearing upon the individual's ability to meet the demands of a specific job. This, in turn, permits a simple classification of jobs, grouping together those having approximately the same types of visual work and safety requirements. Already there is some basis for such grouping, but

further investigation is needed to develop a placement program that is adequate to fit any and all types of industry. Selection will need to be concerned not only with general aptitudes and physical health, work skills, and craft training, but also with visual aptitudes.

The second problem involves the use of a similar visual testing procedure in conducting a *survey* of employees within a given industry. Here it is important to apply the same yardstick of standards of visual functions, based on the needs of the job, as that used in hiring new applicants. Thus employees already on the pay roll, who fail to meet the visual requirements for their specific job, can be made to qualify for the special visual demands of that job, or can be transferred where necessary.

Industry is already engaged in a five to ten year stretch of intensified activity no matter what the international sceneshifts may be. Perceptual abilities of all kinds are the first essential with which to meet this immense effort. Among these abilities, excellence of visual performance ranks first.

EYE PROTECTION

The question of proper handling of eye injuries is necessarily in the hands of the ophthalmologist consulted. The constantly changing processes in industry mean new uses of gases, fumes, chemicals, glares, and materials whose possible toxic effect on the eye demands persistent study by the ophthalmologist. The engineer too must play his part

* Read before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

by revision of processes to reduce hazards and by developing devices and methods for the control of such hazards. Goggles for protection from flying objects, from gases, from the chemicals (liquid or solid), from light, etc., are constantly being improved. Samples of such personal protective equipment designed for every purpose are displayed at each safety conference and are available to any safety director in either a large or a small plant. Special goggles for women are being developed with reference to the weight of the goggles and the cosmetic aspects. The setting up of a goggles program includes the study of the type of goggle and of the economics involved. An "all out" program which provides goggles for everyone, with industry paying the full bill is, generally speaking, the best. Special economic problems arise in providing goggles which correct refractive errors. Some employers may feel that the employee who needs glasses to see in private life should have a greater share in financing the goggles where the lens prescription is incorporated. Those industrial processes that involve frequent replacement of the lenses or goggles, as in excessive pitting, have other special economic angles. All of these variables can be worked out with fairness both to management and to the employee, where there is good will and a desire to have a fully satisfactory arrangement. Good quality, standard tested merchandise is assumed. Fitting of frames, temple pieces, measurement of interpupillary distance, etc., are essential for ordinary plano goggles as well as corrected-vision protection. An ambulatory repair service has proved excellent in many large plants. And, finally, the proper educational background work and the sharing by labor and management in setting up specific plant methods, makes an eye protection program generally practical and possible.

VISUAL TESTING IN INDUSTRY

On the basis of our recent visual survey of over 16,000 workers in ten or more types of industry, presented in detail to the American Academy of Ophthalmology and Otolaryngology, and an intensive study of the visual requirements of some additional 10,000 workers for specific jobs, we could come to only one conclusion—that to evaluate an individual's ability to do a certain job safely and efficiently as far as his vision is concerned, involves much more than a mere knowledge of his central visual acuity for distance.

Only when he has before him all of these data can the admission examiner decide whether a man is fitted to be a craneman or machinist, or whether a girl can be an efficient inspector or comptometer operator. One of the most striking revelations of this survey was the extraordinary correlation between accuracy and efficiency of work on the one hand, and perfection of visual performance on the other. These relationships show conclusively that much more than visual acuity is involved in the evaluation of "eyes for the job" and that any other criteria are obsolete.

Visual testing falls into three main categories—(a) preemployment, (b) periodic rechecks of special groups, and (c) plant surveys. For the duration of the war especially, there need be few or no rejections of applicants for jobs. However, for this very reason there must be more accurate and practical admission records in order that placement personnel can quickly consider visual safety and visual skill of applicants. More than ever we want to conserve eyes, man power and high production efficiency. In certain dangerous jobs especially dependent on full visual acuity and binocular coordination, periodic rechecks are needed to discover changes in the eyes. For example, crane operators and drivers of

automotive vehicles and machines are as much in need of periodic visual appraisal as are aeroplane pilots, for whom such reappraisals are already accepted practice. There are certain exceedingly important and vital jobs, such as the reading of precision instruments like micrometers and gauges, setting of precision lathes, inspecting or reading of blue prints, where accuracy and production efficiency depend also on the changing human eye. For employees in all of these and many more types of work, rechecks are indicated at stated intervals. Some industries which now have been made a part of the vital war effort have never had any sort of visual testing program. Critical divisions and sections of these plants will profit tremendously by a visual survey geared to meet their individual needs. Probably not until after the war will a visual testing program become possible as an inclusive entity.

The basic visual data industry needs recorded for each employee include:

1. Distant and near central visual acuity without glasses
2. Distant and near central visual acuity with glasses
3. Muscle unbalances (phorias) for distance and near
4. Depth perception
5. Color appreciation levels
6. Near vision test, depending on individual and job

Special emphasis on near vision tests is always indicated where an employee is 40 years and over. But for applicants for all jobs requiring exact visual skills at a working distance within 16 inches there should be added a standardized test for near point at convergence, and near point of accommodation and a refraction for work distance with the lenses prescribed for that specific distance. This statement cannot be overemphasized as industry draws to its ranks more employees in the upper age brackets and more indi-

viduals previously unused to close work. The ordinary street-wear bifocals do not necessarily meet the work needs as related to distance or types of spectacles indicated for occupational use.

The correlation between degree of perfection of visual skills and production level has until very recently been largely overlooked in this country.* Some work had been done in England but a dramatic and brilliant statistical analysis of this and many other hitherto unstudied phases of the problem of visual factors in efficiency was made possible through our research program by the coöperation of the Department of Applied Psychology at Purdue University. This breakdown of survey data into almost a million correlations will be an epoch-making study. This joint effort by industry, psychology, and ophthalmology seeks to validate technics, validate the needs and proposed instrumentation, establish a scientific yet practical interpretation of visual defects from the standpoint of occupational needs, and to lay a solid foundation for the contemplated program of remedial recommendations both before and after hiring. All the work to date points to a direct and consistent relationship between maximum production, maximum accuracy, and the visual perception components.

Medicine may now therefore directly conserve not only the health of an individual's eyes, but can help to increase the production schedules for management and raise the income of the employees. The various rehabilitation problems involved in a war program are becoming more and more important. Among these corrective problems are: training of adult individuals who lack coördination of the eye muscles to develop the needed binocular skills; proper refraction for job distance and

* Tiffin, Joseph, Ph.D. *Industrial Psychology*. Prentice-Hall, 1942, pp. 124-184.

prescription of glasses in relation to that job; detection and care of changes or disease in an employee's eyes as revealed in the periodic testing; equipping each individual so that he is able to meet the visual requirements of his assigned job. Advances and progress in the field of industrial ophthalmology, in eye protection equipment, in the analysis of visual aptitudes, in the classification of jobs as related to visual skills and, especially, the unexpected responsibilities of ocular rehabilitation in a country at war, have been so rapid that constant reference to current scientific literature is indicated.

The contribution of ophthalmology to the war program therefore includes the provision of reliable protection to the eyes of workers, with the aim of maximum production and minimum waste.

Tetanus Toxoid and Its Use for Active Immunization*

D. T. FRASER, M.C., M.B., D.P.H., F.A.P.H.A., D. L. MACLEAN, M.B., D.P.H.,† M.D. ORR., H. C. PLUMMER, PH.D., AND F. O. WISHART, M.D., D.P.H.

Connaught Laboratories, School of Hygiene, University of Toronto, Toronto, Canada

THIS study records the antitoxin response to tetanus toxoid in young adults. The first part of the study deals with the results obtained following two doses of toxoid as compared with three doses of an identical antigen. The second part has to do with the response to three doses of a combined antigen, made up of typhoid, paratyphoid A and B vaccine, suspended in tetanus toxoid.

Preparation of toxoid—In the preparation of the toxoid used in these studies, the following details are relevant. Upon the outbreak of war large quantities of tetanus toxin were prepared in anticipation of the requirements of toxoid for the armed forces. The broth used for this purpose was a veal infusion base with 1.5 per cent Witte's peptone added. With this medium the potency of the toxin obtained varied between 20,000 and 150,000 m.l.d. (guinea pig) per ml. Detoxification was carried out in the usual manner with formalin and storage at 37° C. The comparison of the antitoxin response to two doses and to three doses of antigen was based upon the results obtained with toxoid thus prepared. For convenience

of expression and reference, toxoid made in that manner is designated, Toxoid A. Experience with this toxoid, used under field conditions, showed that reactions of an anaphylactic character were occasionally encountered.¹ In consequence of this, the use of Witte's peptone in the medium for the preparation of toxin was discontinued in the spring of 1940, and hog stomach autolysate plus veal infusion was substituted, Toxoid B. Later, the medium used for the production of toxin was one adopted for the purpose by E. M. Taylor,² the basis of which was half veal infusion and half hog stomach autolysate treated with calcium chloride in order to reduce the iron content to a fixed level. A small amount of nicotinic acid was added, and the pH set at about 7.0. The strain of *Clostridium tetani* used throughout for the production of toxin was obtained in 1929 from the New York State Health Department, and used in these laboratories continuously since that time. Incubation was carried out at between 35° C. and 36° C. for 10 or 11 days. The yield of toxin with this medium has been satisfactory. During a period of 18 months, for example, of 130 lots of toxin made, 72 were between 100,000 to 220,000 m.l.d. per ml. Twenty lots of the 130 had a value of less than 30,000 and were discarded. Toxoid made in this manner with Taylor broth,

* Presented at a Joint Session of the Health Officers, Laboratory, and Epidemiology Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

† Lt. Col., Royal Canadian Army Medical Corps.

Toxoid C, was combined with typhoid, para A and para B vaccine. The broth used for tetanus Toxoid B and tetanus Toxoid C is basically very similar to that used by Ramon for his combined antigen employed for many years in the French armed forces, and without the occurrence of reactions of an anaphylactic character. Similarly no such reactions have been reported following the extensive use of Toxoid B for a period of approximately 1 year, and of Toxoid C for 2 years. The antigenicity of the toxoid was tested either by the method of flocculation, antitoxin response in guinea pigs, or combining power, or a combination of these methods.

PART I

Comparison of the antitoxin response to two and three doses of tetanus toxoid—This experiment was carried out in two groups of volunteers to determine the comparative antitoxin response to an identical antigen, Toxoid A, used in two doses and three doses of 1 ml. given during the same total elapsed time. The intervals shown in Table 1 were approximately 6 weeks be-

For convenience, the results of the titration of the 61 blood samples of the two dose group, and the 54 in the three dose group may be considered as falling into two categories. Thus, in the two dose group, 82 per cent of persons have at least 0.01 unit of antitoxin, in contrast to 92 per cent in the three dose group. Taking 0.1 unit as a basis of comparison, the results in the two groups are more strikingly contrasted; 23 and 68 per cent respectively. On the basis of this study, which was carried out late in 1939, it was felt justified to recommend without hesitation that three doses of toxoid be used in place of two, and given within the elapsed time of 6 weeks. As a matter of fact, since three doses of typhoid para A and para B vaccine were recommended for the armed forces it seemed convenient and logical for administrative purposes to combine tetanus toxoid with the typhoid antigen (T.A.B.T.)* as had been advocated by Ramon, and had been the current practice in the French armed forces since 1936.³ This combined antigen was introduced for use in the Canadian armed forces in the spring of 1941.

† 28 and 11 days respectively between doses

tween the first and second doses in the two dose group, and in the three dose group 1 month between the first and second and 2 weeks between the second and third doses. A blood sample was obtained 70 days after the final dose in each group. The antitoxin titrations of the serum were carried out at various levels, in mice.

Antitoxin response to a recall dose—It was urgent to gain experience of the effectiveness of the recall dose ("dose de rapell," of Ramon) for tetanus toxoid. The coöperation of 20 persons

* 750 million *Bacillus typhosus*, 250 million *B. paratyphosus* A, and 250 million *B. paratyphosus* B, per ml. of tetanus toxoid, containing about 10 Lf per ml.

was obtained (8 in the two dose group, and 12 in the three dose group) to take 0.1 ml. of Toxoid A, 70 days after the last dose had been given. The small secondary stimulus was chosen primarily to determine whether by a small subcutaneous dose one could detect the persons who had become highly sensitive to Witte's peptone toxoid, Toxoid A, through previous inoculations. If no reaction were obtained with this small dose within, say, $\frac{1}{2}$ hour, the full dose could then, if desired, be administered with a greater feeling of safety. In the group of 20 volunteers no evidence of sensitivity was encountered. This is not surprising, considering the small size of the group and the known infrequency of reactions, following Toxoid A preparations. It is obvious that the small dose used in our study weighted the odds against the antigen. If, under these exacting conditions, the response in antitoxin were good, one would perhaps be justified in inferring that a larger dose would not evoke a lesser response and, indeed, probably a better one. That such is the case is borne out later in this study. Because of the urgency of the situation, it was also thought justifiable to shorten the time between the primary series of in-

oculations and the recall dose to 70 days, and to measure the response in antitoxin within 9 days. These factors also tend to weight the odds against the effectiveness of the antigen. Thus by imposing the very exacting and unfavorable conditions under which the antigen was used, the results, if good, could be accepted with some degree of confidence, and serve as a firm basis for formulating recommendations as to the dosage of tetanus toxoid. It will be seen from Table 2 that all but 2 in the three dose group, and 1 in the two dose group, showed an increase in antitoxin within 9 days. Thus, in spite of the limitations imposed upon the antigen by the conditions of the experiment, 85 per cent of 20 persons showed an increase in antitoxin following the small secondary stimulus of 0.1 ml. There is much evidence that the antigen now supplied has much higher antigenic potency, hence the results of this experiment are particularly encouraging. The tetanus toxoid now used is made from toxin pooled to contain 100,000 m.l.d per ml. as contrasted with the early lots of toxin of 40,000 m.l.d. per ml.

The effectiveness of a small stimulus, 70 days after the primary inoculation,

was also explored in a group of 38 persons, 25 in the two dose group and 13 in the three dose group, 1 month after the secondary stimulus of 0.1 ml. Toxoid A. The response after 30 days was essentially the same as after 9 days (Table 2), that is to say, 85 per cent showed an increase within 9 days and 84 per cent an increase within 30 days.

PART II

Response to three doses of T.A.B.T.

—Before the combined antigen, which is officially designated as T.A.B.T., was recommended for use in the armed forces it was urgently required to carry out a trial of the antigen under field conditions. This trial was commenced in July, 1940, on a small group, from 79 of whom we were able to obtain blood samples 8 weeks after the third dose. Three doses of 1 ml. of the combined antigen, T.A.B.T., were given with intervals of 3 weeks between doses. It will be seen from Table 3 that 99

TABLE 3

Units of Tetanus Antitoxin per ml. of Blood Serum, 56 Days After Third Dose of T.A.B.T.

<i>Units Antitoxin per ml. of Serum</i>	<i>Number of Subjects</i>	<i>Per cent of Subjects</i>	
<0.001	1	1.3	} 12.7%
0.02-0.1	9	11.4	
0.1-0.5	54	68.3	} 87.3%
≥0.5	15	19.0	
Total	79	100.0	

per cent of 79 persons had at least 0.02 unit of antitoxin, and 87 per cent had at least 0.1. This is a very satisfactory result and gives one a high degree of confidence in the effectiveness of tetanus toxoid as an antigen. Based chiefly on theoretical evidence, supported by laboratory experiment, 0.01 unit has been suggested by certain workers⁴ as the level required to establish clinical immunity. On this basis,

the fact that 99 per cent of 79 persons had 0.02 unit per ml. of serum leaves little to be desired. However, it should be emphasized, though it is perhaps not surprising, that one individual did not respond with any detectable amount of antitoxin (<0.001 unit).

Although the figures are not large and the conditions for a critical test are wanting, since the identical antigen was not used in the comparative tests, the result of the trial with T.A.B.T., suggests that the combined antigen may be more effective than without the added typhoid element (see MacLean and Holt⁵). It happened that the initial m.l.d. (40,000) of the toxin was the same in each of the particular lots of Toxoid A and Toxoid C used for the results shown in Table 1 and 3. In comparing the two groups, it will be noted that 68 per cent of 54 persons (three dose group) had at least 0.1 unit of antitoxin as contrasted with 87 per cent of 79 persons, following three doses of T.A.B.T. The difference between the results in the two groups, one without, the other with added bacterial vaccine, is of statistical significance. It is, of course, not to be inferred that the initial m.l.d. of the toxin is the sole determining or necessarily the most important factor in the antigenicity of the toxoid made therefrom.

Response to a recall dose of T.A.B.T.

—An opportunity arose to obtain information on the rapidity and degree of antitoxin response to a secondary stimulus using T.A.B.T. 0.5 ml. at approximately 1 year after the primary course of inoculations. The antigen used in the initial course was Toxoid A or Toxoid B (Table 4a), given in two doses, generally at 6 weeks interval, or three doses of T.A.B.T. given at intervals of 3 weeks (Table 4b). This latter antigen was introduced in the Canadian armed forces in the spring of 1941.

It must be emphasized that the groups under investigation are not en-

1st Recall dose given 12-18 months after last dose of primary series of inoculations

Table 4A—Primary inoculation = 2 doses of Toxoid A or B—blood drawn immediately before and 10-14 days after 1st recall dose

Table 4B—Primary inoculation = 3 doses of T.A.B.T.—blood drawn from 10 days to 9 months after 1st recall dose

tirely satisfactory from the point of view of the accuracy of history of primary inoculations. For example, of 105 persons (Table 4a), in 16 instances no data were obtained as to previous history, except that the subjects had been required to have their recall dose. Under the circumstances of the mobility of troops it was impossible to obtain more accurate data. In Table 4a, are shown the results of a group given initially Toxoid A or B, two doses of 1 ml. with an interval of 6 weeks. Of 105 subjects, 92 per cent showed at least 0.1 unit per ml. within 10 to 14 days after the first recall dose of 0.5 ml. of T.A.B.T. Actually 74 per cent of the whole group had more than 1 unit, 15 per cent more than 10 units, and 1 individual, 70 units. As is well established in the response to diphtheria toxoid, the individual variation is very great. It is striking that a small group responded either not at all, or very poorly. Fortunately this is a small group; 3 only showing no response within the limits of the test (<0.001 unit). It may be significant that the 3 persons who showed no measurable

response (<0.001 unit) to the recall dose had similarly no measurable antitoxin at the time the stimulus was given. One of these individuals is recorded as having had only one dose, approximately 2 years prior to the recall dose. Of the remaining 2, 1 had an interval of 2 months between his first and second dose, the other had 11 months between his first and second dose. However, one does not wish to emphasize these anomalies of inoculation as being the underlying cause for the poor response. The histories are not completely reliable and there are other similar anomalies in the group with good response. For example, there are, among the 105 subjects, 10 who are recorded as having had only one dose, but who as a group showed a satisfactory response following the recall dose. Every effort has been made to verify the histories of those who did not respond, and we have no evidence that they did not receive the doses as recorded.

It may be noted that, in general, the higher the level of antitoxin at the time of the secondary stimulus, the greater

the antitoxin response. For example, all those with 0.01 unit of antitoxin or more at the time of the recall dose, had at least 0.1 unit after the recall dose; indeed, the great majority had at least 1 unit. As a matter of fact, of those having <0.01 unit before the recall dose, none showed as much as 10 units after the recall dose, whereas, of those having at least 0.01 or more initially, 15 per cent had 10 or more units.

Table 4b shows the results obtained in a group similar to that shown in Table 4a, except that the initial series of injections was T.A.B.T., and no titrations were made upon the sera previous to the recall dose. The blood samples were not obtained strictly within 2 weeks, as is the case of the subjects of Table 4a—most of them being drawn within 2 months, and 2 at 9 months. It appears that, on the whole, the response to the recall dose following the initial injections of T.A.B.T. is better than that following two doses of Toxoid A or B. Thus 92 per cent of 63 persons had at least 1 unit of antitoxin per ml., in contrast to 74 per cent of 105 subjects of Table 4a. This difference is statistically significant. It should be emphasized that one person failed to respond with any detectable amount of antitoxin. Thus,

in a total of 168 persons (Tables 4a and 4b) 4 (2 per cent), did not respond to the recall dose, and 3 others responded poorly (<0.01 unit). Boyd and MacLennan⁶ have mentioned the possibility of lack of response being overcome by a recall dose of toxoid in referring to the development of tetanus in 5 inoculated men. Our results show that of 21 persons (Table 4a) who had no detectable antitoxin 1 year after the primary injections, 18 responded to a recall dose. It seems clear that the majority of persons, even though they have no detectable antitoxin, do respond to a recall dose, but some do not.

Response to a second recall dose of T.A.B.T.—We were fortunate in being able to obtain blood samples from 31 persons who had had two recall doses of 0.5 ml. of T.A.B.T. at an interval of approximately 1 year. Blood was drawn at the time of the second recall dose and about 10 days later. The results are presented in Table 5a. It is of interest to contrast these results with those shown in Table 4a. In the latter table, 42 (40 per cent) of 105 persons had less than 0.01 unit per ml. of serum before receiving a recall dose, whereas all in Table 5a had at least 0.01 unit before receiving the second recall dose.

TABLES 5A AND 5B

*Units of Tetanus Antitoxin per ml. of Blood Serum After
First or Second Recall Dose of 0.5 ml. T.A.B.T.*

Table 5A Units of Antitoxin 1 Year after 1st Recall Dose	Number of Subjects	Units Antitoxin per ml. Serum after 2nd Recall Dose			
		0.1- <1.0	1.0- <5	5- <10	≥ 10
0.01- <0.05	8	3	5
0.05- <0.1	2	1	1
0.10- <1.0	16	3	11	1	1
1.0- <5.0	5	..	1	2	2
Total	31	7	18	3	3
Table 5B Titration Not Done before 2nd Recall Dose	36	3	13	12	8

Second recall dose given approximately 1 year after 1st recall dose

Table 5A—Blood drawn immediately before and from 10 to 14 days after 2nd recall dose

Table 5B—Blood drawn from 10 days to 17 months after 2nd recall dose

As might be anticipated, the level of antitoxin is, in general, much higher 1 year after the first recall dose than 1 year after the primary series of inoculations. In so far as the response to the second recall dose is concerned, only 1 of the persons in Table 5a had a level of antitoxin below 0.5 unit, whereas 8 per cent of 105 persons (Table 4a) had less than 0.1 unit. Table 5b shows the results of titrations obtained from a group similar to that in Table 5a, except that no blood samples were obtained previous to the recall dose, and that the samples were not obtained strictly within the 2 weeks time. All of these 36 sera showed at least 0.1 unit per ml. Thus, each of the 67 sera comprising Tables 5a and 5b had at least 0.1 unit per ml. after the second annual recall dose.

Although the numbers are not large, it may be of significance that, before the first recall dose was given, 20 per cent of persons shown in Table 4a had less than 0.001 unit per ml., and 20 per cent of persons, in addition, less than 0.01 unit per ml., after a primary series of inoculations 1 year previously. This is in striking contrast to the results presented in Table 5a, in which it is shown that all had at least 0.01 unit 1 year after the first recall dose, that is to say, 2 years after the primary inoculations. There seems thus no doubt that the level of antitoxin is higher a year after the recall dose than a year after the primary series of injections.

In view of these results and based upon the good and prompt response to a small dose of toxoid given 70 days after the primary injections (Table 2), we suggest that the interval between the primary three inoculations of T.A.B.T. and the first recall dose be not less than 3 and not more than 6 months, and the second recall dose be given 1 year later. This does not, of course, preclude the giving of toxoid at the time of the infliction of a wound whenever this

should occur. Modification of this schedule may be made in order that the recall dose coincide as nearly as is practicable with the entry of troops into the combat zone.

In general, it may be assumed that the longer the interval between the primary series of injections and the recall dose the better. However, the shortening of the interval between the primary series and the first recall dose (4th dose) would seem from our study to offer certain distinct advantages. The antitoxin content would reach higher levels sooner, and be longer maintained, and the disturbingly low levels found 1 year after the primary series (Table 4a) would not obtain. Further, the second recall dose which in our studies has been shown to be very effective, could be given 15 to 18 months after the primary series in place of 24 months as is the current practice.

SUMMARY

By the use of a medium of veal infusion and hog stomach autolysate, tetanus toxin of high titer has been obtained. Following the use of toxoid made therefrom no reactions of an anaphylactic character have been reported.

By comparing the effectiveness of an identical tetanus toxoid, given to two groups in the same period, namely 6 weeks, our results show that the response in antitoxin in persons given three doses of tetanus toxoid is better than in persons given two doses.

Represented numerically. 68 per cent of 54 persons in the three dose group had at least 0.1 unit of antitoxin per ml. of serum 70 days after the last dose of tetanus toxoid, as compared with 23 per cent of 61 in the two dose group.

Under conditions which weighted the odds against the antigen, a small (0.1 ml.) secondary stimulus given 10 weeks after the primary series of inoculations caused 85 per cent of 20 persons to show an increase in antitoxin titer within 9 days.

A combined antigen of tetanus toxoid with typhoid vaccine (T.A.B.T.) given in three 1 ml. doses, 3 weeks apart, stimulated the production of at least 0.02 unit of antitoxin in 99 per cent of 79 persons, and at least 0.1 unit in 87 per cent.

Although the conditions for a critical comparison are lacking, since the identical antigen was not used in the two groups compared, the results suggest that tetanus toxoid with the typhoid element added (T.A.B.T.) is more effective than without.

Under field conditions the effectiveness of a recall dose of 0.5 ml. of T.A.B.T. was explored. Of 168 persons, 92 per cent had at least 0.1 unit of antitoxin per ml. of serum following the first recall dose.

In general, the antitoxin response to a recall dose is less in persons with low levels of antitoxin than in persons with relatively higher levels.

In general, the levels of antitoxin are distinctly higher in persons 1 year after a recall dose than 1 year after the primary inoculations.

From 10 days to 17 months after a second recall dose, given 1 year after the first recall dose, all of 67 persons had at least 0.1 unit per ml. of serum.

The recommendation is put forward that the first recall dose of T.A.B.T. (4th dose) be given not less than 3, and not more than 6 months after the primary series of injections. Modification of this schedule may be advisable in order that a recall dose coincide with the entry of troops into the combat zone.

Use of Current Birth Certificates in Planning a Maternal and Child Health Program*

WILLIAM C. WELLING, F.A.P.H.A., MARTHA L. CLIFFORD, M.D., F.A.P.H.A., AND EDWIN T. TRACY

Director, Bureau of Vital Statistics; Director, Bureau of Child Hygiene; and Research Assistant, Bureau of Child Hygiene, Connecticut State Department of Health, Hartford, Conn.

THE birth certificate contains a wide variety of information directly applicable to maternal and child health problems, and therefore can be used to good advantage in planning a maternal and child health program.

We shall discuss the information from the birth certificate according to (A) Data available without machine tabulation; (B) Data available with the use of machine tabulation, according to the following outline:

- A. Data available without machine tabulation
 - 1. Number of births according to residence of mother
 - 2. Number of births according to town of occurrence
- B. Data available by use of machine tabulation
 - 1. Number of births according to hospital where birth occurred
 - 2. Residence of mother according to hospital where birth occurred
 - 3. Blood test according to hospital where birth occurred
 - 4. Occupation of father according to hospital where birth occurred
 - 5. Occupation of mother
 - 6. Length of stay in community according to:
 - a. Time of blood test
 - b. Order of birth

The text of this paper demonstrates how information from the birth certificate can be used in planning such basic maternal and child health services as prenatal care, care at the time of delivery, postpartum care of the mother, and care of the infant.

Connecticut can be described as a compact industrial state of 1,709,242 population according to the 1940 census. The basic unit for the administration of local government and local health work is the town. There are 169 in all, of which Hartford is the largest, with a population of 166,267, and Union the smallest, with a population of 234. There are 24 towns with a population of over 10,000. During the period January 1 to July 1, 1942, there were 15,878 births reported. For this same period there were 1,170 maternity beds in 43 licensed maternity hospitals.

A record of the number of births is kept on a current month to month basis in Connecticut according to the residence of the mother and the place of occurrence. These records are open for inspection and analysis to all bureaus of the State Department of Health as soon as the birth certificate is received and recorded. If the information is summarized every 6 months, trends can be seen in time to plan necessary health services.

* Based on a paper presented at a Joint Session of the Vital Statistics and Maternal and Child Health Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

A. DATA AVAILABLE WITHOUT MACHINE TABULATION

1. An application of the use of the data according to the residence of the mother appears in Figure 1. Here is shown the location of those towns that have experienced a 50 per cent or more increase in resident births during the first 6 months of 1942, compared with the first 6 months of 1940. These towns have been correlated with towns considered to have inadequate nursing service. Nursing service was considered inadequate if, according to the records of the Bureau of Public Health Nursing, there was less than 1 public health nurse per 3,000 population. The director of the Bureau of Public Health Nursing, upon seeing this map, immediately saw areas in which the information could be applied to the educational and promotional public health nursing program.

By a similar treatment of the data on births, the existing and potential problems relating to medical services can be graphically pointed out. At a time when physicians are being withdrawn for military service, maps showing towns with an increased birth rate as well as an increased population due to war industries will be useful in determining which towns require more medical personnel for civilian needs. Persons directing a maternal and child health program will find such information useful in determining need for prenatal clinics, well child conferences, etc.

2. It was stated above that the birth certificates are recorded currently by town of occurrence in Connecticut, and that this information is readily available to establish trends for comparison between local health units, or with the state as a whole.

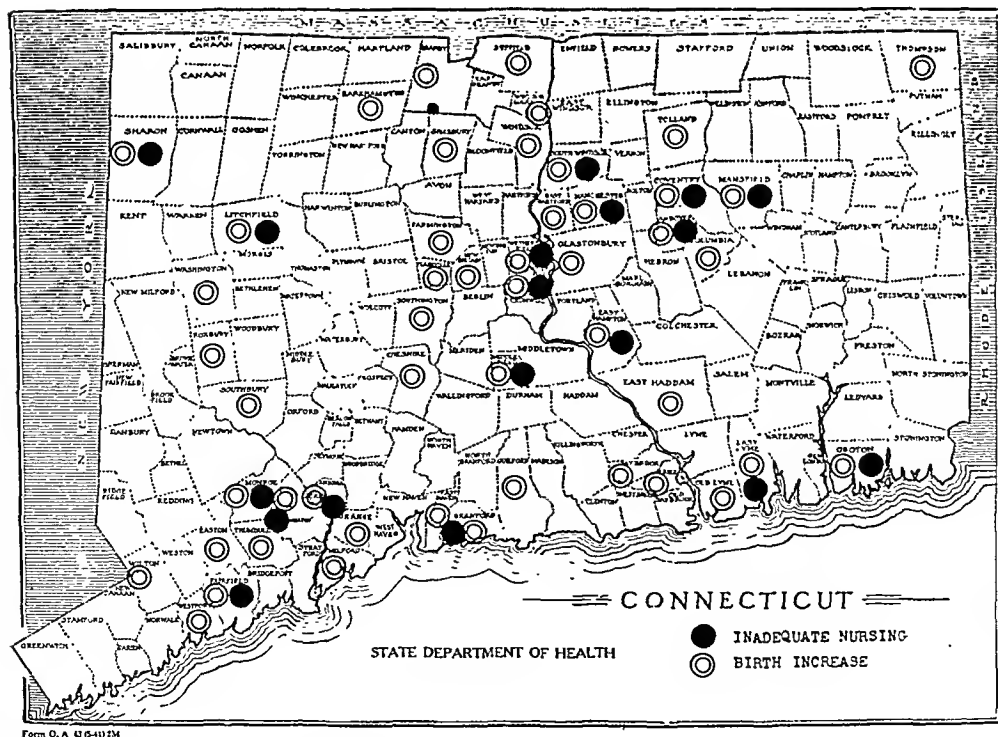

FIGURE 1—Inadequate nursing service in towns having a 50 per cent birth increase between January-June, 1940, and January-June, 1942

B. DATA AVAILABLE BY USE OF MACHINE
TABULATION

1. It will be possible to open a much wider field of investigation by sorting and tabulating the births on a hospital and home delivery basis. When the number of maternity beds for which a hospital is licensed is known, knowledge of the number of births that occurred in a particular hospital makes it a simple task to compute the maximum number of postpartum days which that hospital can carry its maternity patients at an accepted occupancy rate. We have used a 75 per cent occupancy rate for all hospitals and hereafter shall refer to this maximum number of postpartum days that a hospital can carry its patients as a "theoretical maternity stay." The formula for computing the theoretical maternity stay is as follows:

$$\text{Theoretical maternity stay} = \frac{\text{Number licensed beds} \times \text{occupancy rate} \times \text{number survey days}^*}{\text{number births during survey}}$$

* The period of our survey is 6 months, or 180 days.

Table 1 shows a selected group of hospitals demonstrating varying degrees of overcrowding that exist. Hospitals C and D are of nearly the same size and are located in the same city. Hospital C which has a theoretical maternity stay of 9.1 days considers itself overburdened, although there are other hospitals within the state that are carrying a much heavier maternity load. However, in a competitive sense hospital C has to offer its patients a shorter postpartum stay than hospital D whose theoretical maternity stay is 13.5 days. Hospitals B and F are located in the same city, but hospital F with 15 licensed maternity beds and a theoretical maternity stay of 48.2 days is a municipal institution and so is not used for private patients.

Hospital E, which has a theoretical maternity stay of 14.6 days, has been

TABLE 1

*Theoretical Maternity Stay in Certain
Selected Hospitals*

<i>Hospital</i>	<i>Number of Births</i>	<i>Hospital Beds</i>	<i>Theoretical Maternity Stay</i>
A	399	20	6.8
B	1,803	91	6.8
C	656	44	9.1
D	672	67	13.5
E	490	53	14.6
F	42	15	48.2

given a complete federal grant for a maternity building extension. Although this grant was made just prior to the more rigid restrictions on priorities, this hospital was not nearly so overcrowded as were many others in the state. This kind of information should be of value to an agency set up to adjust an equitable distribution of hospital services.

It was interesting to find after computing the theoretical maternity stay for all hospitals that in certain hospitals, where the length of stay before discharging patients was known, the theoretical maternity stays indicated a length of stay *too short* to allow patients to remain as many days postpartum as they were actually remaining. On investigation it was found that *additional* beds were being used for maternity cases.

The average theoretical maternity stay available during the 6 month period for all hospitals in the state was 9.8 days. If we accept a 10-12 day theoretical maternity stay as normal, it would seem that there are nearly ample hospital beds in the state to care for maternity patients at this time. The chief difficulty is in getting the patients to existing facilities.

If we have information on births within a health unit on both a hospital and residence basis, we will be in a position to predict where maternal and child health problems are likely to arise because of increased births. Reference to Table 2 will illustrate this point. Resident births have increased in town M by 52.8 per cent and in town N at

TABLE 2

Theoretical Maternity Stay and Percentage Increase in Resident Births in Selected Towns

Town	Births by Place of Occurrence	Hospital Beds	Theoretical Maternity Stay in Hospitals	Percentage Increase in Resident Births *
M	781	43	7.4 days	52.8
N	389	21	7.3 "	57.4
O	269	22	11.0 "	62.9
P	106	16	20.4 "	42.4
Q	530	38	9.7 "	2.5
R	305	25	11.1 "	2.8

* Increase between January-June, 1940, and January-June, 1942

the rate of 57.4 per cent, and, as might be expected, the theoretical maternity stays of the hospitals within these towns are very low. In towns O and P the birth increases are 62.9 and 42.4 per cent respectively, but there is no apparent overcrowding of the hospitals' maternity facilities as shown by their relatively high theoretical maternity stays, 11.0 and 20.4 days. Still another situation exists in towns Q and R where the increases in resident births are almost nonexistent, 2.5 and 2.8 per cent in the order named, while the theoretical maternity stays are comparatively low. Clearly, if we were informed on either "the increase in births" in a town or the "theoretical maternity stay," but not both, and attempted to predict the other on the basis of the one we know, we might reach an erroneous conclusion.

2. A very useful arrangement of the data will be a cross-tabulation of the births according to the individual health unit where the mother resides and by the hospital where the birth occurred. This tabulation will furnish information on the movement of mothers for de-

livery, where they went to have their babies, and from what localities they came. In practice, if this tabulation is made, all of the information on births thus far described will be available from this one table.

Having knowledge of mothers who were residents of one town but who were delivered in another, it is possible, with the aid of a road map, to find the distance a mother traveled to be delivered. What type of hospital she went to and what hospital she by-passed can be found by inspection. Table 3 shows the distance traveled by 376 mothers who were delivered in hospitals located in town X but whose residence was nearer to another general hospital.

For example, 14 mothers traveled 20-25 miles to be delivered in town X, whereas the nearest general hospital licensed for maternity patients was 5-10 miles from their residences.

There were 3,013 births occurring in hospitals in town X—1,366 were to mothers who were residents of towns other than town X, and of these 376, or 27.5 per cent, traveled farther to be

TABLE 3

Distance Traveled by Mothers to Be Delivered in Town X Compared to Distance to Nearest Hospital

		Distance to Town X					
Distance to Nearest Hospital	Miles	5-10	10-15	15-20	20-25	25 over	Total
	Less than 5	106	44	50	1	15	216
	5-10	75	2	3	14	15	109
	10-15	17	3	4	24
	15-20	9	6	12	27
	Total	181	46	79	24	46	376

delivered in hospitals in town X than if they had gone to their nearest hospital. If the time comes when hospital facilities must be rationed, such information as this will be useful. Also it may be possible to determine from such information the cost of allowing patients to choose their place of delivery.

Information concerning hospital and home deliveries can also be determined. As in other states, the proportion of hospital deliveries has been increasing in Connecticut in recent years. This trend continued in Connecticut during the first 6 months of 1942. In 1940, 90.8; in 1941, 94.0; and for the first 6 months of 1942, 95.8 per cent of the births occurred in hospitals. However, factors such as an increased birth rate and overcrowded hospitals are now rising which may influence this trend. If home deliveries do increase, either in the state as a whole or in some area in the state, it will be advisable to know this so that more attention may be directed toward stimulating home delivery nursing services and enlisting local women's organizations to make obstetrical bundles for physicians' use at home deliveries.

When a hospital's maternity facilities are overtaxed, it will be obliged to limit its admissions to the number for whom safe care can be given. In order to offer care at the time of delivery to as many mothers as possible, the hospital may have to reduce the length of stay of postpartum cases. It is recommended that a public health nurse or other designated worker visit the home of every expectant mother to evaluate the suitability of the home for delivery and for care of the mother after early discharge from the hospital. If such a visit is made by a public health nurse, she can easily guide the mother in making preparations. Either a public health nurse or another designated worker can cooperate with the hospital in its selection of patients for early discharge by reporting her findings of the home conditions.

From information on the birth certificate we know which hospitals are overtaxed and which communities could improve their care for mothers and newborn infants by making investigations of the homes.

3. There is a Connecticut statute which became effective July 1, 1941, that requires each physician giving prenatal care to the pregnant woman in the state to take or cause to be taken a blood test for syphilis within 30 days from the date of the first examination, and to state on the birth certificate whether the test has been made and, if made, the date when such test was made and, if not, the reason why such test was not made.

It is possible to determine from information on the birth certificate how the law is being carried out. It was found that 13,540 of the 15,787 cases studied, or 85.8 per cent, answered the question "Was a blood test made?" while the remaining 2,247, or 14.2 per cent, did not answer the question. Of the 13,540 cases reported on, 12,522, or 92.5 per cent, stated that a blood test actually had been made while in the remaining 1,018, or in 7.5 per cent of the cases, it was specifically stated that no blood test was made. The second part of the blood test question asks "date of test?" This question was answered on 10,691, or 85.4 per cent, of the 12,522 records where it was stated a blood test had been given.

This information is of value to those administering venereal disease programs as well as those concerned with maternal and child health problems. Knowledge of the month that the pregnant women received a blood test is important when evaluating the effect of a venereal disease program while the stipulation in the law that the blood test be given within 30 days of the first examination furnishes a valuable index on the time of the mother's first visit for prenatal care. The distribution of the 10,691 cases that

reported on the date of the blood test according to the time during pregnancy that the test was made follows:

<i>Time blood test made</i>	<i>Number</i>	<i>Per cent</i>
Before fifth month	4,549	42.5
Fifth month to term	5,407	50.6
Same day or after delivery	735	6.9
Total	10,691	100.0

It was interesting to see that the answering of the question on the blood test followed a hospital setup, with certain hospitals reporting nearly completely and others not at all. It is hoped that in the future, in the case of those physicians who have not reported the date of the blood test, a convenient method can be devised of transferring this information from their office records to the hospital records in order that reporting can be complete. We believe this would reduce the number of those not reporting.

4. The birth records may be divided according to the occupation of the father. This information can be used to find an estimate of the number of wives who would be eligible for care under the program for medical care for wives and children of men in military service (except commissioned officers) and to get an estimate of the number of fathers who worked in industries which are predominately engaged in war production. It was found that, for the first 6 months of 1942, out of 15,787 births 272, or 1.7 per cent, were born to wives of service men (except commissioned officers). This figure could be used as a maximum number of wives who might be eligible for care. We were also able to estimate from the data on occupation of father that approximately 50 per cent of the fathers of infants born during this period were engaged in war production industries. In planning for the medical care of these infants through their preschool years some thought should be given to the eco-

nomic status of families now supported temporarily by war industries.

We are aware of a case where a hospital in the state, admittedly overcrowded, was refused a request for materials to build a new wing because it was felt that other hospitals with similar needs were giving service to a larger proportion of families where the wage earner was engaged in vital war production. As we had sorted the question on occupation of father on a hospital basis we were able to test whether this assumption was correct. We found within reasonable certainty that this hospital was exceeded by only one other in the state in so far as the percentage of births to fathers engaged in war production industries was concerned.

It was felt that the mother's choice of hospital for delivery might be influenced by the location of her husband's place of employment. If this were so, we should expect to find, among those mothers who traveled to be delivered, a larger proportion of the wives whose husbands worked in a town going to that town to be delivered than of the wives whose husbands did not work there. As the code on occupation of the father had also been arranged to identify the names of certain selected industrial plants where the fathers worked, it was possible to test this hypothesis. The records of those births where the father was known to be employed in a certain factory were separated according to whether his wife was delivered in the town where he worked (designated town Z). In order to eliminate the residents of town Z and residents of other towns who would be expected to utilize only those hospitals in town Z, we used only those towns where less than 75 per cent of the cases had been delivered in town Z during the survey period. Eighty-three of the 289 mothers whose husbands worked at the factory in town Z, or 28.7 per cent, came to town Z to be

delivered. Using the same towns as a base, it was found that, of the remaining 1,086 births where the husband did not work at the selected industrial plant, 204, or only 18.8 per cent, came to town Z to be delivered. It would seem that there was evidence to support the opinion that the father's place of employment influenced the mother's choice of hospital. It might be well for the public health nurse to inquire into the mother's motive when it is known that she intends to travel farther than necessary to be delivered, especially when the hospital she plans to attend is in a shortage area.

5. The occupation of the mother was tabulated to learn the extent to which pregnant women were working outside the home. Although our experience led us to believe that the reporting on this item made it unreliable to use, it is felt that the question was not clearly defined. The expectant mother may have worked outside the home prior to and during part of her pregnancy but we have reason to believe that she will report her occupation as "housewife" if asked during the latter part of her pregnancy after she has stopped working. We feel that it would assist the person filling out the birth certificate if the question on the mother's occupation were worded: (a) Employed outside the home during pregnancy Yes No; (b) If yes, usual occupation; (c) Industry or business

6. If we know that the population within a health unit is being increased

because families are moving in from other areas, we should be interested in finding out if there is any difference between the old and new residents in respect to the factors associated with the births. Since the birth certificate asks the "length of mother's stay in this community" it was possible to separate the births on this basis. It was necessary to limit the analysis to those births where the residence of the mother was the same as the town where she was delivered. This situation existed because the question on "length of stay" is asked under the block headed "Place of Birth." We feel that this question would have more utility if asked under the block headed "Usual Residence of Mother." Although we have information on "length of stay in community" on only 6,705 of the 15,787 births reported, we feel that any errors that the data may contain are not selective to the birth certificates on which has been reported the length of stay in the community.

Table 4 presents the distribution of the 5,328 births on which was reported the month of gestation at which mothers had a prenatal blood test according to the length of stay in community. The mothers who had been residents of a town for 6 months or less did not have a blood test as soon as mothers in the other classifications. It would seem, however, that the new residents adjusted themselves very quickly to the standard of the older residents in the matter of seeking early prenatal care.

TABLE 4
Time of Blood Test by Length of Mother's Stay in Community

<i>Length of Mother's Stay</i>	<i>Total Reporting No.</i>	<i>Before 5th Month</i>		<i>5th Month to Term</i>		<i>Same Day or After Delivery</i>		<i>No Test Taken</i>	
		<i>No.</i>	<i>%</i>	<i>No.</i>	<i>%</i>	<i>No.</i>	<i>%</i>	<i>No.</i>	<i>%</i>
Under 6 months	244	53	21.7	144	59.0	30	12.3	17	7.0
6-11 months	333	131	39.4	157	47.1	18	5.4	27	8.1
12-23 months	428	175	40.9	196	45.8	27	6.3	30	7.0
24-35 months	236	104	44.0	109	46.2	11	4.7	12	5.1
36 months and over	4,087	1,625	39.9	1,895	46.3	209	5.1	358	8.8
Total	5,328	2,088	39.2	2,501	46.9	295	5.5	444	8.3

Table 5 shows the distribution of 6,674 births on which was reported the order of birth according to the length of the mother's stay in the community. It is apparent that a trend exists toward smaller families in the newer population groups especially in the proportion of mothers having their first baby. It is not certain whether this smaller percentage of first births (births of order I) to residents of less than 6 months reflects a real change. It may be, since these women were pregnant when they moved, that the primiparae were reluctant to leave their old homes before their babies were born.

In addition to the items mentioned above, it is possible to separate the

necticut which receive in the State Bureau of Vital Statistics copies of birth certificates from the local registrars are not in a position to refer cases into the field soon enough to be immediately effective. However, many of our larger cities, as well as health units in many other states where the registrar receives the birth certificate directly, can work out a system which will best serve their own needs according to the facilities which are available. New York City, which has been a pioneer in the use of the birth certificate for case finding in the maternal and child health program, now requires the physician to file a birth certificate within 48 hours after the birth.

TABLE 5

Order of Births according to Length of Mother's Stay in Community

<i>Length of Mother's Stay</i>	<i>Total Reporting No.</i>	<i>Births of Order I</i>		<i>Births of Order II</i>		<i>Births of Order III and Over</i>	
		<i>No.</i>	<i>%</i>	<i>No.</i>	<i>%</i>	<i>No.</i>	<i>%</i>
Under 6 months	302	170	56.4	70	23.2	62	20.5
6-11 months	403	276	68.5	72	17.9	55	13.6
12-23 months	551	351	63.7	100	18.2	100	18.2
24-35 months	306	159	51.9	87	28.4	60	19.6
36 months and over	5,112	2,302	45.0	1,463	28.6	1,347	26.4
Total	6,674	3,258	48.8	1,792	26.9	1,624	24.3

births according to any other information contained on the birth certificate. The factors of age of mother, age of father, legitimacy, past mortality experience of the mother and prematurity are tabulated annually by the Bureau of Vital Statistics but may have added value in the planning of a maternal and child health program if the information is available on a current basis.

The birth certificate furnishes, moreover, a valuable means of locating and selecting cases that need special attention. The value which the birth record may have in selecting individuals for direct service depends upon the speed with which the information can be made available to the medical and nursing field staffs. States like Con-

SUMMARY

In practice the director of maternal and child health would ask the director of vital statistics for guidance in determining what information from the birth certificate could be made available and the form in which it will be most useful. In some vital statistics divisions, it may be a practice to code and punch the information from birth certificates after the end of the registration year rather than currently. In this case it will be possible to secure only a minimum amount of information, but even this will be worth while to the division of maternal and child hygiene. There may be additional items which appear on the birth certificate which formerly were not tabulated, but may be of value,

and now the use of them justifies the past decision to include them on the birth certificate.

The pattern of life in all sections of the country is being disturbed during this wartime period. Redistribution of families with children, overcrowding of housing units, wives and infants of soldiers, and working mothers bring new health problems at a time when public health personnel is needed for work connected with the war. Information which will locate these sore spots is

available on the birth certificate. To be of value it needs to be used currently.

NOTE: In the preparation of this paper, valuable assistance was received from Jacob Yerushalmy, Ph.D., Director, Division of Statistics Research, Children's Bureau, U. S. Department of Labor, who indeed inspired and suggested the study. We should like to thank Mrs. Caroline A. Sheehan, Chief Tabulator, Bureau of Vital Statistics, Connecticut State Department of Health, whose assistance with the tabulation contributed to the completion of the paper.

TRENDS AND FORCES IN PUBLIC HEALTH ADMINISTRATION

NO sensible person would undertake to prophesy the extent and character of public health work during the next ten years. The situation contains too many variables and intangibles to permit a detailed forecast. It seems fairly safe, however, and possibly may be of benefit, to review those factors and pressures which have shaped public health practice in the past. Then, on the assumption that they will continue, one may attempt to guess how they will influence and be influenced by existing and future pressures.

Viewing the past, one must be impressed by the fact that, broadly speaking, two influences have tended to determine the amount and kind of public health work done by the health departments. The first of these has been the extent of scientific knowledge available; and the second, social concepts as manifested in government. The way in which these forces have operated has not been simple, but rather the contrary. For instance, whether in the past or future, mere possession of knowledge as to control of a given disease is not enough. Such knowledge remains only of academic interest unless it can be applied. Its application, in turn, may be inhibited by excessive costs, by diffuseness of the problem to be met, by the fact that control measures would entail restrictions of daily living, or a meticulousness in personal conduct that human beings will not observe. Again, the public health methods available for application of scientific knowledge may be quite clumsy, or the public or officials of government or the medical profession may not be receptive to its application under governmental auspices.

Always these factors have acted and reacted upon one another in any attempt to apply scientific knowledge. The result is that as newer knowledge became available it was applied more here and less there, but nowhere in full force; and although there was always a net gain to the public health, accomplishments fell far short of what was possible.

The rôle of the second element mentioned above, that is, current social philosophy, and its influence on the amount and kind of public health work done, was and is exceedingly complex. It is also very important, for the structure and function of a health department, the type of its administration, and the scope of its health program, must inevitably fluctuate within the framework of the government of which it forms a part. Further, these health activities were and will currently be shaped by the policies of the government's chief executive and cabinet, by its legislative body, to some extent by its courts, and by its economic resources. This applies in all governmental spheres: federal, state, and local. Behind the governments, of course, is public opinion which, though sometimes slow and fumbling, always and inevitably makes itself felt. In relation to health work, public opinion was sometimes crystallized and produced voluntary health organizations long before the influence of this opinion brought action through governmental authorities.

Because government and its contained social philosophy influences health work, it is important to note that all levels of government in the United States are undergoing change. Of significance in this connection is the fact that larger governmental units are becoming more articulate and forceful in imposing benefits and policies upon smaller ones. Federal tends to press upon state and state upon local. This is made effective and painless by the use of subsidies from above downward. Billions of dollars, and even millions, are deep-voiced and persuasive. Another significant change is that federal government is tending strongly toward social legislation containing provisions as to health and medical care.

Summarizing the trend in these principal forces which shape the work of health departments, it may be said that in the field of scientific knowledge, upon which public health work must rest, one finds a broader base than ever before existed, with the promise of much more to come in the near future. Sociologically, one finds a federal government strongly inclined toward legislation and appropriations for social betterment, with an increasing tendency to raise the ceiling on benefits the citizen has a right to expect of government, and somewhat strong-armed as regards *meum et tuum* in federal-state relationships.

It seems inevitable that out of these broadening resources and strong tendencies, unless there is a post-war relapse into rugged individualism, the pattern of public health practice will be shaped more than ever before by federal agencies, that better standards of work and a greater uniformity of procedure will come into play, that more funds will be available, that there will be higher qualifications for public health personnel, with civil service tenure of office which will protect alike the just and the unjust and those who are good and those who are not so good. It seems likely, too, that there will be a lessened sharpness in the dividing line between preventive and curative medicine, that much of medical care will become a function of public health service, that public health organizations will, by nature and resources, be better prepared to apply new knowledge as it becomes available.

Some of those engaged in public health work would welcome these things, including their derivations and implications, with shouts of glee. Others will wonder if the surrender of considerable local initiative will not, in the end, be too high a price to pay. In any event, it seems reasonable to believe that modern public health service will be extended to the uttermost rural hamlet and township, and perhaps even to a few of those cities now sitting upon their ancient and somewhat withered public health laurels.

ARE COUNCIL AND BOARD MEMBERS PEOPLE?

PARENTS appear to be divided into two classes. First, there are those who hope, naively, to carry their youngsters through adolescence without experiencing mental anxiety for, and clashes of will with, their children. Second, there are those who have tried to do this and know it cannot be done.

Parents who expect to avoid disobedience and sowing of wild oats on the part of their children, seem to forget that they themselves, if they are now bearable and effective personalities, gave their parents some disquiet. They overlook, too, the fact that if there is to be no disobedience, no resentment of authority, no venturing into new and perhaps dangerous fields, the new generation would be but a replica of the old. It would be disastrous if this should happen in any large proportion of the young people. For one thing, it would seriously retard progress of race and civilization, for older people and their prototypes tend to develop too great an esteem for precedent, to resent the threat of change. Further, new horizons would remain unexplored, for the old mind is not curious as to what is beyond the hill, provided it is not the poorhouse. What is needed is the commando type who will not only go over the hill, but will acquire the poorhouse and either burn it down or turn it into a night club.

As with parents and families, so it is with business, industries, organizations, and associations. Chronic chairmen, perennial board members, and ubiquitous committeemen tend to assume a parental rôle in organizations and, just as parents cannot concede that a new generation has arisen, so these elder statesmen insist that policies of the past must shape current and future procedures.

It is at least permissible to wonder if these things might not well be taken to heart in professional organizations, such as the American Public Health Association. The Editor has a feeling that old names and old faces, including his own, have too long occupied strategic positions on boards and committees; that not enough thought has been given to the necessity of harvesting the presently maturing crop of epidemiologists, administrators, nurses, engineers, laboratory workers, etc., etc. When we, as a Fellow of the Association, attend a committee meeting, we have a pleasant assurance that we shall meet old friends. At the same time, we experience a dull distress because we know that we shall not find new, or even foolish, enthusiasms, or venturesomeness, and youthful vigor.

If someone wants to campaign for a candidate under forty for the Governing Council, the Executive Board, or Editorship of the JOURNAL, we shall joyously back his man (unless he has served a prison term of more than a year *) against the fifty-and-over field.

* Make it two years.

BOOKS AND REPORTS

Victories of Army Medicine: Scientific Accomplishments of the Medical Department of the United States Army—By Edgar Erskine Hume. Philadelphia: Lippincott, 1943. Price \$3.00. 250 pp.

The Medical Department of the United States must be credited with many notable achievements. Three immediately occur to anyone who knows anything of medical history: the experiments by Beaumont on Alexis St. Martin; the conquest of yellow fever by the committee of which Walter Reed was chairman; and the Army Medical Library with its *Index Catalog* for the great development of which we are indebted to the late John S. Billings. Of these, Dr. William H. Welch regarded the last as "America's greatest gift to medicine." The conquest of yellow fever is rightly considered one of the most beneficent gifts to mankind, and the work of Beaumont was the first really scientific study of digestion, on which life depends.

Not only does Colonel Hume give the record of the U. S. Army, but also some of the history of the Medical Department of the Confederate Army during the Civil War. When the South seceded 3 surgeons and 23 assistant surgeons gave up their commissions in the U. S. Army and went to the defense of their Confederacy. The history of the Confederate Army remains to be written, and the records of the Surgeon General's office were burned at the fall of Richmond, but Colonel Hume mentions several notable achievements. The Confederacy founded and conducted the Chimborazo Hospital at Richmond, Va., which with its 9,000 beds, became the largest military hospital that has ever existed in

America. It was in the charge of Surgeon James B. McCaw, father of General Walter D. McCaw, Chief Surgeon of the A.E.F. in the World War. A notable accomplishment also was the book by Dr. Francis Peyre Porcher who was a skilled bontanist as well as a physician. The book, *Résources of the Southern Fields and Forests*, was written in order to supply the medical deficiencies of the Southern Army since medicines were contraband of war. The Surgeon General of the Confederate Army founded also the Association of Army and Navy Surgeons, the oldest American military association of the country, since the present Association of Military Surgeons was founded only in 1891.

Once again Colonel Hume has put the medical profession of the country in his debt, and has done a notable service in writing this memorial to the great men who have served in our armies. Like all of Colonel Hume's writings, the book is filled with facts of the most interesting character, which any reviewer finds it hard to pass without mention. The book is entirely up to date, including the most recent additions to our medical outfit, such as dentistry, nursing, and veterinary medicine. Aviation medicine and warfare gases are considered. Accounts of the many medical boards are also given, and short sketches of a number of the chiefs of other branches of the Army than the medical are also included. There is a list of all the chiefs of the medical department of the U. S. Army, beginning in 1775 and going to 1939; of the librarians of the great library, the curators of the Army Medical Museum, General Hospitals created before 1940, and those since. There are com-

plete references to the subjects considered. Altogether the book is most valuable and interesting.

It is but natural that Colonel Hume should wish to give all possible credit to the Army, but we must take exception to his attributing to General Sternberg the discovery of the pneumococcus (page 187). There is no doubt that he saw it but so did Pasteur the same year, though neither suspected its relation to pneumonia. Acting Assistant Surgeon Aristides Agramonte, who was a member of the Yellow Fever Board, is said to have been Professor at the University of Havana until his death. This may be correct, but he was also at the time of his death Professor of Tropical Medicine at Louisiana State University. The library of the Medical School of the institution is named "The Agramonte Memorial Library."

The book is beautifully printed and profusely illustrated. One color plate shows Colonel J. S. Billings in uniform, over which is the gown of Doctor of Civil Laws of Oxford University. Reproductions of many title pages of notable publications abound. It is a "must" book for all medical libraries and contains information which educated people generally should have.

MAZÏCK P. RAVENEL

Sanitary Inspector's Manual—By Ben Freedman. New Orleans: Louisiana State Department of Health, 1943. 360 pp.

In this manual an effort has been made to bring together information useful to the Louisiana sanitarian. It is put together in such a way as to be adaptable to field use, has numerous illustrations and a good index. Generous quotations are made from standard documents to avoid repetition. The entire environmental sanitation field is covered with due respect, of course, to the laws and regulations of the state in which the manual is to be used. This

manual should be popular with Louisiana sanitarians for it contains the material for use in formulating answers to most of the problems such workers will face. To be most useful, however, this manual will have to be kept abreast of the times. ARTHUR P. MILLER

Synopsis of Diseases of the Skin—By Richard L. Sutton, M.D., and Richard L. Sutton, Jr., M.D. St. Louis: Mosby, 1942. 413 ill., 481 pp. Price, \$5.50.

The authors have succeeded admirably in their objective, which is to present in compact form a general view of skin diseases. It is obvious that effort has been made to eliminate unnecessary discussion in the interest of simplicity and practicality.

The section on syphilis discusses in a few lines massive dose arsenotherapy in early syphilis. This important subject, which has been hailed as the greatest advance in the treatment of syphilis since the discovery of salvarsan, deserves more space, especially since massive dose therapy is being adopted in many centers in this country, as well as abroad. It is regretted that the word *metarsen* is employed as a synonym for mapharsen. The original non-proprietary designation for this compound was arsenoxide; more recently, and particularly since other manufacturers in this country are preparing it, the term phenarsine oxide hydrochloride has been adopted. The introduction of this strange new term (unknown even to the manufacturing concern which makes mapharsen) will only serve to confuse the reader.

The inclusion of excerpts from original contributions, for example, Shelmire on plant dermatitis, Cole on cardiovascular syphilis, O'Leary on neurosyphilis, and Moore on syphilitic optic atrophy, enhances the value and authority of the volume.

Public health workers may find that

the section on leprosy gives too optimistic a picture of the effects of chaulmoogra oil. McCoy recently stated: "My own observations have led me to the conclusion that the oil and its derivatives are of little or no curative value, and that the unpleasant side effects probably outweigh any advantage to the patient that might possibly accrue from their use."

This book is highly recommended as an up-to-date comprehensive presentation of cutaneous diseases. The reader is constantly amazed at the mass of information contained in a text of 481 pages. Of this volume it may truly be said "multum in parvo."

THEODORE ROSENTHAL

The National Nutrition—By Morris Fishbein, M.D. Indianapolis: Bobbs-Merrill, 1942. 192 pp. Price, \$1.75.

This little book is presumably addressed to laymen as it includes material previously published in *The Saturday Evening Post*, *Red Book Magazine* and *Hygeia*. It seems well suited to the purpose, as it is readable, even amusing in parts, and more than reasonably accurate. The author touches very briefly on many difficult subjects. His object seems to be to draw attention to significant facts which illustrate a moral, rather than to cover the subject, and with this in the case of such a book, one can find no fault. However, it is not in any sense the type of book which seeks to present a particular point of view. The intelligent layman who reads it will be interested, amused, and moderately instructed.

FRANK G. BOUDREAU

China's Health Problems—By Szeming Sze. Chinese Medical Association, Washington, D. C., 1943. 60 pp.

This is the second edition of a volume first published in May, 1942, which sets forth in succinct form an up-to-date

review of China's health problems, including sections on health education, medical education, state medicine, civilian medical relief, the Army medical services, and other subjects. An excellent appendix gives briefly the present status of governmental and voluntary health agencies in China. The author, who is General Secretary of the Chinese Medical Association and Editor of the *Chinese Medical Journal*, is now in the United States.

REGINALD M. ATWATER

Serology in Syphilis Control: Principles in Sensitivity and Specificity—By Reuben L. Kahn, M.S., B.Sc. Baltimore: Williams & Wilkins, 1942. 206 pp. Price, \$3.00.

The importance of this monograph is well bespoken by a single figure: the 16,520,591 serological tests for syphilis performed in this country in 1941. The author has essayed to discuss the implications of variations in serologic specificity and sensitivity to the problem of syphilis control. He has neatly avoided the usual pitfall of the serologist: the tendency to enlarge upon the fascinating details of technic, and has so kept his text within the scope of most of us. The discussions of sensitivity, specificity, supersensitive tests, quantitative serologic reactions, the side effects of mass blood testing programs in the general population and in industry are worth the time of every health officer and venereal disease control officer. A series of papers presented by industrial physicians and venereal disease control officers at a conference called by the author to discuss his verification test are of less importance but are not without interest.

The central thesis of this essay is the importance of specificity in a serological test. When the vast number of routine examinations of serum are considered the number of people affected by a fluctuation of only 1 per cent in the

specificity of a serologic test is rather startling. The 99 per cent specificity which has been considered satisfactory and which seems admirable in comparison with other diagnostic tests may be too loose a criterion.

The plaguing possibility that we diagnose and treat as syphilitic a group of persons whose sera react as do syphilitic sera, but who are not actually infected with the disease, is raised again by the author's discussion. Perhaps we should not assume that every person with a definitely positive serologic reaction has syphilis because almost every syphilitic has a positive serologic reaction. The author seems to proffer his interesting verification test as a partial solution to the problem of detection of biologic false positive reactions. But the interpretation of this test is based upon another assumption: that the reaction which may be detected in the normal sera of various animals is due to the same factor which makes for the false positive reaction in human sera. It would have been interesting to hear more of the proportion of presumably false positive reactions in which the verification test was of assistance in interpretation. But since this test is not susceptible to routine application because of the time and special skill required for its performance, we must continue to regard a definitely positive reaction of a standard test, confirmed by a second examination as sufficient evidence for a diagnosis of syphilis when other diseases tending to produce serologic reactions can be ruled out.

The author reiterates the now familiar plea for a standardization of the sensitivity level of sero-diagnostic tests. It is suggested that such a measure need not, as is often maintained, inhibit the development of new serologic tests or prevent the improvement of those we now have, for the performance of experimental tests which need not be reported could certainly continue. In-

deed, a standardized test could be a criterion of the newer tests. No solution to the major obstacle to such a standardization is suggested: the loss in sensitivity which would result in some laboratories from fixation of the sensitivity level at the average of the least sensitive test considered acceptable.

Serology in Syphilis Control is not a reference text but a thoughtful "Quo Vadis" which is well worth the attention of health officers, laboratory directors, and venereal disease control officers.

JAMES H. LADE

Practical Survey of Chemistry and Metabolism of the Skin—By Morris Markowitz. Philadelphia: Blakiston, 1942. 196 pp. Price, \$3.50.

The book is divided into four parts. The first part goes into the chemistry of the skin itself, giving information not usually found in textbooks on dermatology. Abstracts from the writings on the subject are given and the diseases in which there are deficiencies or excesses of each of the chemical constituents of the skin are named.

The second part of the book deals with hematology and gives the blood abnormalities associated with or diagnostic of various skin diseases.

The third part is on blood chemistry and gives the diseases in which there are changes in the blood nitrogen, blood cholesterol. A special chapter is devoted to histamine and its relation to allergic dermatoses. The chapter devoted to photosensitization and porphyrins is of especial interest.

The fourth part describes the vitamins and gives the diseases in which there is a deficiency of the various vitamins and the skin diseases in which their administration is indicated. It also lists the diseases which may be caused by the excessive intake of some of the vitamins.

Abstracts of the literature make up most of the book. Since many of the

quoted statements in the book are unsubstantiated, it would have been desirable to have the author express his own views on the matter.

An extensive bibliography is appended to each chapter.

LOUIS SCHWARTZ

A Family of Thirty Million—By L. I. Dublin, Ph.D. *New York: Metropolitan Life Insurance Company, 1943. 496 pp.*

Thirty million policy holders of the Metropolitan own nearly \$27,000,000,000 of life insurance. And there is probably no person in the United States who does not enjoy some measure of its protection. What began as a small business in the turbid days following the Civil War has grown to be an American institution. During its early struggles the company seized the opportunity of underwriting the insurance of a sizable society of working people and this experience opened for it the unexplored field of industrial insurance. Concern for the wage earner led to an intelligent desire to better his social conditions. Later, the "ordinary" business was revitalized, largely by bringing 800 field agents and their families to this country from England, but that did not divert the company from its course of studying and meeting the needs of the common man.

A fortuitous meeting of Haley Fiske, President, and Lee K. Frankel, marked the beginning of its systematized welfare program and another happy contact of Dr. Frankel with Lillian D. Wald led to the company's interest in public health nursing. Steadily the welfare program advanced; benevolence and business prospered side by side.

JOURNAL readers familiar with the company's generous participation in public health enterprises will appreciate not only the compact description of the welfare services but also the clear exposition of the principles of life insur-

ance, its business and social implications, and the brief sketches (and excellent portraits) of the guiding spirits. If the tone is at times a bit laudatory this is compensated by the wealth of statistical and factual data. The book memorializes the company's 75th anniversary; its appearance at this time, when understanding of social security is so essential, is most opportune.

H. E. KLEINSCHMIDT

The March of Medicine. *The New York Academy of Medicine Lectures to the Laity, 1942. New York: Columbia University Press, 1943. 217 pp. Price, \$2.50.*

The only excuse I have for writing this review is that I was asked to do it, and that since the lectures were given for the laity, presumably a layman will be able to interpret them for the laity.

Three of the lectures are on well known topics: Tuberculosis, By James Alexander Miller; The History of the B-Vitamins, by Norman Jolliffe; and The Newer Knowledge of Nutrition, by A. J. Carlson. The other three are more abstruse: The Brain and the Mind, by Tracy Jackson Putnam, which is delightful; The Freudian Epoch, by A. A. Brill, which is very informative; and Genius, Giftedness, and Growth, by Arnold Gesell, which goes into flights well above the mentality of the average reader.

There are many statements in each of these lectures which the reviewer would like to comment upon and bring to our readers, but from the standpoint of practicability and interest, we must devote most of our attention to the lecture by Dr. Carlson, which is a criticism of the vast amount of guff which is being poured out to the public through every agency that can be conceived of. Dr. Carlson brings to his subject an exact knowledge, a love of truth, and a devastating wit. He spares no one in his criticisms, which are in every case

authoritatively documented. Concerning the vitamin craze, he quotes from R. R. Williams and R. J. Williams, both of whom, in spite of their excellent work, have made statements and drawn conclusions which border on the chimerical. To go higher up—at least officially—he touches up Mr. McNutt and Surgeon General Thomas Parran, both of whom have made wild statements which do not seem to be supported by facts. Mr. McNutt makes one statement “with the usual lay testimonials which from any other layman would be labeled quackery”; namely, that a trucking company had reduced its night accident rate by giving each driver a bag of carrots before each trip. Most of the statements by Dr. Parran and Mr. McNutt seem to be based upon a series of surveys conducted by the Bureau of Home Economics of the Department of Agriculture assisted by the Department of Labor. They covered only 4,000 urban and 2,000 rural families. The field investigators, some on WPA, depended entirely on the statements of the people questioned. There was no physical or medical examination, determination of body weights, but on the basis of this report the country has rung with statements that at least a third of our population is deficient in nutrition—a statement not borne out by many known facts. Then we have the report of the Subcommittee on Medical Nutrition of the National Research Council which seems to contradict itself, in spite of its imposing origin.

One must read this paper to appreciate its value as well as its keenness. It seems a fashion, led by some in high places as mentioned, to paint the picture as black as possible. In his concluding plea for greater scientific understanding as to human food needs for optimum health, Dr. Carlson demands that we “cleanse our present food and nutrition science of all fads, of all commercial and political propaganda; and

move it from the ivory tower down to comprehension and appreciation of the common man.”

We wish that Dr. Carlson's paper could have a very much wider circulation than this volume will give it. We surely need something to counteract the deluge of radio and other stuff concerning the vitamins from which we are suffering, and it is evident that this information should be given to many who occupy high places, both official and educational.

MAZÛCK P. RAVENEL

Essentials of Industrial Health—
By C. O. Sappington, M.D., Dr.P.H.
Philadelphia: Lippincott, 1943. 626 pp. Price, \$6.50.

This book according to the author represents the application of preventive medicine and public health to industry following closely a recently proposed course for the undergraduate medical student. A wide range of topics is covered in three parts carrying the following titles: Industrial Health Administration, Industrial Hygiene and Toxicology, and Industrial Medicine and Traumatic Surgery. The opening chapter discusses the origin and later development of industrial health throughout the world, and serves to give the reader a fairly complete historical account of the development of this important phase of preventive medicine and hygiene.

In discussing occupational morbidity and mortality in Chapter 2 the author stresses the fact that since true occupational disabilities are a very small part of the whole burden of sickness, the major problem of lost time in industry lies in factors which produce disability common to the general population and outside of industry.

Chapter 3 discusses the distribution of industrial health services beginning with definitions of the scope and objectives of industrial health and includ-

ing estimates of the costs of industrial health service, and the economic and other benefits to be derived therefrom. Reasons why management should be interested in the health of the workers are well stated.

Chapter 4 classifies industrial physicians according to the amount of time spent in rendering services to industrial establishments.

In Chapter 5, which discusses the medical department, it is evident that the author has had the opportunity of obtaining information at first hand. Various aspects regarding quarters are well presented and illustrated with good photographs. In general, the facilities shown are the ideal rather than the average. Little mention is made of "retooling" obsolete medical facilities. Much attention is given to physical examinations of workers. There is a separate section on the special health problems of small plants.

Part II begins with a chapter on industrial health exposures. Included are a series of classifications of dusts, vapors, gases, and skin irritants. Postural strains are briefly treated. More than half of the chapter is devoted to a reproduction of the section in U. S. Division of Labor Standards *Bulletin No. 41* entitled, List of Hazards, Symptoms, Occupations Exposed and Methods of Prevention; the section Alphabetical List of Hazardous Occupations, is not reproduced. Reference is made to safe concentration codes.

In Chapters 7 and 8 the author gives the present-day methods employed in making an industrial hygiene survey of a plant, and the technics involved in determining occupational exposures to hazardous materials and conditions in the working environment. Although it is obviously impossible in a book of this scope to present all the necessary technical details, the author does give sufficient information and references so that the reader will be at least apprised

of the type of work involved in the plant survey and in the matter of plant sanitation and hygiene.

Under personal hygiene for workers is included information regarding toilets and washrooms, fatigue control, nutrition, housing, recreation, and mental hygiene.

In Chapter 10 the author indicates that the industrial physician is in reality the public health officer in industry and therefore should coöperate with all the official health agencies in his community. Subjects presented include the control of tuberculosis, venereal diseases, communicable diseases, and industrial wastes. There is also a brief discussion of health and safety codes and regulations.

Chapter 11 deals with the worker and the job. From the viewpoint of the worker, consideration is given physical and mental fitness, aptitude and psychologic tests, medicine and personnel relations, and women in industry. Under job requirements is included a discussion of length of work week, hours of work, rest pauses, and environmental factors.

One chapter each is devoted to industrial accidents, occupational diseases and non-occupational disabilities. Statistics are given which indicate the extent of some of these problems. The discussion covers broad aspects of morbidity with little attention to clinical features.

The final chapter treats workmen's compensation and rehabilitation under the three sub-headings of administrative methods, medical relations and regulations, and insurance practice.

There are extensive appendices, a list of references, an index of proper names, and a subject index.

J. G. TOWNSEND

The Health Status of N. Y. A. Youth—A Nation-wide Survey of Youth on the Out-of-School Work

Programs of the National Youth Administration. *Federal Security Agency, U. S. Gov. Ptg. Office, Washington, D. C., 1943. 77 pp.*

This report confirms the findings of previous studies of physical fitness of American youth. It is based upon 146,567 complete physical examinations of 71,096 males and 75,471 females between the ages of 16 and 24 years. These young men and women were employed, or seeking employment, on out-of-school work projects of the National Youth Administration. The report states that "the examinations of the present study included classification of each youth on the basis of employa-

bility as determined by health status. The classifying was done by the examining physician according to agreed standards." (p. 31)

The most frequent defect was untreated dental caries, 84 out of every 100 examined needing attention. About 19 per cent of the youth examined needed correction of eye defects and tonsillectomies.

This exhaustive study concludes that nine-tenths of the low income group of youths examined needed medical and dental care and that one-third of them were unfit for certain kinds of productive work on account of health defects.

RICHARD A. BOLT

BOOKS RECEIVED

ALLERGY. By Erich Urbach. New York: Grune & Stratton, 1943. 1100 pp. Price \$12.00.

THE PRINCIPLES AND PRACTICE OF INDUSTRIAL MEDICINE. Fred J. Wampler, Editor. Baltimore: Williams & Wilkins, 1943. 579 pp. Price, \$6.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Have You Given Your Life-Saving Plasma?—From five to nine times as many wounded men are being saved in this war as in the last. Plasma, surgery, and sulfonamides—in that order—are the great lifesavers. Shout this from the housetops: and practise what you preach in the matter of blood donations.

ANON. The Decreased Death Rate in the Army from Wounds. *Science*. 97, 2529:10 (June 18), 1943.

Utopia, Inc.—Briefly presented are the main features of the "Americanized Beveridge plan" which propose to increase present social security coverage in old age and survivor's insurance benefits, disability payments, unemployment insurance, maternity benefits, and medical and hospital services, for 15 million more workers, their wives and children.

ANON. The Wagner-Murray-Dingell Social Security Plan. *J.A.M.A.* 122, 9:609 (June 26), 1943.

Chest X-rays Plus Allowances—Despite wartime difficulties the British Ministry of Health proposes to intensify tuberculosis prevention by extending mass miniature radiography and by granting allowances to persons undergoing treatment. Isn't it about time that we, in this wealthy country, also consider the second feature as a means of getting people to undergo care while there is still hope of successful treatment?

ANON. The Anti-Tuberculosis Campaign. *J. Roy. Inst. Pub. Health & Hyg.* 6, 6:131 (June), 1943.

Gonorrhea Is Still Much Too Prevalent—Last words in the fields of

gonorrhea prophylaxis, diagnosis, treatment, control of patients, criteria of cure, and case finding by a distinguished committee.

ANON. The Management of Gonorrhea in General Practice. *Ven. Dis. Inform.* 24, 5:127 (May), 1943.

Hard Workers Please Note—Medical students voluntarily subsisting upon a diet chiefly deficient in the vitamin B complex (but on a diet such as a third of all Americans subsist on)—developed irritability, easy fatigability, lack of pep, anorexia and increased leg pain during work periods, but at no time did they develop objective physical signs of B deficiency. All the changes returned to normal when a yeast concentrate was added to the diet.

BARBORKA, C. J., *et al.* Relationship between Vitamin B Complex Intake and Work Output in Trained Subjects. *J.A.M.A.* 122, 11:717 (July 10), 1943.

More Comfort for Confinees—Another of the several recent articles on continuous caudal anesthesia is called to your attention chiefly to remind you that many researchers are engaged in perfecting the method. Already more than a thousand births have been reported—the very great majority with relief to the mother, and all without effect upon the baby. Begins to look like the real article.

BLOCK, N., and ROTSTEIN, M. Continuous Drip Caudal Anesthesia in Obstetrics. *J.A.M.A.* 122, 9:582 (June 26), 1943.

Neglected Schick Test—Only a quarter of the previously immunized children were still Schick-positive by the time they reached a hospital for contagious diseases. (They were ad-

mitted for other conditions than diphtheria.) Of 88 children admitted with diphtheria, a third had been immunized but not checked previously. Schick tests should be done after routine immunizations, reasonably concludes the writer.

BULLOWA, J. G. M., and SCANNEL, M. The Efficiency of Inadequate-Antidiphtheria Immunization. J.A.M.A. 122, 9:595 (June 26), 1943.

In Preparation for Polio—During 1942 the incidence of poliomyelitis was relatively low. The states reporting largest numbers of cases were Illinois, New York, California, New Jersey, and Texas. Commenting upon the epidemiologic aspects of the disease, the writer deems it remarkable that, for all the time and effort spent upon the disease, so little new information has been produced. One can improve very little upon Frost's epidemiological discussion published in 1913, he points out.

DAUER, C. C. Poliomyelitis in the United States in 1942 and a Summary of Its Prevalence from 1933 to 1942 Inclusive. Pub. Health Rep. 58, 25:937 (June 18), 1943.

Publican Ideas of Sanitation—Health officers who have in their own communities taverns in which beer is dispensed in improperly sanitized glasses will read with feeling the trials of the British health officer (of Leicester) who found 55 instances in 273 "pubs"—of beer glasses being rinsed in cold water, *or in no water at all*. Several publicans were letting the "swipes" (overflow from glasses) drain back into the barrel.

MACDONALD, E. K., and YATES, J. Notes on Some Matters Connected with Beer Drinking. Pub. Health. 56, 9:106 (June), 1943.

Paper-of-the-Month—Inspiring report upon the United Nations' Conference on Food and Agriculture by one who took part in the deliberations: this state paper is on your "must" reading list, so you'll find no nubbin of

news here to help you guess what it's all about.

PARRAN, T. A Blueprint for the Conquest of Hunger. Pub. Health Rep. 58, 24:893 (June 11), 1943.

Practical Venereal Disease Control—Three dozen centers where venereally infected patients are given modern, intensified treatment, something useful to do, and an allowance for doing it: that, it would seem, is a prodigious step forward in stopping the spread of syphilis and gonorrhea. (Incidentally forty-one centers are "contemplated.")

PEARCE, D. Rapid Treatment Centers. Am. J. Nurs. 43, 7:658 (July), 1943.

Promise of Things To Come—Both bacteria and viruses apparently remain suspended in the air for considerable periods of time and in a viable state. Promising methods for the control of air-borne infections are being studied in an army hospital by a special commission on cross-infections.

ROBERTSON, O. H. Air-Borne Infections. Science. 97, 2527:495 (June 4), 1943.

Every Tumor Is an Induced Tumor—This scholarly discussion of the causes of cancer, especially the viruses, is not easy reading but you will be well repaid for your effort even though you probably will not know the exact meaning of half the technical terms (which you probably will not look up for you will promptly forget the definitions). Just the study of the table of relationships of neoplastic viruses and carcinogens to tumors will prove illuminating. If you do that much, you'll read the rest.

ROUS, P. The Nearer Causes of Cancer. J.A.M.A. 122, 9:573 (June 26), 1943.

Prevents as Well as Heals—Sulfaguanidine proved effective in stopping the spread of dysentery.

SCOTT, J. C. Prophylactic Use of Sulfaguanidine. J.A.M.A. 122, 9:588 (June 26), 1943.

What Army Blood Tests Reveal

—Consider these five pithy commentaries. Syphilis is essentially a disease of Negroes. Our white population enjoys a syphilis rate that compares favorably with any country in the world (including the Scandinavian). Among white men syphilis is a disease of the social outcast. Some health workers tend to gloss over the high prevalence of syphilis among Negroes in north and south, city and country. The sooner we recognize the true situation and get busy doing something about it, the better will be the nation's health.

SMILLIE, W. G. Syphilis in the United States Primarily a Negro Problem. J.A.M.A. 122, 6:365 (June 5), 1943.

Best We Have To Offer—Seven suggested don'ts and do's for parents, should poliomyelitis appear in epidemic form this fall.

STIMSON, P. M. Prevention of Infantile Poliomyelitis. J.A.M.A. 122, 11:764 (July 10), 1943.

"So David Prevailed over the Philistine, with a Sling"—In 46 state, county or city health departments 300 professional and clerical employees comprise the task-force set out to solve the whole nation's industrial hygiene problems that cause the loss of 500 million man days of labor. To mop up the flood of the 10 billions of dollars that sickness costs, just a few dollars over a million are being spent annually. What the valiant 46 units are attempting to do is reported upon.

TRASKO, V. M. Activities of State and Local Industrial Hygiene Services in a War Year. Pub. Health Rep. 58, 24:904 (June 11), 1943.

Sulfa Drug Stops Scarlet Fever—

In the face of a scarlet fever outbreak in a naval station, sulfadiazine effectively stopped the spread and reduced the number of daily sick calls due to other respiratory complaints.

WATSON, R. F., *et al.* Sulfadiazine Prophylaxis in an Epidemic of Scarlet Fever. J.A.M.A. 122, 11:730 (July 10), 1943.

- William M. Friedman, Jr., 45 West Mohawk St., Buffalo 2, N. Y., Jr. Sanitary Engineer, State Dept. of Health
- Elmo G. Liddle, C.E., 16880 Fielding, Detroit 19, Mich., Jr. Sanitary Engineer, City Dept. of Buildings and Safety Engineering
- Dwight F. Metzler, 1362 Greenleaf Ave., Chicago, Ill., Asst. Sanitary Engineer (R), U. S. Public Health Service
- Evan Wright, Kansas Board of Health, Statehouse, Topeka, Kan., Director, Food and Drug Div.

Industrial Hygiene Section

- Robert H. Avery, M.S., Michigan Dept. of Health, Lansing 4, Mich., Industrial Hygiene Engineer
- H. Gardner Bourne, Jr., 1584 Washington St., E., Charleston, W. Va., Acting Director, Bur. of Industrial Hygiene, State Health Dept.
- Frank R. Ferlaine, M.D., 115 E. 61st St., New York, N. Y., Physician in Industrial Medicine, American Telephone and Telegraph Co.
- Anna M. Fillmore, M.P.H., 262 Madison Ave., New York, N. Y., Industrial Nursing Consultant, Henry Street Visiting Nurse Service
- Mary E. Ingoldsby, 1584 Washington St., E., Charleston, W. Va., Industrial Nursing Consultant, State Dept. of Health
- Willis F. Kraemer, M.D., 4200 E. Ninth Ave., Denver 7, Colo., Asst. Director, Div. of Industrial Hygiene, Univ. of Colorado Dept. of Medicine
- Ruth Y. Little, B.S., in N., 366 Playa del Norte, LaJolla, Calif., Industrial Nurse, Consolidated Vultee Aircraft Corp.
- Wayne L. Ritter, M.D., 1046 Whitworth, Jackson, Miss., Assoc. Director, Div. of Industrial Hygiene, State Board of Health
- Harry E. Seifert, M.S., National Institute of Health, Div. of Industrial Hygiene, Bethesda, Md., Sanitary Engineer (R), U. S. Public Health Service

Food and Nutrition Section

- Jana W. Jones, 420 Sixth Ave., N., Nashville, Tenn., Nutritionist, State Dept. of Public Health
- Frances N. Shoun, M.S., 400 W. Hill Ave., Knoxville, Tenn., Staff Nutritionist, State Dept. of Public Health

Maternal and Child Health Section

- Margaret M. Livingston, 410 N. Newstead, St. Louis, Mo., Exec. Director, Planned Parenthood Assn.
- Franco Mortara, M.D., M.P.H., 341 E. 25th St., Dept. of Prev. Med., New York Univ., New York, N. Y., Research Associate
- Ruth A. Parmelee, M.D., M.P.H., c/o A.B.C.F.M., 14 Beacon St., Boston, Mass., Director of Maternal and Child Health, American Board of Commissioners for Foreign Missions
- J. M. Tremblay, M.D., D.P.H., 72 King St., Sorel, P. Quebec, Canada, Medical Officer of Health

Public Health Education Section

- Ruby Bergsvik, 208 Masonic Bldg., Salem, Ore., Exec. Secretary, Marion County Public Health Assn.
- Ann E. Elliot, Richmond County Health Dept., Rockingham, N. C., Public Health Educator
- Elvena F. Fletcher, 2 Byron St., Boston, Mass., Public Health Education Worker, Div. of Adult Hygiene, State Dept. of Public Health
- Frances M. Goodwin, P. O. Box 1703, Boise, Ida., Exec. Secretary, Idaho Anti-Tuberculosis Assn.
- Laurence B. Hall, 133-135 S. 36th St., Philadelphia, Pa., Scientific Assistant, Div. of Venereal Disease Control, U. S. Public Health Service
- Madge E. K. Holderman, R.N., Box 402, Palm Springs, Calif., Riverside County Public Health Nurse
- Laura F. Houpt, 2408 Natchez Ave., Cleveland, Ohio, Staff Nurse, Cleveland Div. of Health
- Charles W. MacMillan, M.D., 4 Duryea Rd., Upper Montclair, N. J., Practising Physician
- Lillian A. Phelps, Peter Bent Hotel, Boston, Mass., Student, Harvard Univ.
- Mrs. Jessie L. Robertson, M.A., 1409 W. Dallas Ave., Houston, Tex., Health Education Director, Houston Anti-Tuberculosis Assn.

Public Health Nursing Section

- Beatrice H. Ditto, 1227 Western Ave.,

Topeka, Kan., Director, Bureau of Nursing, State Dept. of Health

- Evelyn R. Hannon, R.N.R.D.H., 909 National Reserve Bldg., Topeka, Kan., Asst. to Director, Div. of Dental Hygiene, State Board of Health
- Everil E. Harris, Box 173, Caribou, Me., Distr. Supervising Nurse, State Bureau of Health
- Grace M. Lawrence, R.N., 219 Commonwealth Ave., Chestnut Hill, Mass., Supervisor of Public Health Nursing, Newton Health Dept.
- Bessie K. Littman, R.N., P. O. Box 360, San Luis Obispo, Calif., Supervising Nurse, San Luis Obispo County Health Dept.
- Susie M. Rice, R.N., Mountain City, Tenn., Jr. Public Health Nurse, State Dept. of Public Health

Epidemiology Section

- Lieut. Ernest W. Ekermeier, M.C., 458 West College Ave., Tallahassee, Fla., Epidemiologist, U. S. Naval Reserve
- Lieut. Edward R. Garvin, M.C., 1609 Gilbert Rd., Toledo, Ohio, Epidemiologist, U. S. Navy
- Ella T. Robeson, M.D., 34 South St., Middletown, N. Y., Apprentice Epidemiologist, State Dept. of Health
- Robert L. Yeager, M.D., Summit Park Sanatorium, Pomona, N. Y., Medical Director

School Health Section

- Helen M. Edge, 3517 Main St., Kansas City, Mo., Director, Social Service Div., City Health Dept.
- Hilda Ratner, M.D., 31-31 54th St., Woodside, L. I., N. Y., Supervisor of School Physicians, New York City Health Dept.

Unaffiliated

- Gloria H. Cheplin, Yale School of Medicine, Dept. of Public Health, New Haven, Conn., Student
- Thomas L. Hagan, D.D.S., 1307 Pere Marquette Bldg., New Orleans, La., Dental Surgeon, U. S. Public Health Service Dist. No. 4
- Edward K. Steinkopff, M.D., 1537 W. Jackson St., Springfield, Ill., Chief, Div. of Tuberculosis Control, State Dept. of Public Health
- D. Bruce Wilson, M.D., D.P.H., 5 Riverside Crescent, Toronto, Ontario, Canada, Field Staff Member, International Health Division, Rockefeller Foundation

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place at the Wartime Conference.

Health Officers Section

- Franklyn B. Amos, M.D., M.S.P.H., Assistant Director of Local Health Administration, State Department of Health, Albany, N. Y.
 Daniel Bergsma, M.D., Chief, Bureau of Venereal Disease Control, State Dept. of Health, Trenton, N. J. (Major, M.C., U.S.A.)
 Charles A. Kientz, Jr., Health Officer, North Arlington, N. J.
 Edward R. Krumbiegel, M.D., Commissioner of Health, Milwaukee, Wis.
 Carl N. Neupert, M.D., M.S.P.H., State Health Officer, Madison, Wis.
 William M. Smith, M.D., M.P.H., Assistant District Health Officer, State Health Dept., Albany, N. Y. (Capt., M.C., U.S.A.)
 Mary Steichen, M.D., M.S.P.H., Consultant in Public Health Practice, American Public Health Assn., New York, N. Y.
 Wilmier M. Talbert, M.D., M.S.P.H., District Health Superintendent, State Dept. of Public Health, Decatur, Ill. (Lt. Comdr., U.S.N.R.)
 Alexander Witkow, M.D., M.P.H., Director, Dickinson County Health Dept., Iron Mountain, Mich.

Laboratory Section

- G. D. W. Cameron, M.D., D.P.H., Chief, Laboratory of Hygiene, Dominion Dept. of Health, Ottawa, Ont.
 Orren D. Chapman, M.D., Director of Laboratory, Department of Health, Syracuse, N. Y.
 Ward H. Cook, M.D., Director, Bureau of Laboratories, Dept. of Health, Yonkers, N. Y.
 Gordon E. Davis, Sc.D., Senior Bacteriologist, U. S. Public Health Service, Hamilton, Mont. (Capt., Sn.C., A.U.S.)
 William J. Deadman, M.B., City Bacteriologist, City Health Dept., Hamilton, Ont.
 Claude E. Dolman, M.B., D.P.H., Director, Division of Laboratories, Provincial Board of Health, Vancouver, B. C.
 George F. Forster, Ph.D., Assistant Chief, Division of Laboratories, State Dept. of Health, Chicago, Ill.
 R. J. Gibbons, M.D., D.P.H., Assistant Chief, Laboratory of Hygiene, Dominion Dept. of Health, Ottawa, Ont.
 Bettylee Hampil, Sc.D., Head of Virus Dept., Medical Research Division, Sharp & Dohme, Inc., Philadelphia, Pa.

- Margaret W. Higginbotham, Sc.D., Bacteriologist and Serologist, State Dept. of Health, Minneapolis, Minn.
 Cyril K. Johns, Ph.D., Associate Bacteriologist, Division of Bacteriology and Dairy Research, Dominion Dept. of Agriculture, Ottawa, Ont.
 Col. Dwight M. Kuhns, M.C., Commanding Officer, Fourth Service Command Laboratory, Fort McPherson, Ga.
 Edith Kuhns, B.S., Director, Hygienic Laboratory, State Board of Health, Helena, Mont.
 Donald J. Mackenzie, M.D., C.M., Director of Laboratories, Provincial Department of Public Health, Halifax, N. S.
 J. Howard Mueller, Ph.D., Professor of Bacteriology and Immunology, Harvard Medical School, Boston, Mass.
 Ruth M. Myers, M.S., Associate Bacteriologist, State Department of Health, Baltimore, Md.
 Nathan Nagle, A.B., Bacteriologist-in-charge, Chicago Branch Laboratory, State Dept. of Health, Chicago, Ill.
 Elizabeth I. Petran, Ph.D., Senior Bacteriologist, State Dept. of Health, Baltimore, Md.
 Percy M. Phelps, Dr.P.H., Sanitary Bacteriologist, Bureau of Laboratories, Western Michigan Division, State Dept. of Health, Grand Rapids, Mich.
 Norman J. Pyle, V.M.D., Assistant Director, Veterinary Division, Lederle Laboratories, Inc., Pearl River, N. Y. (Major, U.S.A.)
 Clara Raven, M.D., Pathologist and Director of Laboratory, Seranton State Hospital, Seranton, Pa. (Capt., M.C., A.U.S.)
 James D. Reid, Sc.D., Associate Professor, Dept. of Bacteriology, and Supervisor of Bacteriology Laboratories-Hospitals, Medical College of Virginia, Richmond, Va.
 Morris F. Shaffer, Ph.D., Senior Bacteriologist, Massachusetts Antitoxin and Vaccine Laboratory, Jamaica Plain, Mass.
 Major Edgar J. Staff, Sn.C., A.U.S., Officer in Charge, Dept. of Bacteriology, 1st Service Command Laboratory, Jamaica Plain, Mass.
 William A. Starin, Ph.D., Professor of Bacteriology, Ohio State University, Columbus, Ohio
 Lyon P. Streat, Ph.D., D.D.S., Bacteriologist-in-charge, Ayerst, McKenna & Harrison, Ltd., Montreal, Que.
 Charles A. Stuart, Ph.D., Associate Professor,

- Arnold Laboratory, Brown University, Providence, R. I.
- Earl J. Sunkes, D.P.H., Assistant Director of Laboratories, State Dept. of Public Health, Atlanta, Ga.
- William H. Swartzendruber, B.A., Coördinating Bacteriologist, State Department of Public Health, Springfield, Ill.
- Anna I. van Saun, Director, Division of Laboratories, Board of Health, Paterson, N. J.
- Harriette D. Vera, Ph.D., Bacteriologist, Baltimore Biological Laboratory, Baltimore, Md.
- Kenneth M. Wheeler, Ph.D., Research Microbiologist, State Health Dept., Hartford, Conn.
- Lieut. Edwin O. Wicks, A.U.S., Chief, Venereal Disease Section, Fourth Service Command Laboratory, Ft. McPherson, Ga.
- Arthur W. Wright, M.D., Professor of Pathology and Bacteriology, Albany Medical College, and Pathologist and Bacteriologist-in-Chief, Albany Hospital, Albany, N. Y.

Vital Statistics Section

- John W. Fertig, Ph.D., Professor of Biostatistics, DeLamar Institute of Public Health, Columbia University, New York, N. Y.

Engineering Section

- Gerald E. Arnold, C.E., Sanitary Engineer (R), U. S. Public Health Service, San Francisco, Calif.
- Leonard M. Board, C.E., Director of Sanitation Division, St. Louis County Health Dept., Clayton, Mo.
- Herbert M. Bosch, M.P.H., Public Health Engineer, State Dept. of Health, Minneapolis, Minn. (Major, Sn.C., U.S.A.)
- J. Matt Carr, M.S., Sanitary Engineer, State Dept. of Health, Linden, Tex. (Capt., Sn.C., U.S.A.)
- Lloyd K. Clark, S.B., Director, Division of Sanitary Engineering, State Health Dept., Bismarck, N. D. (Major, Sn.C., U.S.A.)
- Charles M. Davidson, B.S.C.E., Sanitary Engineer, Louisville and Jefferson County Health Dept., Louisville, Ky.
- Samuel M. Ellsworth, B.S., Consulting Engineer, and Lecturer, Harvard Graduate School of Engineering, Boston, Mass.
- Herbert B. Foote, C.E., Director, Division of Water and Sewage, State Board of Health, Helena, Mont.
- Harold B. Gotaas, M.S.C.E., Sc.D., Chief of Engineering Section, Division of Health and Sanitation, Office of Coordinator of Inter-American Affairs, Washington, D. C. (Major, Sn.C.)

- Carl D. Gross, M.S., Principal Sanitary Engineer, State Health Department, Springfield, Ill.
- Herbert H. Hasson, B.S., Engineering Director, W. K. Kellogg Foundation, Battle Creek, Mich.
- Chauncey A. Hyatt, Consultant on Swimming Pool Sanitation, State Dept. of Public Health, Chicago, Ill.
- James M. Jarrett, B.S.C.E., P.A. Sanitary Engineer (R), U. S. Public Health Service, Norfolk, Va.
- Francis W. Kittrell, M.S., Associate Sanitary Engineer, Tennessee Valley Authority, Florence, Ala.
- Clarence W. Klassen, B.S.C.E., Chief Sanitary Engineer, State Dept. of Public Health, Springfield, Ill.
- William H. Larkin, C.E., Senior Sanitary Engineer, State Dept. of Health, New York, N. Y.
- Maurice LeBosquet, Jr., M.S., Senior Public Health Engineer, Office of Stream Sanitation, U. S. Public Health Service, Cincinnati, Ohio
- David B. Lee, M.S.S.E., Chief Sanitary Engineer, State Health Dept., Jacksonville, Fla. (Capt., Sn.C., U.S.A.)
- John A. Logan, D.Sc., Chief Engineer, Russell & Axon, St. Louis, Mo.
- Alan C. Love, M.S.S.E., Sanitary Engineer, McLennan County Health Unit, Waco, Tex.
- Franz J. Maier, B.S.C.E., P. A. Sanitary Engineer, U. S. Public Health Service, New York, N. Y.
- Milton M. Miller, M.S., Milk Specialist, U. S. Public Health Service, Washington, D. C.
- Emanuel H. Pearl, M.S.E., Assistant Public Health Engineer, Ohio River Pollution Survey, U. S. Public Health Service, Washington, D. C. (Lieut., Corps of Engineers, U.S.A.)
- Major Harley M. Riley, Sn.C., U.S.A., Assistant Chief, Sanitation Branch, Medical Division, Fort Bragg, N. C.
- Charles L. Senn, B.S.C.E., Director, Sanitation Section, City Health Dept., Los Angeles, Calif.
- L. Glen Shields, M.S., Associate Sanitary Engineer, Dept. of Buildings and Safety, Detroit, Mich.
- Chester A. Smith, B.S.C.E., Associate Engineer, Burns & McDonnell Engineering Co., Kansas City, Mo.
- W. Brewster Snow, M.S., Acting Associate Professor of Sanitary Engineering, School of Public Health, University of North Carolina, Chapel Hill, N. C.
- Frank M. Stead, M.S., Industrial Hygiene Engineer, Los Angeles County Health Dept., Los Angeles, Calif.

James H. Stepiens, M.S., Senior Sanitary Engineer, State Board of Health, Columbia, S. C.

Dick C. Thompson, B.E., Sanitary Engineer, Davidson County Health Dept., Nashville, Tenn.

Clarence J. Velz, C.E., Water Consultant, Region No. 2, National Resources Planning Board, New York, N. Y.

W. Wallace White, C.P.H., Director, Division of Public Health Engineering, State Health Dept., Reno, Nev.

Ben L. Williamson, M.S., Assistant Engineer, State Health Dept., Des Moines, Iowa

Joseph A. Willman, M.S., Public Health Engineer, Muscogee County Health Dept., Columbus, Ga.

Lewis A. Young, M.S., Associate Chief Engineer, Division of Health and Sanitation, Office of Coordinator of Inter-American Affairs, Bogota, Colombia (Capt., Sn.C., A.U.S.)

Industrial Hygiene Section

Joseph C. Aub, M.D., Physician, Massachusetts General Hospital and Professor in Research Medicine, Harvard Medical School, Boston, Mass.

Heinrich Brieger, M.D., Teacher of Public Health and Preventive Medicine, Hahnemann Medical College, Philadelphia, Pa.

Hugh P. Brinton, Ph.D., Statistician, U. S. Public Health Service, Washington, D. C.

John F. Cadden, M.D., M.P.H., Industrial Physician, American Viscose Corp., Roanoke, Va.

Robert H. Flinn, M.D., Surgeon, U. S. Public Health Service, Safety & Security Branch, Office of Chief of Ordnance, War Department, Chicago, Ill.

William G. Fredrick, Sc.D., Assistant Industrial Hygienist and Chief Chemist, Bureau of Industrial Hygiene, Department of Health, Detroit, Mich.

Lydia G. Giberson, M.D., C.M., Industrial Psychiatrist, Metropolitan Life Insurance Company, New York, N. Y.

Lyman D. Heacock, D.D.S., M.P.H., Dental Consultant, Division of Industrial Hygiene, U. S. Public Health Service, Bethesda, Md.

Lemuel C. McGee, M.D., Ph.D., Medical Director, Hercules Powder Co., Wilmington, Del.

Stuart F. Meek, M.D., Assistant Medical Director in charge of Industrial Hygiene, Chrysler Corp., Detroit, Mich.

A. Victor Nasatir, M.D., M.S.P.H., Director of Industrial Hygiene, City Health Dept., Los Angeles, Calif. (Capt., M.C., A.U.S.)

Frank A. Patty, B.S., Director of Industrial

Hygiene, Fidelity & Casualty Co. of New York, New York, N. Y.

O. A. Sander, M.D., In Private Practice in Industrial Field, Milwaukee, Wis.

Alfred N. Setterlind, M.S., Chief Chemist, Division of Industrial Hygiene, State Dept. of Public Health, Chicago, Ill.

Joseph Shilen, M.D., Director, Bureau of Industrial Hygiene, State Department of Health, Harrisburg, Pa.

Emil A. Steiner, M.D., M.P.H., Industrial Toxicologist, Haskell Laboratory of Industrial Toxicology, Du Pont Experimental Station, Wilmington, Del.

James H. Sterner, M.D., Director, Laboratory of Industrial Medicine, Eastman Kodak Co., Rochester, N. Y.

Major Leon H. Warren, M.C., U.S.A., Assistant, Research Coördinating Branch, Plans Division, Office of the Surgeon General, War Department, Washington, D. C.

John J. Wittmer, M.D., Director, Medical and Personnel Departments, Consolidated Edison Company of New York, Inc., New York, N. Y.

McIver Woody, M.D., Head of Medical Dept., Standard Oil Company of New Jersey, New York, N. Y.

Food and Nutrition Section

C. Olin Ball, Ph.D., Technical Director, Owens-Illinois Can Co., Toledo, Ohio

Adelia M. Beeuwkes, M.S., Instructor in Nutrition, University of Michigan, Ann Arbor, Mich.

Florence H. Case, B.S., Nutrition Consultant, State Dept. of Health, Providence, R. I.

Ruth C. Clouse, Ph.D., Chairman, Dept. of Home Economics and Professor of Nutrition, Illinois Institute of Technology, Chicago, Ill.

James E. Fuller, Ph.D., Research Professor of Bacteriology, Massachusetts State College and Experiment Station, Amherst, Mass.

Robert S. Harris, Ph.D., Director, Nutritional Biochemistry Laboratories, Massachusetts Institute of Technology, Cambridge, Mass.

Raymond Hertwig, B.S., Scientific Consultant, The Borden Co., New York, N. Y.

Bertha Holman, Nutritionist, East Harlem Dental and Nutrition Service, Community Service Society, New York, N. Y.

Bernice Hopper, M.S., Principal Nutritionist, State Dept. of Public Health, Nashville, Tenn.

Helen A. Hunscher, Ph.D., Professor and Head, Home Economics Dept., Western Reserve University, Cleveland, Ohio

Ruth M. Kahn, M.S., Chief of Food Clinic,

Washington University Clinic, St. Louis, Mo.

Emanuel Kaplan, Sc.D., Chief, Division of Chemistry, City Health Dept., Baltimore, Md.

Milton L. Laing, M.S., Chief Chemist, Armour & Co., Chicago, Ill.

Louis Lang, M.A., Chief Chemist, National Sugar Refining Co., Long Island City, N. Y.

Ethel A. Martin, M.S., Director of Nutrition Service, National Dairy Council, and Lecturer in Home Economics, University of Chicago, Chicago, Ill.

Roe E. Remington, Ph.D., Professor of Nutrition, Medical College of South Carolina, Charleston, S. C.

Grace H. Sanders, M.S., Director, Division of Health Education, Knoxville-Knox County Health Dept., Knoxville, Tenn.

Jane Sedgwick, B.S., Nutrition Consultant, Bureau of Maternal and Child Health, State Dept. of Public Health, San Francisco, Calif.

Helen R. Stacey, M.A., Specialist in Nutrition, Children's Bureau, Washington, D. C.

Maternal and Child Health Section

William L. Hughes, Ph.D., Acting Chairman, Dept. of Health, Physical Education and Recreation, Teachers College, Columbia University, New York, N. Y.

Betty Huse, M.D., Regional Medical Consultant, Children's Bureau, Washington, D. C.

Emory W. Morris, D.D.S., General Director and Treasurer, W. K. Kellogg Foundation, Battle Creek, Mich.

Ruth J. Raattama, M.D., M.P.H., Director of Maternal and Child Health and Crippled Children, State Department of Health, Boise, Idaho

William M. Schmidt, M.D., Regional Medical Consultant, Children's Bureau, Washington, D. C.

Susan P. Souther, M.D., M.P.H., Chief, Division of Child Hygiene, State Dept. of Health, Columbus, Ohio

Public Health Education Section

C. K. Chu, M.D., Dr.P.H., Director, National Institute of Health, Chungking, China

John E. Farrell, B.A., Executive Secretary, Rhode Island Medical Society, Providence, R. I.

Fay M. Hemphill, M.S.P.H., Health Education Specialist, U. S. Public Health Service, Bethesda, Md.

Rae E. Kauffer, B.S., Assistant Health Education Consultant, U. S. Public Health Service, Washington, D. C.

Alice H. Miller, C.P.H., Associate Health Education Consultant, U. S. Public Health Service, Washington, D. C.

Eunice N. Tyler, C.P.H., Associate Health Education Consultant, U. S. Public Health Service, Washington, D. C.

Epidemiology Section

Nicholas P. Cosco, M.D., Health Officer, Middletown, N. Y.

Herman C. Mason, Ph.D., Associate Professor, Dept. of Bacteriology and Immunology, University of North Carolina, Chapel Hill, N. C.

Unaffiliated

Oswald N. Andersen, M.D., Director, School of Health and Professor of Hygiene, Stanford University, Calif.

Kenneth A. Easlick, D.D.S., Associate Professor, School of Dentistry and School of Public Health, University of Michigan, Ann Arbor, Mich.

Lester A. Gerlach, D.D.S., Dental Director, Health Dept., Milwaukee, Wis.

Allen O. Gruebbel, D.D.S., M.P.H., Director, Dental Division, State Board of Health, Jefferson City, Mo.

Albert D. Kaiser, M.D., Consulting Pediatrician, State Department of Health, and Associate Professor of Pediatrics, University of Rochester Medical School, Rochester, N. Y.

George A. Nevitt, D.D.S., M.S.P.H., P. A. Dental Surgeon (R), U. S. Public Health Service, New York, N. Y.

Walter J. Pelton, D.D.S., M.S.P.H., P. A. Dental Surgeon, U. S. Public Health Service, Washington, D. C.

C. Morley Sellery, M.D., Director, Health Service Section, Los Angeles City Schools, Los Angeles, Calif.

Col. James S. Simmons, M.C., Chief, Preventive Medicine Division, Office of the Surgeon General, U. S. Army, Washington, D. C.

Clifford R. Taylor, D.D.S., M.S.P.H., Assistant Director, Bureau of Public Health Dentistry, State Dept. of Health, Lansing, Mich.

DECEASED MEMBERS

ALICE G. BRYANT, M.D., Boston, Mass., Elected Member 1921, Elected Fellow 1923, Engineering Section

JOHN W. ELDER, M.D., Albuquerque, N. M., Elected Member 1940, Health Officers Section

HARRY B. MELLER, Pittsburgh, Pa., Elected Member 1930, Engineering Section

FRANK C. RAINIER, Whittier, Calif., Elected Member 1940, Laboratory Section

**Preliminary Program of the Scientific Sessions of
the Wartime Public Health Conference and the
72nd Annual Business Meeting of the American
Public Health Association, and Meetings of
Related Organizations**

New York, N. Y.

October 11, 12, 13, and 14, 1943

HOTEL PENNSYLVANIA

THE Annual Meeting Program Committee offers a preview of the content of scientific sessions planned in connection with the Wartime Conference and the 72nd Annual Business Meeting in New York, N. Y. In many instances, sessions are complete. In others, places are purposely left open for important matters which may develop before October. Inaccuracies and omissions are to be expected, and it is hoped they will be excused. The professional affiliations and addresses of speakers are not given, but a complete index to participants will be published in the final program, which will be distributed to all delegates at the Registration Desk, Hotel Pennsylvania. Registration headquarters will be opened at 9:30 A.M. on Monday, October 11.

MONDAY MEETINGS

**AMERICAN PUBLIC HEALTH ASSOCIATION
GOVERNING COUNCIL**

2:30 P.M. First Meeting—Parlor 2.

AMERICAN SCHOOL HEALTH ASSOCIATION

2:30 P.M. First General Session—Salle Moderne.

Presiding: CLAIR E. TURNER, DR.P.H., President.

TODAY'S PROBLEMS IN SCHOOL HEALTH EXAMINATIONS

Panel Leader: HAROLD H. MITCHELL, M.D.

Panel:

ARTHUR R. TURNER, M.D.
C. MORLEY SELLERY, M.D.
WILLIAM E. AYLING, M.D.
GEORGE M. WHEATLEY, M.D.

MONDAY MEETINGS (Cont.)

AMERICAN SCHOOL HEALTH (Cont.)

8:30 P.M. *Second General Session—Salle Moderne.*

Presiding: CLAIR E. TURNER, DR.P.H., *President.*

Report of the Massachusetts Vision Test Study. LURA OAK, PH.D.

Dental Caries Control in School Children. FRANCES KRASNOW, PH.D.

Discussion. WILSON G. SMILLIE, M.D., and E. C. McBEATH, D.D.S.

Citations for Distinguished Service.

AMERICAN SOCIAL HYGIENE ASSOCIATION

8:30 P.M. *Roof Garden.*

CANCER SYMPOSIUM COMMITTEE

Presiding: THOMAS J. DUFFIELD.

SYMPOSIUM ON CANCER CONTROL

10:00 A.M. *Georgian Room.*

EPIDEMIOLOGY

Round Table Discussion

Cancer Research

Epidemiology

Reporting of Cancer Cases in New
York State

Symposium Participants

CLARENCE C. LITTLE, Sc.D.

THOMAS J. DUFFIELD

MORTON L. LEVIN, M.D.

12:30 P.M. *Luncheon Meeting, Hotel McAlpin.*

ADMINISTRATION

State and Federal Cancer Program

County Cancer Program

JAMES W. HAWKINS, M.D.

J. LOUIS NEFF

Round Table Discussion

Symposium Participants

2:30 P.M. *Georgian Room.*

SERVICE TO CANCER PATIENTS—CLINICS, HOSPITALS, ETC.

Round Table Discussion

The State-wide Cancer Record Reg-
istry in Connecticut

Results of Treatment

The Needs of the Terminal Cancer
Patients in Massachusetts

Symposium Participants

ELEANOR J. MACDONALD

HAYES MARTIN, M.D.

HILDA LARROCCA

MONDAY MEETINGS (Cont.)

CANCER SYMPOSIUM COMMITTEE (Cont.)

8:00 P.M. Georgian Room.

CANCER EDUCATION

Round Table Discussion

Education in Cancer
 Evaluation of Educational Program
 in Massachusetts
 The Educational Program of the
 American Society for the Con-
 trol of Cancer

Symposium Participants

CLAIR E. TURNER, DR.P.H.
 HERBERT L. LOMBARD, M.D., MIL-
 NRED TULLY, and EVELYN POTTER
 HERMAN C. PITTS, M.D.

Symposium Participants

MILLARD KNOWLTON, M.D.
 CHARLES L. LARKIN, M.D.
 W. J. MURPHY, M.D.
 RAYMOND V. BROKAW, M.D.
 EDMUND ZIMMERER, M.D.
 HERBERT R. KOBES, M.D.
 MORTIMER WARREN, M.D.

CHANNING C. SIMMONS, M.D.
 FRANK L. RECTOR, M.D.
 LAUREN V. ACKERMAN, M.D.
 GEORGE C. WILKINS, M.D.
 LOUIS C. KRESS, M.D.
 MRS. LEA M. FARRELL
 GEORGE S. T. PEEPLES, M.D.
 CLARENCE F. BALL, M.D.

CONFERENCE OF STATE AND PROVINCIAL PUBLIC
HEALTH LABORATORY DIRECTORS

9:30 A.M. Conference Room 2.

2:30 P.M. Conference Room 2.

CONFERENCE OF STATE SANITARY ENGINEERS

9:30 A.M. Parlor 1.

2:30 P.M. Parlor 1.

CONFERENCE OF TEACHERS OF PREVENTIVE
MEDICINE

11:00 A.M. Parlor 2.

2:30 P.M. Keystone Room.

INTER-AMERICAN CONFERENCE ON HEALTH
EDUCATION

9:30 A.M. Parlor B.

2:30 P.M. Parlor B.

SESSIONS FROM TUESDAY, OCTOBER 12, TO THURSDAY, OCTOBER 14, INCLUSIVE .

TUESDAY, 9:30 A.M.

HEALTH OFFICERS

First Session—Ball Room

Presiding: MALCOLM R. BOW, M.D., *Chairman.*

Section Business.

Present Status of Knowledge Concerning Etiology of Cancer. CORNELIUS P. RHOADS, M.D.

The Epidemiology of Cancer—From the Viewpoint of the Health Officer. MORTON L. LEVIN, M.D.

Results in Breast Cancer Therapy Applied to Control Programs. JAMES W. HAWKINS, M.D.

Primary Atypical Pneumonia. JOHN H. DINGLE, M.D.

LABORATORY

First Session—Roof Garden

Presiding: PEARL L. KENDRICK, Sc.D., *Chairman.*

Section Business.

Report of the Coördinating Committee on Standard Methods. *Chairman,* LIEUTENANT COLONEL A. PARKER HITCHENS, M.C.

Report of the Standard Methods Committee on Diagnostic Procedures and Reagents. *Chairman,* WILLIAM D. STOVALL, M.D.

Report of the Standard Methods Committee on Virus and Rickettsial Diseases. *Chairman,* THOMAS FRANCIS, JR., M.D.

Report of the Standard Methods Committee on Examination of Water and Sewage. *Chairman,* WALTER L. MALLMANN, Ph.D.

Report of the Standard Methods Committee on Examination of Milk and Milk Products. *Chairman,* ROBERT S. BREED, Ph.D.

Report of the Standard Methods Committee on Biology of the Laboratory Animal. *Chairman,* BRIGADIER GENERAL RAYMOND A. KELSER.

Report of the Standard Methods Committee for Frozen Desserts and Ingredients. *Chairman,* FRIEND LEE MICKLE, Sc.D.

Report of the Standard Methods Committee on Biological Products. *Acting Chairman,* HAROLD W. LYALL, Ph.D.

Report of the Standard Methods Committee for the Examination of Shellfish. *Chairman,* JAMES GIBBARD.

Report of the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents. *Chairman,* STUART MUDD, M.D.

Report of the Laboratory Section Representative on the Commission for the Study of Biological Stains. *Chairman,* WILLIAM D. STOVALL, M.D.

TUESDAY, 9:30 A.M.

LABORATORY (Cont.)

Report of the Section Archivist. *Chairman*, AUGUSTUS B. WADSWORTH, M.D.

Antibiotic Substances, Production by Microorganisms, Nature and Mode of Action. SELMAN A. WAKSMAN, PH.D.

The Rôle of the Public Health Laboratory in Gas Defense. EUGENE W. SCOTT, PH.D.

The Problem of Biologic Nonspecific Reactions in the Serology of Syphilis. JOHN A. KOLMER, M.D.

Discussion. JOHN F. MAHONEY, M.D.

ENGINEERING SECTION, CONFERENCE OF STATE
SANITARY ENGINEERS, AND CONFERENCE OF
MUNICIPAL PUBLIC HEALTH ENGINEERS

Joint Session—Madhattan Room

Presiding: A. H. WIETERS and W. SCOTT JOHNSON.

Report of the Committee on Industrial Sanitation. *Chairman*, W. SCOTT JOHNSON.

Report of the Committee on Municipal Public Health Engineering. *Chairman*, SOL PINCUS, C.E.

Report of the Committee on Sewage Disposal. *Chairman*, LANGDON PEARSE.

Report of the Committee on Shellfish. *Chairman*, L. M. FISHER, C.E.

Some Results of Swimming Pool Disinfection with Bromine. CHAUNCEY A. HYATT, and EDWARD A. PISZCZEK, M.D.

FOOD AND NUTRITION

First Session—Parlor 1

Presiding: IRA A. MANVILLE, M.D., *Chairman*.

NUTRITIVE VALUE OF PRESERVED FOODS

Nutritive Value of Canned Vegetables and Fruits. JAMES F. FEASTER, PH.D.

Effect of Preparation for Freezing, Freezing and Storage on the Vitamin Content of Vegetables. JENNY MCINTOSH, PH.D.

Effect of Dehydration on Vitamin Content of Vegetables. JAMES C. MOYER, PH.D.

Nutritive Value of Brined and Fermented Vegetables. IVAN D. JONES, PH.D., and JOHN L. ETHELLE, PH.D.

Nutritive Value of Canned and Dehydrated Meat and Meat Products. E. E. RICE, PH.D.

The Decrease of Vitamin C in Evaporated Milk and Means of Preventing It. F. J. DOAN, and D. V. JOSEPHSON.

TUESDAY, 9:30 A.M.

FOOD AND NUTRITION (Cont.)

Section Business.

Report of the Secretary. MARIETTA EICHELBERGER, PH.D.

Report of the Coördinating Committee. *Chairman*, F. C. BLANCK, PH.D.

Microbiological Examination of Meat and Cereal Products. (Report of the Committee on Microbiological Examination of Foods.) *Chairman*, HARRY E. GORESLINE, PH.D.

The Growth of Nutrition as a Science. (Report of the Committee on Nutritional Problems.) *Chairman* C. G. KING, PH.D.

Food Conservation. (Report of the Committee on Foods.) *Chairman*, BERNARD E. PROCTOR, PH.D.

Report of the Joint Committee on Analyzing Frozen Desserts. *Chairman*, FREDERICK W. FABIAN, PH.D.

Changes in Trends in the Dairy Industry as a Result of the War. (Report of the Committee on Milk and Dairy Products.) *Chairman*, J. A. KEENAN, PH.D.

Report of the Committee on Food Utensil Sanitation. *Chairman*, GEORGE J. HUCKER, PH.D.

Status of the Members of the B. Complex. (Report of the Committee on Assay of Foods.) *Chairman*, HENRY T. SCOTT, PH.D.

Report of the Committee on Membership and Fellowship. *Chairman*, RACHAEL REED.

Election of Officers.

Notc: There will be a meeting of the Section Council immediately following this session.

PUBLIC HEALTH EDUCATION

First Session—Salle Moderne

Presiding: EDNA A. GERKEN, *Chairman*.

DISCOVERY OF NEW RESOURCES FOR HEALTH EDUCATION
IN WARTIME

Chairman: HELEN MARTIKAINEN.

The Use of Volunteers. MARY P. CONNOLLY.

Preparing High School Students for Community Service. GRAHAM L. DAVIS.

The OCD Block Plan. HOWARD Y. MCCLUSKY, PH.D.

Health Education in Japanese Relocation Camps. SALLY LUCAS JEAN.

Resources of Industry for Health Education. HOMER N. CALVER.

Discussion. CARL A. WILZBACH, M.D., and KENNETH D. WIDDEMER.

Section Business.

TUESDAY, 9:30 A.M.

PUBLIC HEALTH NURSING

First Session—Georgian Room

Presiding: ELLA E. McNEIL, R.N., Chairman.

Section Business.

SIGNIFICANCE OF TODAY'S EXPERIENCES FOR FUTURE PUBLIC
HEALTH NURSING PRACTICE

Scope of Service. Speaker to be announced.

Personnel—Education and Accreditation. Speaker to be announced.

Administration of Public Health Nursing Services. Speaker to be announced.

Summary. Speaker to be announced

EPIDEMIOLOGY

First Session—Parlor 2

FOOD AND NUTRITION, MATERNAL AND CHILD HEALTH, PUBLIC HEALTH NURSING, AND SCHOOL HEALTH SECTIONS

Joint Session—Parlors B and C, and Conference Room 3

HEALTH STANDARDS FOR DAY CARE CENTERS FOR CHILDREN

This will be conducted as three simultaneous round tables, each with experts in the fields of clinical pediatrics, public health nursing, nutrition, early childhood education, child guidance, social work, and sanitary engineering. While the discussion in all three instances will revolve around the needs of the child, of the family, and of the community, there will be different prime orientations. One table will approach the problem chiefly from the state level, one from the point of view of the large city, and one with regard to the small city. Since space will be limited sharply, it will be essential to make reservations in advance by mail. It is requested that persons desiring to attend one of these round tables signify this desire by writing to DR. MYRON E. WEGMAN, *Acting Chairman*, Maternal and Child Health Section, 411 East 69th Street, New York 21, N. Y., indicating their preference.

Participants:

LEONA BAUMGARTNER, M.D.
JOSEPH I. LINDE, M.D.
A. CLEMENT SILVERMAN, M.D.
MILTON I. LEVINE, M.D.
DOROTHY BAKER
ANNA DEPLANTER BOWES

MARY A. SWEENEY
DOROTHEA BEHM
ERNEST G. OSBORNE, PH.D.
AMY HOSTLER
ARNOLD L. GESELL, M.D.
WILMER SCHULZE

PUTTING MERIT INTO THE MERIT SYSTEM

Club Room

An informal discussion among personnel officers, members of the Association's Merit Systems Unit, and others interested.

THURSDAY, 9:30 A.M.

ENGINEERING

Point of View. CARL A. WILZBACH, M.D.

Implications of the Victory Corps Program from the Educator's Point
of View. JOHN LUND.

Report of the Conclusions of the Workshop Session on Adjustments
of School Health Personnel in Wartime.

THE TECHNICAL EXHIBITS

MEZZANINE AND FOYERS, HOTEL PENNSYLVANIA

As befits a Wartime Conference, the Twenty-fifth Health Exhibit is streamlined and of the utmost simplicity in its arrangement and decor. Exhibitors are using limited space to bring practical information to health workers. They describe their exhibits as follows:

A. S. ALOE COMPANY

ST. LOUIS, MO. Nos. 71 AND 72

Laboratory apparatus and public health equipment of interest to current wartime problems; blood plasma apparatus of the most modern design for the taking and administration of blood, adaptable to large-scale operation or to small blood bank procedures; serological and bacteriological equipment; new and recent items of interest.

A capable member of the company will be present to give information on priorities and recent regulations for obtaining essential laboratory and public health medical equipment.

AMERICAN CAN COMPANY

NEW YORK, N. Y. Nos. 18 AND 19

The American Can Company will feature the second edition of the Canned Food Reference Manual—a publication of its research laboratories. Greatly expanded in size (over 500 pages) as well as in scope, this edition contains a compilation of the latest findings of research on canned foods, canning procedures, food essentials, modern dietary practices, nutritional and public health aspects. Over 100 illustrations dot the text. Of special interest to the public health official will be the numerous photomicrographs of vitamins embodied in the chapter on "Chemistry of the Vitamins," information on cans and canned foods in the light of wartime restrictions, and 200 pages of tables and charts in the appendix. As in the past it is presented gratis to members of the American Public Health Association and members of the medical profession. Public health officials may make their requests for copies by registering in CANCO'S booths Nos. 18 and 19.

THE AMERICAN JOURNAL OF NURSING

NEW YORK, N. Y. No. 56

Changes without precedent are taking place in nursing as a result of war, and these changes, in all their implications for the post-war future, are recorded, month by month, only in the American Journal of Nursing.

The Journal's publishers take especial pride in the fact that thousands of public health nurses keep informed through its pages, and that, among all its subscribers, of fifteen or more years' standing, public health nurses occupy first place.

BALTIMORE BIOLOGICAL LABORATORY

BALTIMORE, MD. No. 4

Exhibit of dehydrated bacteriological culture media and new peptones. Demonstration of B-B-L Desoxycholate, Desoxycholate Citrate Agars and Selenite-F Enrichment for the isolation of intestinal

pathogens. B-B-L Anaerobic Agar and Brewer Petri dish cover for surface cultivation of anaerobes. B-B-L Thioglycolate Medium for sterility testing of biologies. Anaerobic Apparatus and Pipetting Machine.

BECTON, DICKINSON & COMPANY

RUTHERFORD, N. J. No. 2

Becton, Dickinson will have on display syringes and needles used for blood taking, blood tests and transfusion. Data on the conservation and standardization of instruments used in this work will also be available.

THE BORDEN COMPANY

NEW YORK, N. Y. No. 51

In a graphic and interesting manner, the exhibit of The Borden Company will explain the problem of "supply and demand" of dairy products for 1943. The anticipated amounts needed by the army and lend-lease commitments and civilians will be compared with the amount of milk expected to be produced in 1943.

CAMEL CIGARETTES—MEDICAL RELATIONS DIVISION

NEW YORK, N. Y. Nos. 57 AND 58

CAMEL Cigarettes will exhibit large detailed photographs of equipment used in comparative tests of the five largest-selling brands of cigarettes. Dramatic visualization of nicotine absorption in the human respiratory tract from cigarette smoke will be demonstrated. International news with the CAMEL Cigarette Trans-Lux "Flash Bulletins," may be seen while enjoying a supply of slow-burning CAMEL Cigarettes.

CARNATION COMPANY

OCONOMOWOC, WIS. No. 67

You are invited to visit the Carnation Company booth, No. 67, where you will find presented some interesting information on the various uses of Irradiated Carnation Milk for infant feeding, child feeding, and general diet purposes. Valuable literature will also be available for distribution.

CARWORTH FARMS, INC.

NEW CITY, N. Y. No. 33

This exhibit will demonstrate that mice, similar externally, may be very different, one from another. Litters will be shown derived from matings of randombred and purebred stocks. It will be shown that, not only is the cost of an experiment using miscellaneous heterozygous animals much greater than when selectively bred homozygous animals are used, but also with the latter the results are far more accurate statistically. Diet and its relation to uniformity will be discussed.

CHURCH & DWIGHT COMPANY, INC.

NEW YORK, N. Y. No. 32

Twenty-five years before the first meeting of The American Public Health Association, Church and Dwight Company pioneered in first producing Bicarbonate of Soda in the Western Hemisphere.

For nearly a century, this company has endeavored to make this important product available at low cost.

Today, Arm & Hammer Bicarbonate of Soda, known generally as Baking Soda, can be found in nearly every household. The low cost, purity, and availability of Arm & Hammer, and the fact that it is approved as a dentifrice by the American Dental Association Council, are reasons so many Health Officers recommend it in their Dental Health Educational work.

CLAY-ADAMS COMPANY, INC.

NEW YORK, N. Y. No. 64

Laboratory Instruments and Supplies including the cardboard slide mailers, centrifuges, blood and other counters, Gold Seal slides and cover glasses, agglutination slides, slide boxes and specialties for microscopy and laboratory use will be displayed.

Also Educational Material including anatomical charts, skeletons, demonstration skulls, Ayers and other obstetrical manikins, Chase Hospital Dolls. Medical and Surgical Specialties including Cacoprene (synthetic rubber) catheters, drains, tubes, utility forceps, Justrite Elastic Dressing, and Fracture Splints are included in the exhibit and a Medichrome Library of 2 in. x 2 in. Kodachromes on medical and nursing subjects including tropical medicine, normal histology, nursing procedures, and others.

THE COCA-COLA COMPANY

ATLANTA, GA. Nos. 28 AND 29

Coca-Cola will be served to the delegates with the compliments of The Coca-Cola Company.

CORNING GLASS WORKS

CORNING, N. Y. No. 40

The Corning Glass Works will display various types of Laboratory Glassware mounted on a suitable panel. This exhibit will include "Pyrex" Brand Blood Gas Apparatus, Centrifuge Tubes and Bottles, Culture Dishes, Tubes and Flasks, Pipettes, and Blood Bank Bottle. A few samples of "Pyrex" Brand Lifetime Red Low Actinic Ware, "Pyrex" Brand Fritted Ware and "Vycor" Brand Ware Fabricated of 96% Silica Glass No. 790, will also be shown.

THE CREAM OF WHEAT CORPORATION

MINNEAPOLIS, MINN. No. 17

Both Enriched 5-Minute and Regular Cream of Wheat will be on display. A convenient and completely revised Vitamin chart and Recipes for the use of Cream of Wheat as a meat-extender will be available in quantities for class use.

Zing, stabilized wheat germ, will also be on display. It is made from high vitamin germ, requires no refrigeration, and is economically priced.

DIFCO LABORATORIES, INC.

DETROIT, MICH. Nos. 49 AND 50

This is an exhibit of dehydrated culture media prepared according to the formulac of the American Public Health

Association's "Standard Methods of Water Analysis" and "Standard Methods for the Examination of Dairy Products," as well as other media of particular interest in public health bacteriology.

Bacto-S S Agar, Bacto-MacConkey Agar and other media for isolation and identification of members of the typhoid-paratyphoid-dysentery group will be demonstrated.

EFFERVESCENT PRODUCTS, INC.

ELKHART, IND. No. 10

Demonstration of urine-sugar analysis by the new Clinitest Tablet Method—reliable, simple, fast, single tests being made in less than one minute. A sensitive qualitative test giving dependable quantitative estimations up to 2%.

The same chemical principles involved in the standard copper-reduction methods are the basis of Clinitest—except external heat is eliminated as the Clinitest Tablet itself generates the required heat.

EIMER AND AMEND

NEW YORK, N. Y. No. 38

The major theme of the Eimer and Amend exhibit will be based on the reagents and apparatus necessary to carry through on the major important water analyses, as outlined in the A.P.H.A. Eighth Edition of Standard Methods for the Examination of Water and Sewage. This will include instrumental methods now in use in some water laboratories as well as specific reagents, such as standard soap solution, Nessler reagent, stable starch solution, E. & A. Karl Fisher Reagent solution, etc. A few selected modern, efficient laboratory instruments of use to clinical laboratories will also be on display and in operation.

EISELE & COMPANY

NASHVILLE, TENN. No. 37

Visit Booth No. 37 and see the new "Eisele Temp-Guard Baby Bottle" which will be on display. This bottle is designed to remove the guesswork from baby's feeding and to protect baby's health. Eisele & Company will also have on display their Clinical Thermometers including the glass case Self-Sterilizing Thermometer, Green Plungered Hypodermic Syringes, Hypodermic Needles, Eco Sanelastic Bandages, elastic without rubber, and other specialties.

J. H. EMERSON COMPANY

CAMBRIDGE, MASS. No. 22

The Emerson Resuscitator, Inhalator and Aspirator, in models suitable for use by Marine and other hospitals, industrials and the Armed Forces will be shown. Another feature will be the new Hot Pack apparatus for the rapid and neat preparation of all hot packs, which has received a wide acclamation in the hospital field. Also included will be the well known Emerson Respirator with its many features including the intermittent aspirator and automatic alarms.

EVAPORATED MILK ASSOCIATION

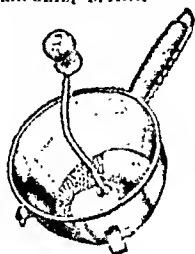

CHICAGO, ILL. No. 63

Visit the Evaporated Milk Association booth to inspect educational material for nutrition programs. Material covers infant feeding, preschool feeding, low-cost family feeding, and quantity food preparation for industrial feeding, school lunches, canteen feeding and related ac-

tivities. Registration at the booth will assure that sample copies will be sent to you. Members of the Association technical staff will be on hand to answer questions on evaporated milk nutritive properties, availability and uses—war and civilian.

FOLEY MANUFACTURING COMPANY

MINNEAPOLIS, MINN. No. 6

Representatives in Booth No. 6 will welcome an opportunity to demonstrate to members how practical the Foley Food Mill (declared a civilian essential) is for straining all fresh cooked vegetables and fruits for babies and adults on smooth diets. A special offer will be made to all members during the Convention.

GENERAL ELECTRIC X-RAY CORPORATION

CHICAGO, ILL. No. 55

Since mass x-ray chest surveys with miniature films is a widely discussed subject among public health authorities these days, may we suggest that you take opportunity during this meeting to discuss with us the G-E Photo-Roentgen Unit. You'll be interested in learning about the many G-E installations now operating in all sections of the country, not only in hospitals and clinics, but also in busses and trailers which make it possible to include conveniently the smallest outlying district in these surveys. Ask particularly about the 4 by 5-inch stereo chest films produced with this apparatus. And after you have seen them under illumination in the Orthostereoscope specially designed for this purpose, we're sure you will agree that this development for x-ray chest survey is a timely one and should greatly augment anti-tuberculosis field work.

GERBER PRODUCTS COMPANY

FREMONT, MICH. No. 15

Gerber's CEREAL FOOD and STRAINED OATMEAL, two special infant cereals, are thoroughly cooked, dried, and ready to serve merely upon addition of milk or formula. They are both fortified in not only thiamin but other members of the vitamin B complex and in iron. These, as well as the other Gerber Baby Foods will be on display. Literature for distribution to mothers and adults on restricted diets and also professional material are at the booth for your inspection.

THE GILLILAND LABORATORIES, INC.

MARIETTA, PA. No. 16

The Gilliland Laboratories will have on display at Booth No. 16 a complete line of Biological Products. This firm gives special attention to supplying Biological Products to State, City and County Boards of Health, Hospitals and Institutions. The representative in charge of this exhibit will be pleased to answer any inquiries.

GRADWOHL SCHOOL OF LABORATORY TECHNIQUE

ST. LOUIS, MO. No. 54

This exhibit is designed to show one of our teaching methods, namely, a descriptive cabinet on the mechanism of the Rh factor and its importance in blood transfusion. The exhibit will also include a number of high grade laboratory reagents, particularly Giemsa stain manufactured by this organization, a Commission-certified product.

INTERNATIONAL CELLULOCOTTON PRODUCTS COMPANY

CHICAGO, ILL. No. 45

This exhibit will feature an up-to-the-minute program on menstrual education for women in industry.

For women workers: "That Day Is Here Again"—a 16 page illustrated booklet. Debunks old superstitions. Covers important Do's and Don'ts. Gives posture improving exercises. Stresses need for personal care.

For industrial nurses and advisers—Menstrual charts—a complete visual explanation of menstruation. Also: "Just to Review"—a technical explanation of menstruation—clear, modern, authoritative.

The International Cellulocotton Products Company manufactures Kotex and Fibs.

KELLOGG COMPANY

BATTLE CREEK, MICH. No. 62

The Kel-Bowl-Pac now featured in the Kellogg Variety Package is an important addition to the snack menu and for the school lunch, because of its convenience. The PACKAGE is the BOWL!

All Kellogg ready-to-eat cereals either are made from whole grains or are restored to whole grain nutritive value. Kellogg's Pep Whole Wheat Flakes is fortified with extra vitamins B₁ and D. One serving (1 ounce) furnishes $\frac{1}{4}$ the daily requirements for adults for B₁ and sufficient vitamin D to meet all daily requirements for that vitamin.

KIMBLE GLASS COMPANY

VINELAND, N. J. No. 11

There will be shown Kimble Blue Line Exax and Normax Precision Retested graduated ware and Kimble  Brand laboratory glassware and apparatus.

Especially featured will be bottles and other glass parts for preparation and injection of parenterals, particularly blood plasma. These are highly resistant to chemical attack, offering maximum assurance of unimpaired quality and clinical safety.

All material obtainable from laboratory supply houses will be on display.

LEDERLE LABORATORIES, INC.

NEW YORK, N. Y. No. 3

Conforming with the general subject of American Public Health Association's Wartime Public Health Conference, Lederle Laboratories will feature in Booth No. 3 some of their outstanding products of special value in wartime.

The Vollmer Tuberculin Patch Test will be spotlighted. Other products to be featured are Blood Grouping Sera, used in identifying blood types for blood transfusions, Sulfadiazine, "The Drug of the Year," for infectious, Tetanus Toxoid, Typhus Vaccine and Blood Plasma. Literature and samples which have to do with these products will be available through staff attendants at the Booth.

E. LEITZ, INC.

NEW YORK, N. Y. No. 41

Technical instruments which E. Leitz manufactures and distributes will be shown. One is Leitz Photo-Electric Clinical Colorimeter, widely used in hospitals, institutions, and by physicians for the accurate and quick quantitative determination of constituents of body fluids; another is the Leitz G & D Electro Titrator. This greatly facilitates the laboratory procedure. The principle it employs is that the end point is determined by a change in voltage of two suitably selected electrodes dipping into the solution which is being titrated, instead of being determined by a change of color of an indicator or of one of the reagents employed in the titration. There may also be available an instrument known as the Leitz Müller Photometer, a highly precise photo-electric research filter photometer which is easy to operate. The Leitz Desk Viewer for the viewing of 2x2" Kodachrome slides and 35 mm. film strips, and also the VIII-S Projector for projecting 2x2" slides and 35 mm. film strips, will be displayed, and, depending upon availability, Leica Camera equipment for macrophotography.

LILY-TULIP CUP CORPORATION

NEW YORK, N. Y. Nos. 59 AND 60

Lily-Tulip cups and containers have gone to war. This display is a pictorial review illustrating their economy and health protection value in the war effort—their use in mass feeding in the armed services, at post exchanges and ship's service, at service clubs, in hospitals, at shipyards and war production plants for feeding and safe water drinking—for food packaging, food rationing, and many other valuable uses important today.

J. B. LIPPINCOTT COMPANY

PHILADELPHIA, PA. No. 27

The exhibit of J. B. Lippincott Company will feature the new "Essentials of Industrial Health" by Dr. C. O. Sappington as well as another new and important work, "Essentials of Syphilology" by Dr. R. H. Kampmeier. Other important books on display will be Putnam's "Convulsive Seizures," a new manual for patients, the new second edition of Rigler's "Outline of Roentgen Diagnosis," Beardwood and Kelly's "Simplified Diabetic Management," and Girard's "Home Treatment of Spastic Paralysis." Be sure to see them.

LYONS ALPHA PRODUCTS CO., INC.

NEW YORK, N. Y. No. 34

The famous Lyons Sanitary Cream and Milk Dispensers "with the patented cream and milk faucets" will be exhibited. The outside body of these is white porcelain enamel; inside body, tinned copper. The cream dispenser is made from 6 quart to 20 quart size, and the milk dispensers from 6 to 40 quarts. The new Alpha 2 quart Cream Dispenser, and the Alpha Sterilizers will also be displayed.

THE MACMILLAN COMPANY

NEW YORK, N. Y. No. 53

Public Health Workers will find of special interest, at the Macmillan Booth 53, the new book by Dr. William R. P. Emerson, **HEALTH FOR THE HAVING**. It recommends itself as a valuable aid in public health work. Field workers

and administrators alike look to **COMMUNICABLE DISEASE CONTROL**, by Anderson-Arnstein, and **PUBLIC HEALTH ADMINISTRATION IN THE UNITED STATES**, by Dr. Smillic, for answers on public health questions. Among other books will be the popular **SO BUILD WE**, by Mary S. Gardner, **THE PUBLIC HEALTH NURSE IN ACTION**, by Marguerite Wales, and **RABIES**, by Dr. Leslie T. Webster.

THE MAICO CO. INC. OF N. Y.

NEW YORK, N. Y. No. 39

The precision hearing test instruments used by Army, Navy, Airlines, and ear physicians for hearing tests and examinations will be displayed by the MAICO CO. which provides more than 90% of all these precision hearing test instruments used in America. The new **HEARING DISABILITY CALCULATOR** and **Percentage of Loss Indicator**, available to all visiting physicians and public health officials, provides a quick and ready means of calculating any individual's exact hearing disability in accordance with the official standards of the American Medical Association.

THE MEDICAL BUREAU

CHICAGO, ILL. No. 48

In Booth No. 48, M. Burneice Larson offers the facilities of the Medical Bureau, an organization acting as counselor in problems of medical personnel to physicians and executives in the medical, industrial, and public health fields. The records of physicians who have specialized in the various branches of medicine, or those who have completed their training recently, as well as the records of administrators, registered nurses, bacteriologists, scientific workers, social workers, and dietitians, are available to those interested in the completion or reorganization of their staffs.

MERCK & CO., INC.

RAHWAY, N. J. No. 8

A set of vitamin reviews in a convenient slip-cover container designed for ready reference in library or bookcase is available at the Merck booth. In addition, information and literature on the arspenamines and tryparsamide may be obtained, and also a sample of *Cuprex*, widely used today for controlling the ever-present public health problem of pediculosis. A 15 minute application of *Cuprex* destroys the nits as well as the lice.

METROPOLITAN LIFE INSURANCE COMPANY

NEW YORK, N. Y. No. 46

The Welfare Division will maintain Consultation Headquarters in Booth 46. Members of its staff will be available for discussion of their special interests, and the use of the Company's health education materials. They hope not only to offer information but to receive suggestions from those active in these special fields and experienced in stimulating community action.

The subjects and times of the consultation periods are:

Rheumatic Fever Campaign, Monday P.M.; Nursing, Tuesday A.M.; Safety—"On and Off the Job," Tuesday P.M.; School Health Education, Wednesday A.M.; Industrial Hygiene, Wednesday P.M.; Community Health Campaigns—Films—Exhibits, Thursday A.M.; Nutrition, Thursday P.M.

MINE SAFETY APPLIANCES COMPANY

PITTSBURGH, PA. No. 35

In the M.S.A. booth, there will be featured a complete line of personal and plant protective equipment including: gas-detecting and indicating instruments; dust-sampling and counting instruments; dust, fume, and paint respirators; gas masks; oxygen breathing apparatus; inhalators; Skullgard protective hats; first aid kits and materials; goggles; asbestos and chrome leather protective clothing; Ear Defenders; Lilly Dacré Hats for women industrial workers; Fend Barrier Protective Creams and Hand Lotions; Foille, the modern treatment for burns; and the Goggle Cleaning Station. M.S.A. representatives from both office and field will be in attendance to demonstrate this equipment and discuss your safety problems.

THE C. V. MOSBY COMPANY

St. Louis, Mo. No. 30

The C. V. Mosby Company extends to all attending the Wartime Conference of the American Public Health Association, a cordial invitation to look over its publications which will be on display at Booth No. 30. Books which will be of interest to public health workers include Turner "Personal and Community Health," Turner-McHose "Effective Living," Top "Handbook of Communicable Diseases," Lynch "Communicable Disease Nursing," and Cameron "Bacteriology of Public Health."

NATIONAL DAIRY COUNCIL

CHICAGO, ILL. Nos. 12 AND 13

Health education materials produced in the interest of nutrition in the war program are on display in the National Dairy Council booths—featuring information on the nutritive values of milk, ice cream, and the other dairy products. Posters and booklets which can be used in many phases of the public health program are available for examination. A catalogue of all materials will be sent to persons registering at the booth.

NATIONAL LIVE STOCK AND MEAT BOARD

CHICAGO, ILL. No. 61

The National Live Stock and Meat Board will have a nutrition exhibit showing the importance of meat in the adequate diet. Nutrition literature including the Nutrition Yardstick will be displayed.

OVAL WOOD DISH CORPORATION

TUPPER LAKE, N. Y. No. 9

Oval Wood Dish Corporation will again display in Booth 9 its complete line of RITESPOONS and RITEFORKS—sanitary single service eating utensils made of naturally pure wood. These spoons and forks are playing an important part in the sanitary feeding of defense workers in industrial plants throughout the country and in the feeding of our armed forces both here and abroad. They are considered one of the most outstanding single service items today. You are cordially invited to register for samples and literature.

PET MILK SALES CORPORATION

St. Louis, Mo. Nos. 69 AND 70

A complete display of material illus-

trating the time-saving Pet Milk services available to hospitals and physicians. Specially trained representatives will be in attendance to give you information about the production of Pet Milk and its use for infant feeding. Miniature cans will be given to members visiting the exhibit.

PARKE, DAVIS & COMPANY

DETROIT, MICH. No. 68

At the Parke-Davis Exhibit, which has been streamlined because of present wartime requirements, you will find many new and scientific Pharmaceutical and Biological Products. Included in this display are such outstanding preparations as Phemerol, a relatively non-toxic and non-irritating germicide and antiseptic; Vitamin Products; Sulfa Drugs; Despeciated Antitoxins; and numerous other outstanding products of timely interest. Able and courteous members of the Parke, Davis & Co. Staff are in daily attendance to serve you.

PETROGALAR LABORATORIES, INC.

CHICAGO, ILL. No. 7

You are cordially invited to visit the Petrogalar exhibit where a new and enlightening story on Petrogalar, an aqueous suspension of mineral oil, will be related. Beautifully colored anatomical drawings and new literature may be had upon request from our professional representatives who will be in constant attendance.

PHILIP MORRIS & CO., LTD., INC.

NEW YORK, N. Y. No. 31

Philip Morris & Company will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes. Their representative will be happy to discuss researches on this subject, and problems on the physiological effects of smoking.

POWERS X-RAY PRODUCTS, INC.

GLEN COVE, N. Y. No. 1

This exhibit features the Rapid Paper Film Method of X-raying chests of large groups of persons under the supervision of local physicians, without investment in chest x-ray equipment; demonstrates the diagnostic clarity of the 14 x 17 paper film in comparison with 14 x 17 transparent base film; and shows a typical roll of one hundred radiographs on a mechanical viewer.

THE PROCTER & GAMBLE COMPANY

CINCINNATI, OHIO No. 21

At the Procter & Gamble booth, visitors will see demonstrated some of the qualities of Ivory Soap which have resulted in Ivory's being recommended, "by more doctors than all other brands of soap together."

Copies of Ivory's new baby booklet, "Bathing Your Baby the Right Way," prepared with the cooperation of a world famous maternity center, will be available free of charge to visitors.

W. B. SAUNDERS COMPANY

PHILADELPHIA, PA. No. 14

The W. B. Saunders Company welcomes you to its exhibition at Booth No. 14 of its complete line of books on Medicine, Nursing, and Health. Among these will be new editions of McLester's Nutrition and Diet, Bower and Pilant's Communicable Diseases, Todd and Sanford's Clinical Diagnosis, and the following new books: the Military Medical and Surgical Manuals, the Manual of Industrial Hygiene, Stieglitz' Geriatric Medicine, and Vincent and Breckenridge's Child Development.

THE SEALRIGHT COMPANY, INC.

FULTON, N. Y. Nos. 42, 43 AND 44

"Milk Protection Is Health Protection" is the theme of Sealright's 1943 exhibit, which presents the sanitation reasons for sealing milk bottles with hoods which provide complete pouring lip protection. Also presented is the complete series of advertising messages currently sponsored by Sealright in national magazines, dramatizing outstanding accomplishments in public health achievements.

SEALTEST, INC.

NEW YORK, N. Y. Nos. 23 AND 24

The exhibit of Sealtest, Inc., a Division of National Dairy Products Corporation, will explain the work of this organization in dairy products research and inspection of ice cream, milk and dairy product production. The activities of the Sealtest Laboratory Kitchen, Consumer Service and Educational Department of Sealtest, Inc., in promoting the use of dairy products in the home will also be featured.

SHARP & DOHME

PHILADELPHIA, PA. Nos. 25 AND 26

Sharp & Dohme will have their display at Booths Nos. 25 and 26, featuring a new sulfonamide, Sulfamerazine 2-sulfanilamido-4-methylpyrimidine, "Sulfasuxidine" succinylsulfathiazole, "Lyovac" Normal Human Plasma, and biological products for active immunization. A cordial welcome awaits all visitors. Capable, well-informed representatives will be on hand to furnish information on Sharp & Dohme products.

E. R. SQUIBB & SONS

NEW YORK, N. Y. Nos. 65 AND 66

The exhibit of E. R. Squibb & Sons features the rôle that recently developed agents play in the conquest of the venereal diseases. Special emphasis will be given to Clorarsen, an effective anti-syphilitic agent, Lygranum S. T. and Lygranum C. F., antigens of chick embryo origin for use in the skin test and complement-fixation test, respectively, for lymphogranuloma venereum. Information on the chemotherapeutic agents used in the treatment of gonorrhea will be included. Members of the medical and professional service staffs will be in attendance for consultation.

STANLEY SUPPLY CO.

NEW YORK, N. Y. No. 36

The improved Davidson Incubator for Premature Infants will be featured. This unit is completely oxygenated and humidified. Be sure and ask for a demonstration of the Davidson Incubator.

WALLACE & TIERNAN CO. INC.

NEWARK, N. J. No. 73

Because of war conditions the Wallace & Tiernan Exhibit will be confined to photographic displays of their various chlorinating and water treatment devices in actual use.

WHITE LABORATORIES, INC.

NEWARK, N. J. No. 5

Within recent years tremendous advances in vitamin research have added a wealth of clinical data to our knowledge of nutrition.

The intense interest of the laity in the vitamins—often, unfortunately, confused and misled by unauthoritative lay advertising and uninformed "information"—can be properly controlled by the physician's interpretation of the actual usefulness of the vitamins to his patients.

In Booth No. 5, White Laboratories, Inc., presents its complete line of ethically promoted, clinically reputable vitamin preparations. Qualified representatives are in attendance to discuss with you the use of White's products in vitamin prophylaxis and therapy. Descriptive literature is available for your review, and a cordial welcome awaits you.

WINTHROP CHEMICAL COMPANY, INC.

INDUSTRIAL DIVISION

NEW YORK, N. Y. No. 47

Headquarters for information concerning ROCCAL and allied cationic, germicidal detergents. Increased use of ROCCAL during the past two years in food processing plants, dairies, restaurants, and in many other applications, has given a fund of new data which should be of interest to every health officer and sanitarian.

Technical attendants at the booth will be very happy to discuss bacterial problems and make specific recommendations for solving these problems through the use of cationic detergents.

WYANDOTTE CHEMICALS CORPORATION

WYANDOTTE, MICH. No. 20

The same safe, speedy Wyandotte Products used by the Armed Forces will be featured. Wyandotte Steri-Chlor for germicidal operations; Wyandotte G.L.X. for equipment cleaning; Wyandotte Cannery Alkali for alkaline peeling before dehydration; Wyandotte Alkalies for bottle washing; Wyandotte Keego, Cherokee, and Poma for dishwashing operations; Wyandotte Calcium Chloride for dustlaying.

The following Wyandotte Representatives will attend: V. R. Jones and P. W. Soderberg of the home office, Sales and Technical Service, Wyandotte; and A. J. Bettelheim of the New York office.

AMERICAN PUBLIC HEALTH ASSOCIATION BOOK EXHIBIT

CONDUCTED BY THE NATIONAL HEALTH
LIBRARY FOR THE A.P.H.A.
BOOK SERVICE

CONFERENCE ROOM 7

There will be on display several hundred of the newer public health books of all publishers. Books in all public health categories will be included, classified under the following heads:

Preventive Medicine and Public Health
Laboratory
Food and Nutrition
Vital Statistics
Public Health Engineering
Industrial Hygiene
Mental Hygiene
Social Hygiene and Eugenics
Tuberculosis
Personal Hygiene
Child, Maternity and School Hygiene
Health Education
Nursing
Reference, Medical History, etc.
A.P.H.A. Publications

A five-foot shelf of basic books for public health workers will be featured. Members of the National Health Library staff will be on hand to answer questions, to make recommendations, and to provide information about books, the A.P.H.A. Book Service, and about the National Health Library Services.

HEALTH EDUCATION CENTER

CONFERENCE ROOM 8

The Health Education Center will be conducted again this year by the National

Publicity Council for Health and Welfare Services (formerly Social Work Publicity Council). The Center will be open to all delegates for study and consultation.

A library of indexed portfolios will be at hand containing outstanding examples of all types of health educational material: folders, pamphlets, radio scripts, annual reports, photographs, bulletins, and news releases.

Some of the portfolios will contain a miscellany of material in a particular medium. But a majority of them will contain collections of material in every medium on subjects that relate directly to the major topics of discussion at the conference. Sample titles are: "Rationing and Its Effect on the Diets of Mothers and Children," "The Community's Responsibility for Adequate Sanitation Measures," "Diseases of Special Importance in Wartime." Wherever possible, portfolios will not only contain samples of printed publicity materials, but will also include descriptions of how communities were organized for special projects in health education, with statements of how the printed materials were distributed and used.

In addition to the portfolios on display at the Health Education Center, the Publicity Council's entire library at its New York offices will be available to delegates. This library contains samples of publicity and health education material in every medium, and on every subject of interest to health and welfare agencies. Details of these collections may be had at the Health Education Center or by writing in advance to The National Publicity Council, 130 East 22nd Street, New York, N. Y.

Health education experts will be on hand at the Center for consultation with delegates on the particular problems of their communities.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

Tuberculosis Association in large eastern city will accept applications for position on staff as statistical research secretary. Requirements: basic training in vital statistics, ability to plan and carry out statistical studies in the field of public health. One month's vacation. Five day week, with occasional work on Saturdays. Address Box C, Employment Service, A.P.H.A.

PH8-5. For further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

PROVISIONAL BIRTH AND DEATH RATES FOR MAY

The Bureau of the Census, Washington, on July 12 released figures based on reports from 42 states and the District of Columbia indicating birth rates of 20.3 for May, 1943, as against 19.4 for May, 1942. The death rates respectively were 10.5 and 10.0. The infant mortality rate for 40 states and the District of Columbia was 37.1 per 1,000 live births for May and 5.6 per cent lower than the rate for the corresponding month of 1942. For the first 5 months of 1943 the infant mortality rate is computed as 42.5 as compared with 44.7 for the corresponding part of 1942.

Commenting on the causes for the rise in the crude death rate, the bureau states that, although exact information as to the causes is not available, an analysis of a 10 per cent sample of death certificates indicates that the rise is attributable in a large measure to deaths from diseases of older ages, namely the cardiovascular-renal diseases. Also the mortality has been higher than expected for the group of death causes including the prevalent diseases of childhood and for accidents, exclusive of motor vehicle accidents.

A COUNTY PROGRAM FOR THE PREVENTION OF DEAFNESS

According to Dr. Robert H. Riley, Director of the Maryland State Department of Health, Baltimore, Washington County, Md., has inaugurated a program for the prevention of deafness. This program was made possible through a special grant of aid to the Services for Crippled Children, Maryland State Health Department, by the

U. S. Children's Bureau. Previous surveys of school children conducted in Washington County by the Board of Education and the County Health Department revealed that 2.5 per cent of the school children in Washington County had some impairment of hearing. The present program will augment the limited facilities for otolaryngology in the community and will provide for radon therapy for adenoid tissue. The objectives of the program are: (1) Education of parents in the necessity for proper medical care for children with acute otitis media. It is planned to attain this objective through Parent-Teacher Associations, distribution of pamphlets, newspapers, preschool and school medical conferences and home nursing visits. (2) Testing of hearing in public and parochial schools. Children found with impaired hearing will be referred to the clinic. The screening test will be performed by a trained technician from the Frederick School for the Deaf. (3) Regular ear, nose, and throat clinics will be conducted by Dr. Donald F. Proctor from the Johns Hopkins Ear, Nose and Throat Clinic. Special treatment, such as tonsil and adenoid operation and mastoid operations will be done at the Washington County Hospital.

This program is under the direct supervision of Dr. W. R. Willard, County Health Officer, and has the full approval of the County Medical Society. It is a coöperative study by health agencies and medical societies and state board of education, and the private physician has an active part in the program. This program is proving to be one of the most popular programs conducted in the county.

MAINTAINING STANDARDS OF QUALITY
AND SANITARY REGULATIONS FOR
FOOD

The Association of Food and Drug Officials of the United States meeting recently in Denver announced that the Association is opposed to the principle of the lowering of standards of quality and sanitary regulations governing the production, processing, selling, and distribution of foods and food products which prevailed in the respective jurisdictions prior to the present emergency. The resolution was based on the conviction that in certain sections of the country concerted efforts have been made to lower the standards of quality and sanitary regulations governing the production, processing, selling, and distribution of foods and food products.

DR. VONDERLEHR APPOINTED TO PUERTO
RICO AND VIRGIN ISLAND POST

Raymond A. Vonderlehr, M.D., who for 8 years has served as Assistant Surgeon General in charge of the Division of Venereal Diseases of the U. S. Public Health Service, has been appointed, as of July 12, Director of District 6 of the U. S. Public Health Service covering Puerto Rico and the Virgin Islands. Dr. Parran, the Surgeon General, has pointed out that

... while serving as Assistant Surgeon General Dr. Vonderlehr has seen the national effort against the venereal diseases expand from a rear-guard action with limited funds and personnel to an all-out attack in every state, in every large city and in a majority of rural counties. The stimulus of the Venereal Disease Control Act of 1938 has resulted in a nation-wide expansion of facilities and services for the eradication of syphilis and gonorrhea. Appropriations from all sources for venereal disease control work have increased from a few hundred thousand dollars in 1935 to over 18 million dollars in 1943.

Succeeding Dr. Vonderlehr, the appointment of Dr. J. R. Heller, Jr., as Assistant Surgeon General has been announced. Dr. Heller joined the regular

corps of the Public Health Service in 1934, has served in charge of venereal disease activities with headquarters in New Orleans, La., and more recently has been serving as assistant chief of the States Relations Division of the Public Health Service.

DESIGN FOR A HEALTH FLAG

William S. Bailey, Health Officer of Irvington, N. J., has announced that he has obtained Letters Patent for a design for a health flag symbolizing the health movement.

The design consists of a blue background on which a white cross is imposed and over which a red letter H is superimposed.

It is understood that Mr. Bailey plans to make the flag available through arrangements with a manufacturer.

THE LESLIE DANA GOLD MEDAL AWARDED
TO DR. LANCASTER

The National Society for the Prevention of Blindness has announced that the Leslie Dana Gold Medal, awarded annually for outstanding achievements in the prevention of blindness and conservation of vision, will be presented this year to Dr. Walter B. Lancaster of Boston. The selection was made by the St. Louis Society for the Blind, upon recommendation of the Association for Research in Ophthalmology.

Although 80 years of age Dr. Lancaster is said still to be active in his practice as an ophthalmologist in Boston and vicinity where he has rendered long service in this field.

NATIONAL HEALTH LIBRARY APPOINTS
NEW LIBRARIAN

The National Health Library, which is located at 1790 Broadway, New York, N. Y., and which is jointly maintained by the agencies in the National Health Council, has announced the retirement as of July 1 of Isobel L. Towner who has been librarian since

1936. Succeeding Miss Towner the appointment of Eva R. Hawkins has been announced as librarian. Mrs. Hawkins has served as associate librarian for several years.

The attention of members and Fellows of the American Public Health Association is called to the fact that, by virtue of their membership, they are entitled to free access to the library and to counsel with the library staff.

CONFERENCE ON ORTHOPEDIC NURSING

Plans are being completed for the three-session group conference on orthopedic nursing to be held October 11 in New York, N. Y., preceding the War-time Conference of the American Public Health Association. This conference is being planned primarily for nurses actively engaged in orthopedic services. Discussion will center around plans for future adjustments in orthopedic programs.

Morning session 9:30-12:00—"Teaching Responsibilities of the Orthopedic Public Health Nurse"

Afternoon session 2:00-4:30—"Nursing Problems in the Care of Patients with War Injuries"

Evening session 7:30-9:30—"Orthopedic Disabilities of Workers in Industry"

The morning session, because of informal discussion, will be limited to 30. There will be no restrictions on the afternoon and evening sessions.

The conference will be held in the Henry Street Auditorium, 262 Madison Avenue, New York, N. Y. Registration will close October 1 and applications should be sent to Jessie L. Stevenson, Consultant in Orthopedic Nursing, Joint Orthopedic Nursing Advisory Service, 1790 Broadway, New York 19, N. Y.

CHANGES AT GENEVA EXPERIMENT STATION

Dr. Carl E. Ladd of Cornell University, Ithaca, N. Y., shortly before his death, announced that the dairy work

at the experiment station at Geneva is to be discontinued and the herd eventually disposed of. Dr. Ladd explained that budget-making officials of the state have believed that maintenance of herds at both Geneva and Ithaca was uneconomical. The termination of the research at the Geneva institution, which has been a leading dairy research institution among those in North America for many years, is understood not to affect the status of Dr. Robert S. Breed, who has long occupied the position of Chief In Research. Dr. Breed will continue at Geneva until retirement.

Dr. Ladd announced that the experiment station at Geneva will be developed and enlarged as a horticultural research institution. "Any disruption of long established lines of endeavor at an institution like the experiment station is bound to be disturbing, especially so to the individuals concerned. We must be realistic about such things, however, and when readjustments have to be made it is necessary to think in terms of the whole rather than a part. Those of us at Cornell who are charged with the administration of the experiment station at Geneva are definitely committed to a program of expansion of the work of the station along certain well defined lines."

KANSAS PUBLIC HEALTH ASSOCIATION MEETING

The Annual Meeting of the Kansas Public Health Association held in June in Emporia centered around wartime public health problems. Among the speakers from out of the state there were, from the staff of the U. S. Public Health Service, Dr. Joseph W. Mountin, Dr. L. E. Burney, Dr. Maurice A. Roe, Lilly Hagerman, R.N., and O. C. Hopkins, Sanitary Engineer; from the Children's Bureau Dr. Hester B. Curtis and Jane Nicholson, R.N.

The election of the following officers was announced: Dr. D. D. Carr, To-

peka-Shawnee County Health Officer, *President*; Dr. Henry H. Asher, Director Local Health Services, Kansas State Board of Health, *President-elect*; Janet Tidrick, R.N., Nurse Consultant, Kansas State Board of Health, *Vice-president*; Dr. Fred Mayes, Director Child Hygiene Division, Kansas State Board of Health, *Secretary*; Dr. F. C. Beelman, Secretary and Executive Officer, Kansas State Board of Health, *Treasurer*. The Executive Committee includes: Dr. John W. Turner, Wichita-Sedgwick County Health Officer; Dr. Charles A. Hunter, Director Public Health Laboratories, Kansas State Board of Health; and Ruth Henton, R.N., Ilathe, Johnson County Public Health Nurse.

CORRECTION

In the article, "Some Epidemiological Aspects of Tuberculosis Determined by Analysis of Sanatorium Records," appearing in July JOURNAL:

Table 7, page 785, should read:

Age Group	$\frac{\text{Cases}}{\text{Population}} \times 100$
0-14	.017
15-19	.067
20-24	.116
25+	.095
Total	.082

Last paragraph, page 784, should read:

In the age groups 0-14 and 15-19 the rates are approximately 19 and 26 times greater in the clinic population than in the general population; in older ages the rate in the clinic population is 8 to 9 times as great as that in the general population.

Conclusion 3, page 792, should read:

Practically all cases of tuberculosis are diagnosed on single examination; the rate of development of tuberculosis in patients negative on initial examination is 9 times as great as that in the general population. Roy M. SEIDEMAN, M.D.

OCD URGES RECOGNITION OF HEALTH OFFICIALS IN CIVILIAN PROTECTION ORGANIZATION

Operations Letter No. 131, of the Office of Civilian Defense, entitled "The Health Department in Civilian Protection" urges the appointment of health officers to the U. S. Defense Corps. Health officers, with their deputies, division chiefs, and sanitary inspectors, should be members of the U. S. Citizens Defense Corps in order that health and sanitation may be maintained during and after an air raid or other wartime disaster, it is stated.

Plans should be developed by health officers to assure maintenance of safe water, food, and milk supplies, disposal of wastes, sanitation at mass feeding centers, and control of communicable diseases. The *Operations Letter* recommends that health officers select volunteer health deputies for appointment to the staff unit of the Citizens Defense Corps in communities where the health department does not have sufficient personnel to provide sanitary supervision and inspection services in a war emergency.

All health department personnel must complete training in accordance with regulations of the Citizens Defense Corps before they can become members.

DR. ARTHUR THOMAS MC CORMACK DIES

Arthur T. McCormack, M.D., State Health Commissioner and Secretary of the Kentucky State Board of Health, died on August 6 in Louisville of a heart attack. He was 70 years old.

A graduate of the College of Physicians and Surgeons at Columbia University in 1896, Dr. McCormack devoted his career to public health. He became Secretary of the State Board of Health in 1912, succeeding his father, the late Dr. Joseph Nathaniel McCormack. He founded *The Kentucky Medical Journal* in 1901 and was editor and director thereafter. He organized

the School of Public Health at the University of Louisville and was its first dean. He was secretary of the Kentucky State Medical Association for more than 25 years.

Dr. McCormack was elected to membership in the American Public Health Association in 1919, to Fellowship in 1923, and to Life Membership in 1933. He served as a member of the Governing Council and of the Executive Board from 1928 to 1932. He was a Vice-President of the Association in 1933, became President-Elect in 1937, and was inducted into office as President in 1938.

TWO HOLDERS OF FORTY YEAR MEMBERSHIP CERTIFICATES DIE

The deaths of Robert Spurr Weston and John Watson Alvord, both members of forty years' standing in the Association, are regretfully recorded. Both were Consulting Engineers. Both rendered notable service throughout their long professional careers to hundreds of American communities.

Robert Spurr Weston took his degree of Bachelor of Science in 1891, and of Master of Arts in 1894 at Amherst College. Thereafter, he studied at Massachusetts Institute of Technology and at the University of Berlin. From 1912 as a member of the firm of Weston and Sampson, he served states, cities and towns in connection with water supply, water purification, stream pollution, sewerage, sewage and industrial waste treatment. He had been Vice-President of the American Society of Civil Engineers, President of the American Water Works Association, and President of the American Public Works Association. Mr. Weston was elected to membership in the American Public Health Association in 1896 and to Fellowship in 1922. He served as Vice-Chairman of the Engineering Section in 1913 and as Chairman in 1914. He was a member of the Governing Coun-

cil from 1924-1927 and was elected Vice-President of the Association in 1932.

John Watson Alvord was educated at Harvard University Preparatory School and J. W. Hunt's Normal School, Washington. He was awarded an Honorary Degree in Civil Engineering by the University of Wisconsin in 1913. He was a consulting engineer since 1894 to over 300 municipalities on sewerage works, water supply and water power, sewage disposal and appraisal boards. He was President of the American Water Works Association and a member of many engineering societies. Mr. Alvord joined the Association in 1899 and was a Charter Fellow.

SAVEL ZIMAND NAMED ACTING DIRECTOR OF THE BUREAU OF HEALTH EDUCA- TION, NEW YORK CITY DEPARTMENT OF HEALTH

Savel Zimand, who has been an administrative assistant in the New York City Health Department for 9 years has been designated by Health Commissioner Ernest L. Stebbins to be Acting Director of the Bureau of Health Education. Mr. Zimand, recently assigned to the bureau, succeeds Dr. Charles F. Bolduan, first director of the bureau and its head for many years until his retirement in August.

For six years previous to 1934, Mr. Zimand was administrative director of the Bellevue-Yorkville Health Demonstration.

WAR MANPOWER COMMISSION SAFE- GUARDS CIVILIAN NURSING

Paul V. McNutt, Chairman of the War Manpower Commission, announced on July 26 that nurses must be declared nonessential in civilian service before they can be recruited for the armed services.

Mr. McNutt stated that the Nursing Supply and Distribution Unit has become the Nursing Division of the Com-

mission's Procurement and Assignment Service with the same objectives as the divisions of the Procurement and Assignment Service now dealing with dentists, veterinarians, physicians, and sanitary engineers. They involve the recruitment of sufficient nurses to meet the needs of the armed forces and the provision of minimum adequate nursing care for the civilian population.

Recruiting of graduate nurses for the armed services will continue to be handled by the Red Cross, and recruiting of cadet nurses by the U. S. Public Health Service.

The function of the WMC is to determine whether a nurse may be released for military service, and to see that those who remain at home are so distributed as to provide adequate care for civilians.

I. Louise Baker, R.N., has been named assistant to Dr. Maxwell Lapham, executive officer of the Procurement and Assignment Service. She will be assisted by Ruth A. Heintzelman, R.N.

A.M.A. HEALTH EDUCATION

From August 2 through August 6, 29 graduate students under fellowships from the W. K. Kellogg Foundation and the supervision of the U. S. Public Health Service, spent a week of intensive observation, study and demonstration of the health education and related work of the American Medical Association at the Association's headquarters' building in Chicago.

The history, organization, and work of the association were presented in detail as well as the work of each department.

Each student was furnished with an extensive collection of reference materials and each was given opportunity for personal consultation with the head of that association department whose work most interested the student.

THE SCIENCE MOBILIZATION BILL (S. 702)

This bill, which was introduced into the Senate by Senator H. M. Kilgore, has had extended examination by the American Association for the Advancement of Science, with which the American Public Health Association stands in an affiliated relationship. Dr. Isaiah Bowman, President of the A.A.A.S., has announced that the association, through its Council, has gone on record by a vote of 146 to 5 opposing the bill according to the following statement.

After careful consideration of the purposes and provisions of the Science Mobilization Bill (S. 702), the American Association for the Advancement of Science, an organization of nearly 25,000 members (and having 187 associated and affiliated societies with a combined membership of over 500,000 persons whose interests cover broadly all the natural and social sciences) now, through its Council of about 250 members chosen from among the leaders of American science, respectfully recommends to the Senate and to the House of Representatives of the United States that the Kilgore Bill (S. 702) be not passed either in its present form or in any other form containing similar provisions.

The A.P.H.A. representatives on the A.A.A.S. Council are Abel Wolman, Dr. Eng., Chairman of the Executive Board, and Reginald M. Atwater, M.D., Executive Secretary.

Central States

LEONARD C. BATE, M.D., of Stambaugh, Mich., Director of the Iron County Health Department, was placed in charge of the unit in Ontonagon County, effective June 1. The central office of the two counties will be maintained in Stambaugh, with a branch in Ontonagon.

MARY P. CONNOLLY,* Director of Health Education for the Department of Health of Detroit, Mich., has retired after 25 years' service.

CLIFFORD C. CORKILL, M.D.,† resigned as head of the Menominee County Health Department, Menominee,

Mich., effective July 1, to enter private practice.

MADELENE M. DONNELLY, M.D., has been named Director of Health District No. 7, comprising Clare, Gladwin, and Arenac Counties, following the vacancy that occurred with the transfer of HELEN P. LANTING, M.D., M.S.P.H.,† of Gladwin, Mich., to a similar position in the Shiawassee County Health District.

STEPHEN E. GAVIN, M.D., of Fond du Lac, Wisc., has been appointed a member of the Wisconsin State Board of Health for a term expiring in 1950.

RUTH E. GROUT, PH.D.,* Minneapolis, has joined the faculty of the University of Minnesota as associate professor in the Department of Preventive Medicine and Public Health and of the College of Education, as announced by Ruth E. Boynton, M.D., professor in the department. Dr. Grout for the last year has been special consultant in health education, U. S. Office of Education in Washington, prior to which she was Senior Supervisor of Health Education with the Tennessee Valley Authority, Chattanooga, Tenn.

GUNNAR GUNDERSEN, M.D., of La Crosse, Wisc., was recently elected President of the Wisconsin State Board of Health.

FRANK J. HILL, M.D., M.P.H.,† of Bismarck, N. D., who has been Acting State Health Officer for North Dakota for the past 18 months, has been appointed State Health Officer by the North Dakota Public Health Advisory Council for a term of 4 years.

THOMAS F. MANCUSO, M.D., Assistant Surgeon, U. S. Public Health Service, reserve, who has been on assignment to the Michigan Department of Health, has been named to succeed HAROLD T. CASTBERG, M.D.,† Passed

Assistant Surgeon, U. S. Public Health Service, who has been organizing the Oregon State Industrial Hygiene Division. Dr. Castberg has been assigned to the California Bureau of Industrial Health, of which he formerly served as Acting Chief.

MRS. MEREDITH NICHOLSON, JR., of Indianapolis, Ind., has been appointed first full-time Executive Secretary of the Indianapolis Social Hygiene Association, effective July 1. Mrs. Nicholson is a member of the Indianapolis Board of Health and Charities and has long been active in social work in Indianapolis.

REGINALD C. SHERWOOD, PH.D.,† of St. Paul, Minn., Food Chemist, has been appointed by RUSSELL M. WILDER as his Assistant Chief in the civilian food requirements branch of the Food Distribution Administration at the Department of Agriculture in Washington, D. C.

MARY SOULES, M.D., M.P.H.,† who has been Assistant Director of Maternal and Child Hygiene for the North Dakota State Department of Health, Bismarck, N. D., has been appointed Director of that division, effective August 1, in place of ROBERT G. WHITE, M.D., M.P.H.* Dr. White was recently appointed Director of the Burke-Minot-Ward District Health Unit, effective August 1.

I. F. THOMPSON, M.D.,* Commissioner of Health in Racine, Wisc., was recently appointed a member of the Wisconsin State Board of Health and is serving as Vice President of the Board.

Eastern States

LEAH BLAISDELL, R.N.,* has been appointed as Director of the Henry Street Visiting Nurse Service, New York, N. Y., effective July 15. For the last 5 years Miss Blaisdell has served Henry Street as Assistant Director, previous to which time she

* Fellow A.P.H.A.

† Member A.P.H.A.

was for some years Educational Consultant in Public Health Nursing with the New York State Department of Health, Albany.

LEVERETT D. BRISTOL, M.D., DR.P.H.,* of Montclair, N. J., who was named as State Director of Health of New Jersey in July, has declined the appointment. Dr. Bristol is Health Director of the American Telephone and Telegraph Company in New York, N. Y.

GEORGE CAMPANA, M.D., M.P.H., formerly Assistant District State Health Officer in New York, and recently of New Rochelle, N. Y., has been appointed State Epidemiologist and Director of the Division of Preventable Diseases for North Dakota, in Bismarck, N. D. He received his public health training at Johns Hopkins University, and has had public health experience in New York City and State Departments, and in Delaware.

KATHERINE FAVILLE, R.N.,* who since 1937 has been Executive Director of the Henry Street Visiting Nurse Service, New York, N. Y., has resigned, according to an announcement made by the Service in July. Miss Faville is Chairman of the Committee in charge of recruitment of nurses for the National Nursing Council for War Service, New York, N. Y.

GRACE MACLEOD, PH.D., has been named in charge of a special planning committee to carry out the city nutrition program originally set up by the New York Department of Health to disseminate information in the best use of the available food supply in terms of a well balanced diet. The special planning group will be part of the Coördinating Committee sponsoring the program.

RUTH A. PARMELEE, M.D., M.P.H.,† who received her degree in public health recently from the Harvard School of Public Health, Boston, has

sailed for Syria enroute to Greece as a missionary of the American Board of Commissioners for Foreign Missions, Boston. Dr. Parmelee has served in the Near East since 1914.

Southern States

JOHN A. COWAN, M.D., M.S.P.H.,* Health Officer of Sioux City, Iowa, has been appointed Venereal Disease Officer for the Oklahoma State Department of Public Health, succeeding EUGENE A. GILLIS, M.D., M.P.H.,* Passed Assistant Surgeon, U. S. Public Health Service, who has held the position for 4 years on loan from the Public Health Service. Dr. Gillis is being transferred to Austin, Tex.

RICHARD O. C. GREEN, M.D., of Alexandria, La., formerly Director of the Rapides Parish Health Unit, has been named to a similar position with the Webster Parish Health Unit, succeeding EDMOND G. KLAMKE, M.D., M.P.H.,† of Minden.

STEPHEN V. LUDDY, D.D.S., M.P.H.,† who has been director of the Bureau of Dental Hygiene in the West Virginia State Health Department, Charleston, has resigned to accept a position with the Virginia State Board of Health, Richmond. Temporarily he is assigned to the City Health Department, Alexandria, as director of the city school dental health program. Dr. Luddy formerly was Director of the Division of Oral Hygiene in the North Dakota State Health Department.

JOHN E. OFFNER, M.D., of Weston, W. Va., has been appointed to succeed CLIFTON F. McCLINTIC, M.D.,† as State Health Commissioner of West Virginia, a position Dr. McClintic has held since 1941. Dr. Offner has for 10 years been Superintendent of the Weston State Hospital.

* Fellow A.P.H.A.

† Member A.P.H.A.

BRIGADIER GENERAL JAMES STEVENS SIMMONS,† A.U.S., Director of the Division of Preventive Medicine, Office of the Surgeon General, U. S. Army, Washington, D. C., has been appointed a member of the Visiting Committee for the Harvard School of Public Health, Boston, Mass., according to an announcement by the Board of Overseers of Harvard College.

MARTIN B. WOODWARD, M.D., C.P.H.,* Registrar, State Board of Health, Columbia, S. C., has been named as Director of the Bureau of Vital Statistics of West Virginia, succeeding FRANKLIN H. REEDER, M.D., who is in the military service. Dr. Woodward has served as Director of a similar bureau in the South Carolina Health Department for several years past.

Western States

PAUL R. ENSIGN, M.D.,† has resigned as Director of the City and County Health Unit in Boise, to accept a position as Pediatric Consultant of the Division of Maternal and Child Health of the Georgia Department of Public Health.

ALAN L. HART, M.D.,† of Boise, Idaho, Consultant in Tuberculosis for the Idaho State Department of Public Health and the Idaho Tuberculosis Association, has been granted a leave of absence by the State Department to accept a temporary assignment as roentgenologist at the induction center for the armed forces in Seattle.

CLIFFORD KUH, M.D., Dr.P.H.,† has resigned as Director of the California State Bureau of Industrial Health, to join the Permanente Foundation in California.

HOWARD W. LUNDY, Dr.P.H.,* formerly Professor of Bacteriology and Public Health, State College of Washington,

Pullman, Wash., was appointed Health Education Coördinator in charge of the informational section of the Division of Public Health Instruction, Illinois State Department of Public Health, Springfield.

LELAND E. POWERS, M.D.,† Health Officer of Tacoma, Wash., has been appointed Director of the Washington State Department of Health. He succeeds DONALD G. EVANS, M.D.,† of Seattle, who, according to *Northwest Medicine*, will enter private practice.

HUBERT O. SWARTOUT, M.D., Dr.P.H.,† was appointed Health Officer of Los Angeles County, Calif., on June 17. He had been Acting Health Officer.

JOHN W. UNIS, M.D., of Seattle, Wash., has been appointed Medical Supervisor for the Department of Social Security. He succeeds JOHN M. FLUDE, M.D., who resigned to enter private practice in California.

LLOYD E. WEBSTER, of Los Angeles, Calif., has been appointed Director of Health Activities for the Los Angeles County Board of Education.

ROBERT H. WELDING, M.D., of Ellensburg, Wash., has been named Health Officer of Kittitas County.

Hawaii

LEO BERNSTEIN, M.D.,† Passed Assistant Surgeon (R), U. S. Public Health Service, who has been Health Officer on Kauai, has been transferred to the position of Health Officer for the Island of Hawaii in the Territory of Hawaii. His address is care of the Board of Health at Hilo, Hawaii, T. H.

Epidemiology of Epidemic Keratoconjunctivitis

JAMES E. PERKINS, M.D., F.A.P.H.A., ROBERT F. KORNS, M.D.,
F.A.P.H.A., AND ROBERT S. WESTPHAL, M.D.

New York State Department of Health, Albany, N. Y.

IN the summer and fall of 1941 outbreaks of epidemic keratoconjunctivitis were reported from Hawaii and from the West Coast.^{1, 2, 3} In the early part of 1942 cases were first recognized in the East in New York City.^{4, 5, 6} In the latter part of September, 1942, the disease was first recognized in upstate New York in the form of an outbreak in a large manufacturing concern in Schenectady. As the result of a survey of industrial plants conducted by the district state health officers, it was found that cases had occurred earlier that year elsewhere in New York State, the first such outbreak consisting of approximately 35 cases in two related plants in Rochester, N. Y., in July. As the histories in these cases were typical and more than half of the patients developed corneal opacities, there seems little doubt as to the diagnosis. In spite of the large number of people employed in these two Rochester plants, the infection apparently died out of itself without any special control measures being instituted. In Buffalo and

vicinity a number of industrial plants had typical cases develop among their employees at about the same time that cases appeared in Schenectady, and although the aggregate number of cases in this area was in the hundreds, no one plant apparently suffered an incidence comparable with that in the Schenectady plant. Only a few scattered cases were uncovered elsewhere in the state. Since the Schenectady outbreak apparently is the largest epidemic reported thus far in one industrial plant and was studied intensively while in progress, the remainder of this report will deal with that outbreak.

At the request of military authorities exact numbers will not be given. Suffice it to say that the manufacturing concern in question employs many thousands of employees and that the number of cases which have occurred in the plant exceeds by a wide margin the 600 cases estimated by Rieke as having occurred in the Oregon Shipbuilding Corporation Yards.³ The plant covers a large tract of land and is served

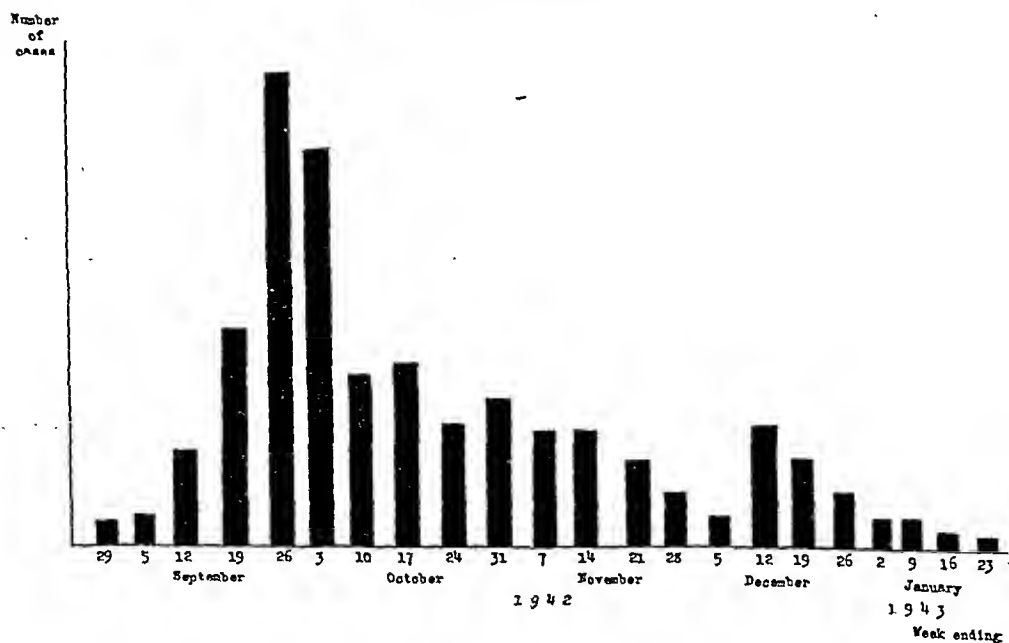

medically by a main dispensary located essentially in its center, together with a branch dispensary in charge of a physician at the east end of the plant. In addition there is a first aid room in the charge of a nurse at a subsidiary plant located elsewhere in the city.

THE DIAGNOSIS AND CLINICAL PICTURE

The cases were typical of those described in the literature^{1, 2, 3} and the diagnosis was confirmed by Drs. Murray Sanders and Alton E. Braley, of the College of Physicians and Surgeons, Columbia University, New York. Furthermore, patients with the disease were demonstrated by Dr. Murray Sanders to have developed specific neutralizing antibodies against the virus previously isolated by him from New York City cases.⁷ Although all gradations of severity were encountered, it was the general impression of visiting physicians who had seen cases

elsewhere in the United States that on the average these cases were more severe than those they had encountered elsewhere. From September 28 to October 23, inclusive, essentially every case reporting to the plant's medical department was studied intensively (comprising several hundred definite cases and referred to from this point on as the "study sample"). Among this group of patients, 56.1 per cent developed the disease in both eyes and 85.5 per cent developed corneal opacities. In those with corneal involvement, the opacities appeared between the 7th and 20th day after onset in 92 per cent. The actual distribution of cases according to appearance of opacities by 7 day periods from date of onset was as follows: 0-6 days, 7.0 per cent; 7-13 days, 65.8 per cent; 14-20 days, 26.3 per cent; 21 days and over, 0.9 per cent. In only 19 per cent had the opacities disappeared by the end of the second month after onset.

Chart 1
Epidemic Keratoconjunctivitis
Schuette's Outbreak
KNOWN CASES BY DATE OF ONSET

CHRONOLOGICAL DEVELOPMENT OF OUTBREAK

As to the chronological development of the outbreak, a study of the number of visits to the eye clinic revealed a definite rise beginning September 10. The distribution of known cases by date of onset is shown in Chart 1. Since the investigation of the outbreak was not begun until September 24, a few cases probably occurred prior to that date which were not seen and are not indicated on the chart. Furthermore, in some cases the date of onset was not determined. However, it is believed the number of such cases was not sufficiently great to affect materially the characteristics of the chart.

It will be noted from Chart 1, that some patients dated the onset of their infection in the last week of August. Cases increased precipitously to a peak in the week ending September 26. The outbreak declined less rapidly than it developed, but ultimately approached the zero line by the week ending January 23, 1943. Only a few scattered cases have occurred since that time. One might ask whether the introduction of new employees (presumably non-immune) into the plant population may not have served to keep the outbreak going. The facts, however, do not support this theory, since study of all the cases with onsets from December 1 through March 13 fails to show any who had been employed at the plant less than 6 months.

The manner of introduction of the infection into the plant could not be ascertained. During the previous spring a number of cases of conjunctivitis had occurred among the employees, but corneal opacities did not develop in these cases nor were the other diagnostic characteristics present. The plant's ophthalmologist stated definitely that clinically the cases which occurred that spring were not the same disease which appeared in the fall. Furthermore, no

neutralizing antibodies were found in serum from one of these patients, 5 months after onset. The number of such cases was so small that the total number of visits to the eye clinic during those months was not appreciably affected. This is in contrast with the marked increase in total visits in the fall because of the appearance of epidemic keratoconjunctivitis.

An intriguing lead was encountered when it was learned that a fairly large corps of employees had been sent to the Hawaiian Islands in March, 1942, to help repair the damage at Pearl Harbor. However, it was found that all but two of the group returned to Schenectady after October 21, 1942; that is, some time after the peak of the epidemic keratoconjunctivitis outbreak had been passed. None of the group had developed epidemic keratoconjunctivitis nor, in fact, were they aware of any cases in Hawaii. The two men who returned prior to October 21 arrived in August and the first week of September, respectively. Although the possibility that the employee returning in August was a passive carrier cannot be definitely refuted, it seems rather absurd to attempt to attribute the outbreak to this man, in view of the presence of the disease earlier that year in New York City and elsewhere in the state, the hiring of many new employees from various parts of the United States, and the transferring of employees back and forth between the Schenectady plant and plants of the concern located elsewhere in the country.

GEOGRAPHICAL DISTRIBUTION OF CASES

The geographical distribution of the cases did not assist in determining the manner of introduction of the infection and direction of spread. A spot map of known cases made on the first day of investigation (September 24) revealed that cases had already been reported from essentially every building

in the plant; and an analysis later by date of onset showed almost simultaneous appearance of the disease in many buildings. Certain buildings, however, suffered attack rates somewhat higher than others. There appeared to be no particular geographical concentration of the buildings with the lower attack rates except that essentially all of the buildings at the east end of the plant had proportionately fewer cases. These buildings are mostly office buildings and are served by the branch dispensary.

TABLE 1

Epidemic Keratoconjunctivitis
Schenectady Outbreak

Attack Rate for Each Sex by Type of Building

Type of Building	Attack Rate Per cent		
	Male	Female	Both Sexes
Entire plant	1.3	0.5	1.1
Selected buildings:			
Heavy manufacturing	2.7	...	2.6
Light manufacturing	1.1	1.1	1.1
Light assembly	0.6	0.4	0.5
Exclusively clerical	0.3	0.2	0.3

In Table 1 buildings have been combined according to whether they represent heavy manufacturing, light manufacturing, light assembly work, or exclusively clerical work, and attack rates have been calculated on the basis of the study sample defined above. It will be noted that employees in the buildings representing heavy manufacturing (manufacture of massive steel structures involving welding, gas cutting, planing, etc.) suffered the highest attack rate, with progressively lower attack rates occurring among those engaged in light manufacturing, light assembly work, and exclusively clerical work.

This table also is of interest from the standpoint of the sex distribution of cases. The great majority of cases occurred among males, but the great majority of the plant population con-

sists of males. However, even on an attack rate basis, it was noted that for the entire plant the males suffered an attack rate over twice that for females. When these sex specific attack rates are broken down according to buildings grouped by type of work, the sex difference essentially disappears and the difference with regard to the entire plant is due chiefly to the fact that few women are employed in the buildings involving heavy manufacturing processes.

OCCUPATION, AND POSSIBLE ROLE OF
FOREIGN BODY IN THE EYE

This brings up the question as to the rôle of foreign bodies in the eye as a predisposing factor in the development of the clinical illness. Determining the existence of such a relationship and distinguishing it from the possible rôle the eye dispensary might have played in dissemination of the infection are very difficult problems. The first symptom of the disease may simulate that of a foreign body and at first the patient may think that he merely has something in his eye. If such a person goes to the eye dispensary because of this sensation and then shortly afterward develops the rest of the symptoms of the disease, he may get the erroneous impression that he acquired his infection at the eye clinic. Even in the case of actual removal of a foreign body from the eye in the dispensary several days before development of the disease, the subsequent appearance of epidemic keratoconjunctivitis might have been due to a predisposing rôle played by the trauma of the foreign body rather than infection of the eye acquired in the clinic during the process of removing the foreign body.

Determining attack rates by occupation is of some assistance in attacking this problem. Using the study sample to calculate attack rates by occupation, the figures indicated in Table 2 are ob-

TABLE 2

*Epidemic Keratoconjunctivitis**Schenectady Outbreak**Incidence according to Type of Work*

<i>Type of Work</i>	<i>Attack Rate Per cent</i>		<i>Type of Work</i>	<i>Attack Rate Per cent</i>	
	<i>Total</i>	<i>No. Visit *</i>		<i>Total</i>	<i>No. Visit *</i>

Testers	1.9	0.7	Clerks	0.4	0.3
Tool and die makers	1.8	1.1	Draftsmen	0.1	...

* i.e., exclusive of those having visited the eye clinic 3-14 days prior to onset of the epidemic keratoconjunctivitis

tained. A striking feature of this table is the high attack rate among dispensary physicians and nurses, indicating the communicable nature of the infection under conditions of intense exposure. Upon studying the attack rates among the other occupations, it would appear that higher attack rates were sustained by employees in occupations more apt to result in eye trauma. However, since this might merely mean more frequent visits to the eye dispensary where infection might be acquired, a parallel row of rates has been calculated in which all cases have been omitted in which there was a history of a visit to the eye dispensary from 3 to 14 days prior to onset. Essentially the same relationships are maintained in this second series of rates. Offhand, this would seem to indicate a relationship to occupation, per se, but as will be discussed later there may be another explanation.

Not indicated in this table is the fact that workers on the night (second and third) shifts had attack rates almost twice as high as those on the day shift. This is explainable by the fact that the night shifts include a relatively greater proportion of workers in occupations

with higher attack rates. Possibly the presence of the infection in a male nurse handling some of the eye cases at night had a bearing on this problem. This individual continued to work during his illness. The total number of cases in persons on the night shifts was not large enough to influence appreciably the occupational distribution of the total group of cases.

Also not indicated in Table 2 was the high attack rate (5 among 11 men, or 45.4 per cent) in volunteer night firemen, whose daytime jobs were various and widely scattered, but who at night congregated at the firehouse and slept in a dormitory. It happens that these sleeping quarters are on the second floor of the main dispensary, but it is not believed that this indicates any causal relationship. It is felt that the high attack rate among these firemen was probably due to their prolonged and intimate contact with each other following the introduction of a case into their midst. No case occurred among the 8 professional firemen on day duty only.

To assist further in the solution of this problem, histories were secured from a series of several hundred em-

* Histories from employees coming to dispensaries because of common cold

† Indicates no visit to eye clinic at the Main Dispensary within 3-14 days prior to onset

ployees reporting consecutively to the dispensaries because of the common cold. This was for the purpose of securing data for the plant population as a whole to be used for comparison with the data secured on the history sheets for the epidemic keratoconjunctivitis cases. This method of sampling the employee population was decided upon when plant officials deemed it impractical to obtain the data by interviewing every one-hundredth person on the pay roll. The sex distribution of these common cold cases (21 per cent females) agreed well with the sex distribution of the plant population as a whole (23 per cent females), and the distribution by buildings also agreed well with the distribution of the employee population as a whole. The investigation of the study group of epidemic keratoconjunctivitis cases preceded in time the survey of workers with the common colds. However, the average daily number of visits to the dispensary for foreign bodies in the eye was essentially the same in each period (219 and 250, respectively). It seems reasonable, therefore, to assume that the data with regard to the cold survey group can be considered representative of the general plant employee popula-

tion for purposes of comparison with the epidemic keratoconjunctivitis study group. Some of these comparisons are given in Table 3.

First, let it be noted from this table that in over half of the cases (51.7 per cent) the patients gave no history of having visited the eye clinic within 14 days prior to onset. It is obvious, therefore, that the eye dispensary was not the principal direct means of dissemination of the infection. A similar observation was made by Rieke in the Oregon cases.³ However, that such dissemination can occur has been demonstrated by Sanders⁶ in his investigation of 80 cases of the disease in New York City in which transmission apparently occurred through an ophthalmologist's office.

From Table 3 it seems clear that work which involved looking at a bright light, or close work with eyestrain, did not predispose to the development of epidemic keratoconjunctivitis, since the per cent of the general employee population engaging in such work was essentially the same or greater than among employees developing epidemic keratoconjunctivitis. The higher per cent among the general employee population giving a history of close

work involving eyestrain is explainable by the greater proportion of clerks and stenographers in this group. When it comes to work likely to result in foreign bodies in the eye and work involving the wearing of goggles, one notes a definitely higher percentage with a history of such work among those who developed the disease, compared with the average employee. When one considers the question of a previous visit to the main dispensary eye clinic, the discrepancy between the two groups is even more pronounced. Even when visits to the eye clinic for conditions other than a foreign body are considered, there is a significant discrepancy.

FOREIGN BODY VERSUS DISSEMINATION
BY EYE DISPENSARY

An association between the acquiring

of foreign bodies in the eye and the development of epidemic keratoconjunctivitis is indicated from Chart 2. In this chart the epidemic keratoconjunctivitis attack rates have been arranged in order according to various buildings, and on the same chart has been plotted the per cent of the workers in each of these buildings who visited the main dispensary eye clinic in July because of a foreign body in the eye (prior to the appearance of epidemic keratoconjunctivitis in the plant). The general correlation is obvious. (In this calculation only buildings with employee populations exceeding 2 per cent of the total employees have been considered, since rates based on smaller numbers would be capricious.)

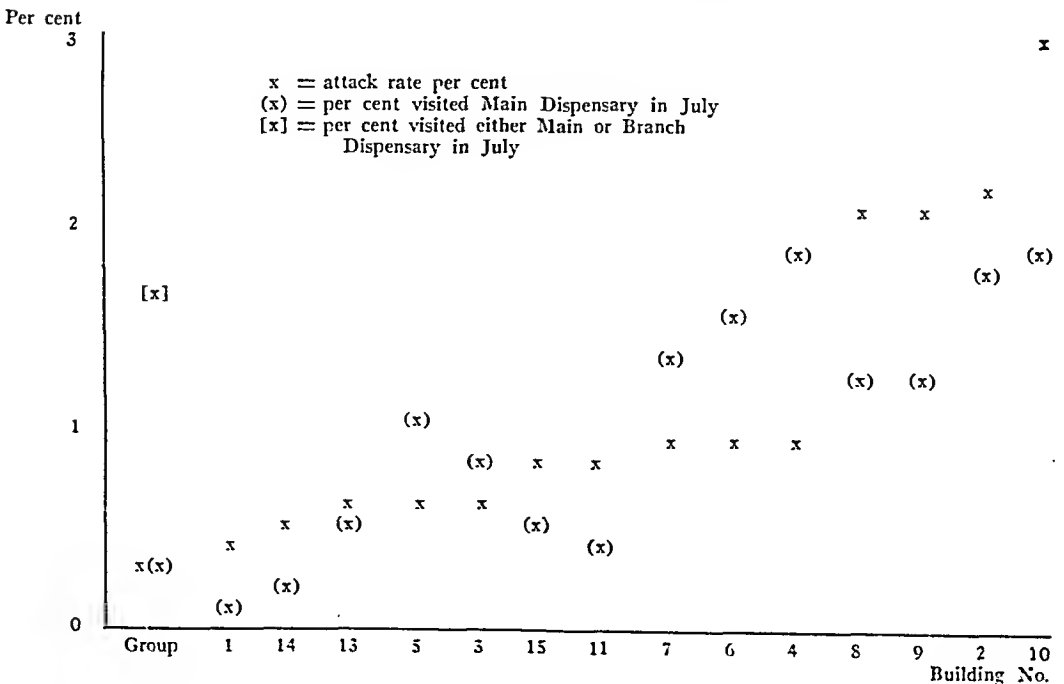

It should be noted that as stated this diagram represents visits to

CHART 2

Epidemic Keratoconjunctivitis

Schenectady Outbreak

Apparent Correlation between Epidemic Keratoconjunctivitis Attack Rate and Visit to Main Dispensary because of Foreign Body in Eye

the eye clinic in the *main* dispensary. The building marked "group" on the diagram is a combination of the buildings in the east end of the plant, where the branch dispensary is located, and represents about one-fifth of the total plant population. If the visits in July to the branch dispensary for foreign bodies in the eye are added to the visits to the main dispensary, 1.7 per cent of the employees in this group of buildings visited a dispensary in July for this reason, as indicated by the cross in brackets, which now obviously throws this group out of line. Although the figures upon which these percentages are based cannot be recorded here, it should be said that this alteration in the per cent of visits for foreign bodies in the eye made by the "group" is highly significant statistically. This finding has at least two possible explanations: first, that the types of foreign bodies acquired by the workers (largely clerical) in this group of buildings did not predispose to the development of the disease to the same extent as foreign bodies acquired elsewhere in the plant; or second, that treatment for a foreign body in the branch dispensary was less likely to result in infection than was similar treatment at the main dispensary. In this connection it was observed that routine technics followed by the branch dispensary appeared much less likely to result in the transmission of infection from one eye case to another, than were the technics followed in the main dispensary. Due to the nature of the records it was impossible to calculate for comparison epidemic keratoconjunctivitis attack rates among those consulting the main versus the branch dispensaries because of foreign bodies in the eye.

In an attempt to differentiate between foreign body as a predisposing factor in itself and acquiring the infection by a visit to the main dispensary

eye clinic, the per cent of epidemic keratoconjunctivitis cases giving a history of having visited the eye clinic within 3 to 14 days prior to onset were calculated according to the week of onset. The thought in so doing was that if the eye clinic was serving as a means of dissemination, the per cent of cases giving a history of having visited the eye clinic within 3 to 14 days prior to onset would increase as the epidemic got under way. The cases for the weeks ending August 29 and September 5 were too small in number to permit reliable percentages. For the weeks ending September 12, 19, 26, and October 3, the per cents giving a history of having visited the eye clinic 3 to 14 days prior to onset were, respectively, 7.2 per cent, 32.8 per cent, 36.3 per cent, and 47.0 per cent.

CONTROL MEASURES AND IMPLICATION AS TO MODE OF SPREAD

Before the intensive investigation of the epidemic was initiated, the plant authorities, suspecting that the eye solutions used in the dispensary might have been at fault, had studied them bacteriologically and had attempted to interrupt possible spread through this means by replacing them with fresh solutions. Starting September 28, a separate room was established in the main dispensary for the handling of epidemic keratoconjunctivitis cases, and all doubtful cases were referred to this room where rigid aseptic technic was used. The importance of applying equally as stringent technic to the routine eye cases, made up largely of foreign bodies, did not become evident until later, and then because of the tremendous patient load being carried by the dispensary, due in turn to the enormous increase in the number of employees, it took a little time to put the recommended changes into complete effect. As a result, procedures which would stand critical scrutiny from a

bacteriological standpoint were not actually instituted for every eye case visiting the dispensary until December 17. These procedures consisted principally of thorough washing of hands routinely between patients, using a separate sterilized dropper for each patient, and frequent sterilization of instruments and solutions.

In view of this date (December 17) it is of interest that although in the 4 calendar weeks from November 29 to December 26, inclusive, 47.9 per cent of the cases gave a history of having visited the eye clinic 3 to 14 days prior to onset, during the next week (December 27 to January 2) this per cent dropped to 33.3 per cent, and from then until the end of the period of observation (March 13) none of the cases gave such a history. As a matter of fact, in each of the few cases occurring subsequent to December 17 in which there was a history of prior visit to the eye clinic, that visit had been made before December 17. Thus there was no evidence that after December 17 the eye clinic could possibly have been responsible for dissemination of the infection, in contrast with earlier data.

SECONDARY CASES IN HOUSEHOLDS

A study was also made of members of the households of patients. All alleged attacks among household members were confirmed or rejected by personal visits to the home. Among those households in which observation was continued for 28 days from onset in the original case, 4.9 per cent of the household members developed the disease. This corresponds roughly to the incidence among the employees, which was 4.1 per cent, as estimated from the study of the common cold sample. Rieke made a similar observation in the Oregon cases. He states: "Also notable was the rather spotty extension of infection to the workmen's families, the

percentage incidence roughly paralleling that among the men."³ In the secondary household cases in the Schenectady outbreak, the great majority of the household secondary cases occurred among adult females, as one might expect, in view of the fact that the great majority of cases in the plant occurred among adult males. Even on an attack rate basis adult females in the households experienced the highest rate; among household members over 15 years of age, females experienced an attack rate of 7.2 per cent compared with 1.1 per cent attack rate among males. As to children in the families, 3.9 per cent of the girls and 3.3 per cent of the boys developed the disease. It was observed that in general the illnesses were milder in the children.

Secondary cases among household members were most likely to have their onsets during the 2nd and 3rd week after onset in the primary case. The attack rates in the 1st, 2nd, 3rd, and 4th weeks after onset in the primary case were 0.17 per cent, 1.2 per cent, 1.4 per cent, and 0.8 per cent, respectively. In one instance a case occurred 32 days after onset in the primary case, the longest interval encountered, and which, of course, might have been the result instead of some unknown extrahousehold exposure.

Several cases among household members were of special interest. In one instance spread continued through one family to another related family. In another family there were 3 secondary cases. In still another the flow of infection seemed reversed; the wife of the plant worker developed the disease after going to a local ophthalmologist for a dacryo-cystitis, and her husband subsequently developed the disease. In a fourth instance, a woman developed the disease, although with no known exposure. However, 4 other members of the family worked at the plant in question.

CASES ELSEWHERE IN THE CITY

As to incidence in the community, no cases appear to have been observed in residents of the city prior to the appearance of cases in the plant. Another large manufacturing plant in the city, employing about one-fourth the number of workers in the first concern, experienced a wave of epidemic keratoconjunctivitis among its employees which, however, was distinctly secondary, chronologically, to the first outbreak. In an attempt to avoid the experience of the first plant, this concern instituted a policy of supposedly rigid exclusion from work of all employees developing the disease until 2 weeks after onset. Despite this policy, their employees suffered an attack rate roughly comparable with that in the first concern.

DISCUSSION

The situation in the last of the households discussed above suggests the existence of carriers, since the woman who developed a typical attack of the disease was not employed in the plant and had no other known exposure to a case, and yet there were 4 members of the household who were workers in the plant. Although none of these workers had any symptoms suggestive of the disease, it seemed possible that they might have brought the infection home. Accordingly, blood specimens from the case and 3 of the family members were collected 6 months after onset in the case and submitted to Dr. Murray Sanders for study. The findings are of considerable interest, since sera from each of the 4 persons showed 1,000 neutralizing doses to the virus isolated by Dr. Sanders. The widespread distribution of cases in the plant as early as September 24, taken in conjunction with the small percentage of the employees suffering clinical attacks of the disease, further suggest that the virus may be readily transmitted from person to person (respiratory?), but that only

a small percentage of those becoming infected develop a clinical attack. Serological studies of atypical cases and household contacts and plant employees who failed to acquire the clinical illness are being made and may throw some light on this problem.

If this conception that clinical cases represent just a fraction of the total number of infected individuals is correct, the question then arises as to what factors predispose to development of the clinical infection. The three usual factors may be considered, namely, variation in virulence of the virus, variation in dosage, and variation in resistance of the host. There is no evidence as to variation in the virulence of the virus. There was a clinical impression that cases became more mild as the outbreak progressed, which would be contrary to the usual experience with repeated passage of a virus. However, it seems more likely that this impression was a false one due to the fact that the outbreak had been under way several weeks before investigation was started, so that among the cases with onset in August or early September, only the more severe cases were still showing acute symptoms when the investigation commenced. There may also have been the factor of a greater tendency later in the outbreak for the milder cases to report to the clinic, in response to publicity and instructions.

As to dosage, the high attack rate among physicians and nurses employed in the dispensary and the high attack rate among adult females in the households of patients would seem to indicate that more intense exposure is more likely to result in development of the clinical disease. In none of the cases developing among household members was there a history of a foreign body during the 2 weeks prior to their onset. This was also true, with one exception, among the physicians and nurses who acquired the disease. The experience

among the volunteer night firemen further indicates the important rôle of intimate contact in spread of the infection.

As to factors influencing resistance in the host, the variation in rate according to occupation, with cases omitted which might possibly have been instances of infection acquired at the eye clinic, suggests offhand that some factor related to occupation might have altered resistance to the virus. One is immediately impressed with the higher attack rates in those occupations in which the eye is more likely to be traumatized, and it would seem reasonable that trauma to the eye might result in reducing resistance to invasion of the virus. That there was a relationship between the likelihood of acquiring ocular foreign bodies and the development of the disease was demonstrated by the correlation by buildings between frequency of reporting to the eye clinic for foreign bodies in July, prior to the outbreak, and the epidemic keratoconjunctivitis attack rates. Also of interest in this connection is the higher percentage of the epidemic keratoconjunctivitis cases giving a history of engaging in work involving the likelihood of developing foreign bodies in the eye, wearing goggles, and of prior visits to the eye clinic, in contrast with the sample of the employee population. At least part of this difference, however, could be due to dissemination of the infection through the eye clinic, and other evidence would seem to indicate that such dissemination in the eye clinic did play a rôle in the spread of the infection among employees. There is the possibility, moreover, that the difference in rates by occupation is merely a reflection of dissemination through the eye clinic, since such transmission would result in an earlier and heavier seeding in the occupational groups reporting more frequently to the eye clinic and thus, in turn, result in

greater spread to fellow workers through contact.

Referring to the cases observed in the industrial plants in Rochester and Buffalo, the routine technics practised in the Rochester plants were very good from an aseptic standpoint, and may have contributed to the infection's dying out so promptly in those plants. As to Buffalo, in a disproportionately large number of the cases scattered among various plants, there was a history of a prior visit to a certain few ophthalmologists' offices, suggesting dissemination of infection through these offices.

SUMMARY

Epidemic keratoconjunctivitis appeared in New York State in 1942, first in New York City and later in scattered areas in upstate New York.

An unusually extensive outbreak, apparently the largest to be reported thus far in a single plant, occurred in a manufacturing concern in Schenectady.

Following a rapid rise in the number of cases in September, the outbreak declined, leveling off to a fairly high incidence which was maintained until particularly rigid aseptic technics were instituted in the eye clinic; subsequently new cases decreased to negligible proportions. Approximately 4 per cent of the employee population was affected with a definite attack of the disease, and approximately the same proportion of household members of patients developed the infection after onset in the primary case.

An occupational selection was demonstrated which seemed correlated with the likelihood of eye trauma, but which may have been a reflection of the rôle played by the eye dispensary in dissemination of the infection.

ACKNOWLEDGMENTS: The authors wish to express their appreciation to Mrs. Hilda Freeman Silverman for the statistical calculations,

Dr. Murray Sanders and Mrs. R. C. Alexander for performing the virus neutralization studies of blood sera, to Dr. Alson E. Braley for assistance in differential diagnosis, to the authorities and employees of the plant in question for their excellent cooperation, to Dr. Karl Habel and Dr. Harry Schweigert of the U. S. Public Health Service, for their assistance, to Dr. E. Kellert, Director of the Schenectady County Laboratory, for his assistance in the collection of blood, provision of laboratory space, and many other courtesies, and to the New York State Department of Health Division of Laboratories and Research for preparation of blood specimens for the virus studies.

A Practical Study of Lauryl Sulfate Tryptose Broth for Detection of the Presence of Coliform Organisms in Water*

MAC H. McCRADY, F.A.P.H.A.

Chief of Laboratories, Quebec Ministry of Health, Montreal, Canada

THE studies, initiated by the Committee on Standard Methods in 1934, of media proposed for detection of the presence of coliform organisms in water, the results of which have been reported at various times (1935,^{1,2} 1937,³ and 1939⁴), were continued during the past two years by conducting a practical test of another medium, lauryl sulfate tryptose broth, proposed by W. L. Mallmann and C. W. Darby.^{5,7}

THE MEDIUM

The composition of the medium tested was the following:

	<i>Grams</i>
Bacto-tryptose	20
Bacto-lactose	5
Potassium phosphate dibasic	2.75
Potassium phosphate monobasic	2.75
Sodium chloride	5
Sodium Lauryl Sulfate (Duponol WA Flakes)	0.1

The ingredients were dissolved in 1 liter of cold distilled water, distributed into tubes and autoclaved at 15 lbs. pressure for 15 minutes. The final pH was approximately 6.8.

In this medium, tryptose was employed, instead of peptone, because of its better productivity and selectivity; and sodium lauryl sulfate was included because of its selective effect, somewhat similar to that of some other surface tension depressants such as oxgall, in inhibiting the multiplication

of certain non-coliform organisms.

Cowles⁶ first proposed the use of sodium lauryl sulfate for this purpose. Mallmann and Darby⁷ employed it in their preliminary work in the form of Duponol W. A. Paste,* a commercial product used as a detergent and wetting agent in the textile and other industries. A similar product, Duponol W. A. Flakes,† containing a somewhat larger proportion of sodium lauryl sulfate, was employed in the present study because of its apparently greater stability.

OUTLINE OF THE WORK

The medium described was distributed, in dehydrated form, through the courtesy of Difco Laboratories, Detroit, Mich., to the following 17 state, provincial, county, city and university laboratories in the United States

* Because of the excessive demands to which all laboratories were subjected following the outbreak of war, the labor involved in conducting this study and in compiling and reporting the results thereof, was divided between Dr. W. L. Mallmann, Chairman of the Standard Methods Committee on Water and Sewage, and the writer. It was arranged that the former should initiate the study, enlist laboratories to collaborate in the study and collect the results secured by them, whereupon these results were to be compiled and reported by the latter in his capacity of Referee for the committee. Accordingly, the original results from the collaborating laboratories were transmitted to the Referee early in the year, and from them was prepared the present report.

† Duponol products are manufactured by E. I. Du Pont de Nemours and Company, Wilmington, Dela.

and Canada, the directors of which agreed to collaborate in the study:

The laboratory procedures specified for the comparative work included, briefly, planting of several portions (usually five 10 ml. and one 1.0 ml. portions) of sample in both lactose broth and lauryl sulfate tryptose broth; upon appearance of gas in these primary media, eosin-methylene-blue agar plates were streaked and colonies appearing on the plates were fished to both lactose broth and lauryl sulfate tryptose broth, and also to agar slants for microscopic examination. An additional transfer from gas positive tubes of one or both primary media to brilliant green bile (2 per cent) was also made by the majority of the collaborating laboratories, and the formation of gas in the bile, after incubation at 37° C. for 48 hours, was recorded.

It will be noticed that the procedures specified included two departures from the usual Standard Methods procedure: the substitution of lauryl sulfate tryptose broth for lactose broth as a primary medium, and also its substitution as a secondary medium in the "completed test."

AGGREGATE RESULTS

Since some of the collaborating labora-

tories made no transfers of primary gas positive tubes to brilliant green bile,

and some made such transfers only from lactose broth, the results will be reported under these headings: (A) with no transfer from primary gas positives; (B) with transfer from lactose broth primary gas positives; (C) with transfer from both lactose broth and lauryl sulfate tryptose broth gas positives. Consequently (B) will include (C), omitting from the latter the results of transfer to brilliant green bile from lauryl sulfate tryptose primary gas positives; and, likewise, (A) will include both (B) and (C), omitting from both of the latter the results of transfer to brilliant green bile.

Table 1 shows the aggregate results, reported by the various collaborating laboratories, from samples that yielded one or more primary gas positives. A large number of other samples were examined but, as they gave no gas positives when planted in the two primary media, are not included in the tabulations.

Table 1-A—A total of 17 laboratories reported the results shown in Table 1-A. It will be observed that, from 605 water samples yielding one or more primary gas positives, 1,873 of 3,415 portions of sample, or 54.8 per

TABLE 1

Primary Medium	No. of Sample Portions Planted	Gas Positives Completely Confirmed Using Secondary								Gas Positive upon Transfer of Primary to Brilliant Green Bile
		Portions Gas Positive		Lactose Broth		L.S.T. Broth		Per cent of Sample Portions		
		No.	Per cent of Sample Portions	No.	Per cent of Sample Portions	No.	Per cent of Sample Portions			
									No.	
<i>A. Aggregate Results of Examination of 605 Water Samples Yielding Primary Gas Positives With No Transfer of Primary Positives to Brilliant Green Bile</i>										
Lactose broth	3,415	1,873	54.8	1,117	32.7	1,142(1)	33.4			
L.S.T. broth	3,415	1,628	47.7	1,222(3)	35.8	1,261	36.9			
<i>B. Aggregate Results from 526 Water Samples Yielding Primary Gas Positives With Transfer of Lactose Broth Primary Positives to Brilliant Green Bile</i>										
Lactose broth	2,996	1,687	56.3	1,025	34.2	1,052(1)	35.1	1,088(2)	36.3	
L.S.T. broth	2,996	1,486	49.6	1,115(3)	37.2	1,150	38.4			
<i>C. Aggregate Results from 318 Water Samples Yielding Primary Gas Positives With Transfer of Lactose Broth and Lauryl Sulfate Tryptose Broth Primary Positives to Brilliant Green Bile</i>										
Lactose broth	1,732	1,016	58.7	540	31.2	527(1)	30.4	579(2)	33.4	
L.S.T. broth	1,732	775	44.7	586(3)	33.8	575	33.2	601(1)	34.7	

Note: The figures in parentheses (which are included in the adjoining totals) represent the number of missing tubes, incomplete results, etc., which were considered positive in order to avoid loss of the remaining data obtained from these particular samples; a study of these data suggests that the error thus introduced is very probably negligible.

cent, planted in lactose broth, gave gas positives; whereas, 1,628 of a like number of sample portions, or 47.7 per cent, planted in L.S.T. (lauryl sulfate tryptose) broth yielded gas positives. When these primary positives were plated on eosin-methylene-blue agar and colonies fished to lactose broth and to L.S.T. broth, and to agar slant for microscopical examination, the 1,873 lactose broth primary positives yielded 1,117 complete confirmations of coliform organisms using secondary lactose broth, and 1,142 complete confirmations using lauryl sulfate tryptose broth. Consequently, the substitution of L.S.T. broth for lactose broth as a secondary medium yielded 25, or slightly over 2 per cent, more complete confirmations.

The use of lauryl sulfate tryptose broth as a primary medium reduced the number of primary gas positives from 1,873 to 1,628, or slightly over 13 per cent, but yielded 1,222 complete confirmations when using lactose broth as a secondary medium, and 1,261 when using L.S.T. broth as a secondary medium.

The number of complete confirmations of coliform organisms (1,117) obtained by the use of the usual procedure, employing L.B. (lactose broth), compares with the numbers secured by the use of L.S.T. broth at various stages of the procedure as follows:

Primary	Secondary	No.	Per cent
L.B.	— L.B.	1,117	100.0
L.B.	— L.S.T.	1,142	102.2
L.S.T.	— L.B.	1,222	109.4
L.S.T.	— L.S.T.	1,261	112.9

Thus the use of L.S.T. broth, as primary and as secondary in the completed test, permitted an increase of 12.9 per cent in the number of complete confirmations compared with the usual procedure using lactose broth in these positions, despite a reduction of 13.1 per cent in the number of primary gas positives that had to be examined when using L.S.T. broth.

It is evident that this series of results indicates an increase in the number of sample portions containing coliforms detected through the use of L.S.T. broth, both as a primary and as

a secondary medium, which, although not very great, is nevertheless significant.

Lauryl sulfate tryptose broth was suggested as a primary medium principally because it gave promise of serving as a presumptive medium in which the formation of gas might be considered a practically sure indication of the presence of coliform organisms. In this respect, however, only 77.5 per cent of the L.S.T. primary gas positives yielded coliforms, even when using L.S.T. broth as a secondary medium, compared with 61.0 per cent of complete confirmations secured from lactose broth primary gas positives using the same secondary medium, and 59.6 per cent using lactose broth as the secondary medium. These relationships are shown below in tabular form:

Pri- mary	Second- ary	Primary Gas Positives	Complete Confirmations	
			No.	Per cent
L.B. —L.B.		1,873	1,117	59.6
L.B. —L.S.T.		1,873	1,142	61.0
L.S.T.—L.B.		1,628	1,222	75.1
L.S.T.—L.S.T.		1,628	1,261	77.5

It is interesting to compare these figures with those obtained in a previous study,³ reported in 1937, of the utility of fuchsin broth as a primary medium, with lactose broth the secondary medium, when a number of laboratories collaborated in the examination of 890 waters from various sources. Of 2,903 primary gas positives in fuchsin broth, 70.5 per cent were completely confirmed, whereas of 4,204 lactose broth primary positives, 50.2 per cent were completely confirmed. The number of complete confirmations from fuchsin broth primary gas positives was 97.06 per cent of that from lactose broth primary gas positives, whereas the present study indicates the number of complete confirmations, using L.S.T. broth as primary and secondary media, was 112.9 per cent of that from lactose

primary gas positives. Obviously, to judge from these figures, L.S.T. broth is the better medium of the two; but, as in the use of fuchsin broth, primary gas positives in L.S.T. broth must also be confirmed.

It has been suggested⁵ that the plating medium, eosin-methylene-blue agar employed in the Standard Methods procedure for the "completed test," inhibits the growth of some coliform organisms; and that, for this reason, gas in primary fermentation tubes constitutes evidence of the presence of coliform organisms more frequently than successful complete confirmation indicates. This contention is indeed probable, but the magnitude of the error thus introduced is problematical. A previous study² showed, by transfer from primary gas positives to various liquid media followed by complete confirmation of gas positives in the latter, that the error of the usual completed test performed on primary lactose broth positives averaged, at least, about 14 per cent, even when employing eosin-methylene-blue agar in the complete confirmation of the liquid confirmatory gas positives. If a practicable plating medium less inhibitive than E.M.B. agar can be found for use in the "completed test," the present procedure of complete confirmation may have to be debited with an additional error; but until the magnitude of the error due to the use of E.M.B. agar is definitively determined, there appears to be no alternative to acceptance of this plating medium in the "completed test."

Finally, the aggregate results shown in Table 1-A indicate that L.S.T. broth could not be employed as a presumptive test of the samples examined without confirmation, but that its use both as primary and secondary medium in the "completed test" permitted about 13 per cent more complete confirmations than did the use of lactose broth, with a reduction of about 13 per cent in the

number of primary gas positives that had to be confirmed.

Table 1-B—Fifteen laboratories included a transfer from primary lactose broth gas positives to brilliant green bile in their examination of 526 water samples. It will be observed that the relationships between the "completed test" results, shown in Table 1-B, secured from the use of lactose broth and lauryl sulfate tryptose broth in the examination of these samples, resemble fairly closely those described in the discussion of the results of Table 1-A.

Use of the "confirmatory test," employing transfer to brilliant green bile from lactose broth primary gas positives and considering formation of gas in the bile to constitute evidence of the presence of coliform organisms, indicated 36.3 per cent of the sample portions planted to contain these organisms. This proportion is slightly higher than the 34.2 per cent of complete confirmations secured by the usual Standard Methods procedure, and the 35.1 per cent by the same procedure using L.S.T. broth instead of lactose broth as the secondary medium. It is slightly lower, however, than the proportion of 37.2 per cent obtained from the use of L.S.T. broth as the primary medium, and that of 38.4 per cent secured by employing L.S.T. broth both as primary and secondary media.

Table 1-C—Eleven laboratories included transfers from both lactose broth and L.S.T. broth primary gas positives to brilliant green bile in their examination of 318 water samples.

The results of this series, given in Table 1-C, show that the proportions of water sample portions in which the presence of coliform organisms was indicated by these two "confirmatory" procedures compared with the complete confirmation procedures as shown above, right.

Evidently the indications of the presence of coliform organisms furnished by

<i>P.i.</i> <i>mary</i>	<i>Second-</i> <i>dary</i>	<i>Gas</i> <i>in</i> <i>B.G.B.</i>	<i>Per cent of</i> <i>Water Sample</i> <i>Portions</i> <i>Positive</i>
L.B.	—L.B.		31.2
L.B.	—L.S.T.		30.4
L.S.T.	—L.B.		33.8
L.S.T.	—L.S.T.		33.2
L.B.		+	33.4
L.S.T.		+	34.7

gas formation in brilliant green bile, following transfer from either lactose broth or L.S.T. broth primary gas positives, were slightly less numerous (33.4 per cent) and slightly more numerous (34.7 per cent), respectively, than those (33.8 per cent) furnished by the complete confirmation of L.S.T. primary positives using lactose broth secondary, which in this series of examinations yielded the best of the "completed test" results.

It may be concluded, therefore, from the aggregate results of Table 1, that L.S.T. broth could not be employed in a presumptive test, without confirmation, of these waters; that the substitution of L.S.T. broth both as primary and secondary media yielded somewhat more frequent complete confirmation of the presence of coliform organisms than the other complete confirmation procedures, and about the same number of indications of the presence of coliforms as that from the use of lactose broth primary followed by the brilliant green bile confirmatory test (gas only); and that the use of L.S.T. primary followed by the brilliant green bile confirmatory test furnished, by a small margin, the greatest number of indications of the presence of coliforms.

RESULTS FROM DIFFERENT TYPES OF WATERS

The data summarized in Table 1 are distributed in Table 2 according to type of water examined: Under each type heading are given three sets of figures corresponding to the A, B, and C

groups of Table 1, the first set showing the results secured when no transfer of primary gas positive to brilliant green bile was made, the second set when such transfer was made from lactose broth primary gas positives, the third set when such transfer was made from both primary media gas positives. The

first set of figures includes the second and third, and the second set includes the third, as in Table 1.

It will be observed in Table 2 that the results secured from the various types of waters present as a rule the same general picture as that furnished by the aggregate results. The L.S.T.

10 samples	L.S.T.	40	55.0	50.0	50.0

broth primary gas positives were usually less numerous than the lactose broth gas positives, 56 to 58 per cent less numerous in the case of unfinished and finished waters, although slightly more numerous in the case of well and spring, miscellaneous, and sea waters.

The proportion of L.S.T. primary gas positives that were shown by the "completed test" (using L.S.T. broth as secondary medium) to contain coliform organisms, varied from about 70 per cent for finished waters to 82 per cent for swimming pool waters, the percentage usually ranging between 75 and 80. Evidently the formation of gas in primary L.S.T. broth could not be considered very sure proof of the presence of coliform organisms.

As a rule there was very little difference between the results of employing lactose broth and L.S.T. broth as secondary media in the "completed test."

The use of L.S.T. broth as both primary and secondary media in the "completed test," however, permitted isolations of coliforms from more sample portions than did the use of lactose broth, as indicated below:

<i>Type of Water</i>	<i>Per cent of Positive Completed Tests Using Usual Standard Method (Lactose Broth)</i>
Raw	105
Unfinished	106
Finished	106
Swimming pools	113
Wells and springs	117
Sea water	125
Miscellaneous	137

These figures do not indicate much advantage, as regards positive complete confirmation, in substitution of L.S.T. broth for lactose broth in the examination of waters from purification plants, but it must be remembered that fewer primary positives had to be confirmed when L.S.T. broth was employed. In the examination of swimming pools,

wells and springs, and other waters, however, this substitution increased the number of positive complete confirmations by 13 to 37 per cent.

The "confirmatory tests," employing transfer from primary gas positives to brilliant green bile, indicated as a rule about the same frequency of presence of coliform organisms as did the best of the "completed tests," with one exception: four (Minnesota, Pennsylvania State College, Quebec, West Virginia) of the six laboratories performing "confirmatory tests" of well and spring waters reported a total of positive "completed tests," using L.S.T. broth primary and secondary, which was about 16 per cent greater than that of "confirmatory tests" with brilliant green bile following lactose broth primary. An interesting feature of the reports from these four laboratories on ground waters was the greater number of primary gas positives in L.S.T. broth (554) compared with that in lactose broth (509). Generally, however, the greatest number of positive indications of the presence of coliforms was secured by the use of L.S.T. broth primary followed by "confirmatory" brilliant green bile, taking formation of gas in the latter to constitute a positive result.

Consequently, the results from the various types of water samples examined confirm in general the conclusions derived from the aggregate results. Furthermore, the separate groups of results reported by the various collaborating laboratories, with few exceptions, also confirm these conclusions.

FINISHED WATERS

Since the use of L.S.T. broth appears to reduce the number of primary gas positives that must be confirmed, particular interest attends its employment in the examination of finished waters, which usually yield an excessive proportion of false lactose broth primary gas positives. Consequently Table 3

is presented, showing the results reported by those laboratories that examined at least a few finished water samples.

Of the six laboratories, listed in Table 3, that reported coliforms in finished waters, three isolated more by the use of the usual Standard Method procedure using lactose broth than by the use of L.S.T. broth primary, whereas the experience of the other three laboratories was the reverse.

These data are too few in number to permit a conclusion regarding the applicability of lauryl sulfate tryptose broth to the examination of finished waters. Much more information is needed to establish whether the medium inhibits coliform organisms that have been subjected to purification processes.

CONCLUSIONS

Seventeen laboratories situated in the United States and Canada have collaborated in a study of the utility of lauryl sulfate tryptose broth for detection of the presence of coliform organisms in water. A total of 605 water samples from which primary gas positives were obtained, was examined, em-

ploying L.S.T. broth as a primary and as a secondary medium for comparison with lactose broth in the Standard Methods "completed test" procedure. Of these samples, 526 were also subjected to the "confirmed test" procedure employing transfer from lactose broth primary gas positives to brilliant green bile; and 318 were examined further by transfer from L.S.T. broth primary gas positives to brilliant green bile.

The results reported by the collaborating laboratories indicated that, in general:

1. A reduction of about 13 per cent in the number of sample portions producing gas in the primary medium resulted when L.S.T. broth was substituted for lactose broth, this reduction being particularly evident in the results from unfinished, finished and swimming pool waters.

2. As coliform organisms were isolated from only 75.1 per cent of L.S.T. broth primary gas positives when using lactose broth secondary, and from 77.5 per cent when using L.S.T. broth secondary in the usual Standard Methods "completed test" procedure, it is evident that L.S.T. broth could not be employed as a presumptive medium, without confirmation, in the examination of these waters.

3. Since the use of L.S.T. broth as both primary and secondary media permitted iso-

lation of coliform organisms from 1,261 sample portions, about 13 per cent more than the 1,171 portions from which isolations were secured when lactose broth was employed, the substitution of the former medium for the latter appeared to be advantageous; but the paucity of data reported on finished waters precludes a definitive conclusion at this time regarding the utility of L.S.T. broth in the examination of this important group of waters.

4. The use of the "confirmed test" (transfer of primary gas positive to brilliant green bile, taking gas in the latter to indicate the presence of coliform organisms) yielded about as many positive results as did any of the "completed tests," whether transfer was made from the lactose broth or the L.S.T. broth primary gas positives. Transfer from the L.S.T. broth, however, resulted in a small increase (3.8 per cent) in the number of positive "confirmed tests" compared with transfer from lactose broth gas positives.

On the whole, the substitution of lauryl sulfate tryptose broth for lactose broth in the Standard Methods procedures promises a reduction in the number of primary gas positives to be

confirmed and an increase in the number of positive indications of the presence of coliform organisms. Consequently further study of the medium by interested laboratories is recommended, particularly with reference to its utility in the examination of finished waters.

WITHIN recent years Cuyahoga County has experienced frequent outbreaks of anterior poliomyelitis. During the period 1925-1940, the median number of resident cases reported annually was 40, and no year was free from the disease. In the lowest year, 1938, only 5 cases were reported and in the highest, 1930, the total reached 170. If incidence higher than the median be taken as the criterion, there have been 8 epidemics within this period.

In 1941 the county suffered its largest epidemic, with 189 reported cases. Of these, 134 were residents of Cleveland and 55 of the remainder of the county which includes 13 smaller cities, 40 villages, and 6 townships. The annual attack rate per 100,000 population was 15.5 for the entire county, 15.3 for Cleveland, and 16.2 for the rest of the county. Provisional figures indicate that incidence for the county was approximately twice as high as that for Ohio (7.0) and for the whole United States (6.8). The local character of the epidemic is evident from the fact that the number of cases reported in Ohio was slightly lower in 1941 than

in 1940. In 1940 the disease was most prevalent in the North Central and Northwestern States; in 1941, in the East South Central and South Atlantic States.¹

The present study is an analysis of records collected at the time of this epidemic and on reëxamination of survivors from 4 to 6 months after attack.

I. DATA COLLECTED DURING EPIDEMIC

A central county register for poliomyelitis was established in July, 1941, and current epidemiological records were obtained by public health nurses. Fortunately, 179, or 95 per cent, of the cases were hospitalized. Of these, 174 were admitted to the Contagious Division of the Cleveland City Hospital and 5 to other hospitals in the area. It was thus possible to verify the diagnosis, check the accuracy of many of the entries on the nurses' schedules, and supplement the health department records.

CLINICAL FINDINGS

Type of disease—The clinical classification of all cases reported during the year is presented in Table 1. A striking feature of poliomyelitis is that the relative frequency of various clinical types may differ considerably from epidemic to epidemic. The high propor-

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

tion of bulbospinal and bulbar cases (31.2 per cent) indicates the severity of the epidemic. Only 17.5 per cent were abortive. This is in sharp contrast to the epidemics of 1931 and 1937 in Cuyahoga County, in which 50 per cent and 40 per cent, respectively, of the cases were abortive.²

TABLE 1

Clinical Classification of Cases of Poliomyelitis, Cuyahoga County, 1941

Type	Number	Per cent
Paralytic (total)	156	82.5
Spinal	97	51.3
Bulbospinal	30	15.9
Bulbar	29	15.3
Abortive	33	17.5
All types	189	100.0

Early signs and symptoms—Fever was the most frequent prodromal symptom, occurring in 70 per cent of both paralytic and abortive cases. Muscle pain, headache, stiff neck or back, vomiting, nausea, and fatigue were the next most frequent in order of occurrence.

The interval elapsing between onset of the disease and appearance of paralysis or muscular weakness was ascertained for 133 of 156 cases. Paralysis appeared most frequently on the third day. By the end of the first week paralysis was noted in 80 per cent of those in whom it was ultimately detected. Probably some of the longer intervals are attributable to error in date of onset or to failure to detect muscular weakness promptly.

Spinal fluid—Results of spinal fluid examinations were available for 174 of the cases. Only 5 individuals (3 per cent) had counts of less than 10 cells per cu. mm. and 12 (7 per cent) had counts of 300 or over. The median cell count was 83. There was little difference between cell counts of paralytic and abortive cases.

Differential spinal fluid cell counts were available for 171 cases. Only 10 cases (6 per cent) had counts in which

more than 50 per cent of cells were polymorphonuclear. In 109 (64 per cent) the mononuclear leukocytes predominated and in 52 (30 per cent) only mononuclear cells were present. Here again there was little difference as between the various types of the disease.

EPIDEMIOLOGY

Chronology—Prior to July, 4 cases had been reported, 2 in January and 2 in April. During the first week of July, 1 case occurred in the city of East Cleveland and another in the village of University Heights about three miles away. No connection was established between these cases. Thereafter the increase was rapid and the epidemic reached its peak during the first week of August.

Characteristically, the rise of the epidemic curve was steeper than its fall. One-quarter of the cases had onset prior to August 3, one-half prior to August 17, and three quarters prior to September 6. That is, the second quarter of the epidemic required only 14 days for development, from August 3 to August 17, while the third quarter required 20 days, from August 17 to September 6. All but 2 cases had their onset before October 16.

Geographical distribution—Cases occurred in practically all parts of the county but the distribution was not uniform. In the northeastern section, where the epidemic ran an earlier course, the attack rate was 24.6 per 100,000 as compared to 12.6 for the remainder of the county. At the outset some factor peculiar to the section, such as contaminated milk supply or other food, was suspected. No evidence of this was obtained as is discussed later.

Age—Acute anterior poliomyelitis is commonly referred to as infantile paralysis. Recent trends in age distribution of individuals attacked, however, together with frequent occurrence of the abortive or non-paralytic type of the

disease, have made the term misleading. Smaller proportions of cases appear to be occurring in the very young. Thus in the New York City epidemic of 1916, 79 per cent of cases were under 5 years of age while in that of 1935 in the same city only 34 per cent of reported cases were in children of this age group.

In Cuyahoga County a similar change has taken place. This is shown in Table 2 where the age distributions of cases in 5 outbreaks of poliomyelitis, in which more than 50 cases were reported, are presented. The contrast between the ages of cases in 1941 and in 1930 is especially striking. The percentage of cases under 5 years of age in 1941 was slightly more than one-third that observed in 1930, but the percentage of cases 15 years and over was almost 6 times greater. As a result the median age of cases in 1941 (10.1 years) was 5 years higher than in 1930.

this epidemic the excess was somewhat higher, 115, or 61 per cent of the cases, occurring in males. The attack rate for males was 18.8 per 100,000 and for females, 12.2.

Study of the percentage distribution of clinical types of disease by sex revealed no significant difference. This is in direct contrast to the findings of Davis, Weber, and Arey⁴ in an epidemic of 196 cases in Charleston County, S. C., in 1940, in which the spinal type of the disease was found to be significantly more frequent in females than in males, while the reverse was true for the bulbar and bulbospinal types.

Males were attacked at somewhat earlier ages, their median age being 9.2 years as compared to 11.5 years for females.

Race—In the present epidemic 9 of the individuals reported were Negroes. The attack rate for the Negro popula-

TABLE 2

Percentage Age Distribution of Cases of Poliomyelitis in Epidemics of 1930, 1933, 1934, 1937, and 1941, Cuyahoga County

Age (Years)	Year				
	1930 (170 Cases)	1933 (63 Cases)	1934 (51 Cases)	1937 (70 Cases)	1941 (189 cases)
Under 5	51.2	28.6	31.4	41.4	19.0
5-9	34.1	41.3	33.3	22.9	30.2
10-14	10.6	27.0	17.6	27.1	27.5
15-19	1.2	3.1	9.8	5.7	12.7
20 and over	2.9	7.9	2.9	10.6
Total	100.0	100.0	100.0	100.0	100.0
Median (years)	4.9	7.6	7.8	6.9	10.1

Despite these changes in age selectivity of the disease, poliomyelitis still attacks individuals under 15 years of age far out of proportion to their representation in the population. *Seventy-seven per cent* of all cases reported in 1941 were in persons of these ages who constitute only *20 per cent* of the population of the county.

Sex—A finding common to most outbreaks of poliomyelitis is that males are attacked more frequently than females. The usual percentages are about 55 per cent and 45 per cent, respectively.³ In

this epidemic the excess was somewhat higher, 115, or 61 per cent of the cases, occurring in males. Of cases among Negroes, 5 were abortive, 2 spinal, 1 bulbospinal, and 1 bulbar.

Multiple cases—The 189 cases of poliomyelitis occurred in 180 different families. There were 2 families with 3 confirmed cases each, and 5 with 2. Nine of these cases were of the spinal type, 3 bulbar, 1 bulbospinal, and 3 abortive. Not all of the 9 subsequent cases can be classified as secondary since, in the 2 households with 3 cases each, 2 cases occurred on the same day, and in 2 other

households the interval was only one day. Since the incubation period of the disease is usually considered to fall within the limits of 5 to 20 days after exposure it is more probable that in these families the cases were simultaneously infected than that one infected the other. In the remaining households the later case may have contracted the disease from the earlier, since the intervals between onsets were, respectively, 5, 10, 11, 12, and 15 days. Of these secondary cases 3 were spinal in type, 1 was bulbar, and 1 abortive.

The household schedules were incomplete as regards number and ages of household associates of the 184 primary cases. The estimated number of associates is 438. Among these there occurred 5 cases at the intervals given above, an attack rate of 1.1 per cent, far in excess of that for the entire year for the general population (15.5 per 100,000 or 0.015 per cent).

In addition to these 5 secondary cases only 1 had a history of probable contact. Two cases occurred in the same apartment house within 14 days of each other. Thus, in common with other urban epidemics of poliomyelitis, this outbreak was characterized in general by a lack of obvious association between frank cases of the disease.

Water supply—Only 3 cases occurred outside the area of the Cleveland distribution system. There is no direct evidence, therefore, either for or against the transmission of the virus by drinking water in this epidemic.

Milk supplies—The source of milk used within 3 weeks prior to onset was given for 145 cases. Of these 1 had used canned milk only. For another, the source was the family cow. The remaining individuals obtained milk from 39 of the 135 authorized dairies of the county. There was not a disproportionately large number of cases among the customers of any of these.

Uncooked fruits and vegetables—Facts

regarding the consumption of uncooked fruits and vegetables were available for 172 cases. Of these only 5 had not used raw fruits and vegetables within 3 weeks prior to onset of disease. The names of the stores at which these articles were purchased were not obtained and it is impossible to tell whether there was a disproportionate number of cases among the customers of any grocer. Because of the wide geographic distribution of the cases this appears unlikely.

Thus, from the foregoing, together with other characteristics of the epidemic, it appears unlikely that the virus was spread by the agency of any fruit, vegetable, milk, or water supply.

Swimming—A precautionary measure taken by health officials during the epidemic was the closing of several swimming pools and beaches within the county. A history of swimming within 3 weeks before onset of symptoms was given by 48 individuals and a history of no swimming by 107. On 34 records no information was given. The proportion of swimmers, for persons of the ages attacked, does not seem to have special significance but the swimming status of the general population is unknown.

Attack rates by economic areas of the county—Information as to economic status of inhabitants of various census tracts of Cuyahoga County was obtained in 1940 by the Real Property Inventory and was made available by Howard Whipple Green. For statistical purposes the county has been divided into economic tenths according to the average rentals of rented houses and equivalent rentals of owned homes in census tracts. Each of these tenths includes approximately 29,000 families, one-tenth of the total families of the county. It was possible, therefore, to distribute the cases of poliomyelitis by economic tenths and to compute the corresponding attack rates.

These rates are presented in Table 3.

With the exception of Economic Tenth 5, which had the highest attack rate, the inhabitants of Economic Tenths 7, 8, 9, and 10 experienced rates consistently higher than the remainder of the county. That is, individuals living in areas of more expensive rentals were attacked by the disease somewhat more frequently than those living in other areas.

lected regarding the possible incrimination of flies as a vector of the virus. All the facts which have been collected, including the rather gradual development of the epidemic, the earlier peak in the northeastern section of the county, and the failure to incriminate any water, milk, or food supply, are consistent with the opinion that the disease was spread chiefly by human carriers and that the

TABLE 3

Attack Rates per 100,000 Population by Economic Tenths; Poliomyelitis, Cuyahoga County, 1941

<i>Economic Tenth</i>	<i>Average Rentals of Rented Homes and Equivalent Rentals of Owned Homes in Census Tract</i>	<i>Cases</i>	<i>Population</i>	<i>Attack Rate</i>
1	\$7.15-\$19.42	14	110,258	12.7
2	19.51- 22.75	9	113,452	7.9
3	22.90- 25.48	16	120,925	13.2
4	25.52- 28.34	14	121,449	11.5
5	28.47- 31.78	37	128,564	28.8
6	31.80- 33.52	13	119,437	10.9
7	33.60- 35.42	22	118,538	18.6
8	35.49- 41.59	23	136,147	16.9
9	42.91- 53.04	21	122,800	17.1
10	54.20-170.54	20	125,680	15.9
Total		189	1,217,250	15.5

This fact is emphasized since the discovery of the virus of poliomyelitis in excreta and in sewage points to the possibility of infection by the gastrointestinal route. Also the isolation of the virus from flies in Cleveland and elsewhere⁵ during the summer of 1941 gave widespread popularity to the idea that the present epidemic was spread by these insects. It would seem that if excreta are a major factor either directly or through the agency of flies, inhabitants of lower economic areas would have experienced higher attack rates. It should be added that no directly pertinent epidemiological data were col-

lected regarding the possible incrimination of flies as a vector of the virus.

Case fatality—There were 16 deaths recorded among the 189 cases, a fatality rate of 8.5 per cent. This was lower than the average case fatality for poliomyelitis in Cuyahoga County during the periods 1925-1930 (11.5) and 1931-1935 (14.2), but slightly higher than that for the period 1936-1940 (6.6).

The fatality rate varied markedly according to sex and age (Table 4). The rate for males (11.3) was nearly 3 times that for females (4.1). The risk of death was greatest for males of 10 years

TABLE 4

Case Fatality Rates (Per cent) by Age and Sex; Poliomyelitis, Cuyahoga County, 1941

<i>Age (Years)</i>	<i>Males</i>			<i>Females</i>			<i>Total</i>		
	<i>Cases</i>	<i>Deaths</i>	<i>Rate</i>	<i>Cases</i>	<i>Deaths</i>	<i>Rate</i>	<i>Cases</i>	<i>Deaths</i>	<i>Rate</i>

TABLE 5

Case Fatality Rates (Per cent) by Sex and Clinical Type of Disease; Poliomyelitis, Cuyahoga County, 1941

Type	Males			Females			Total		
	Cases	Deaths	Rate	Cases	Deaths	Rate	Cases	Deaths	Rate
Spinal	58	39	97
Bulbospinal	21	6	28.6	9	1	11.1	30	7	23.3
Bulbar	17	7	41.2	12	2	16.7	29	9	31.0
Abortive	19	14	33
Total	115	13	11.3	74	3	4.1	189	16	8.5

of age and over and least for females of the same ages.

Deaths occurred among the bulbospinal and bulbar cases only (Table 5). For the bulbar type approximately 1 of every 3 attacked died and for the bulbospinal 1 of every 4. Although the fatality rate for each type was higher for males than for females, the number of cases was too small to make the difference significant.

The fatality rate for cases with onset before the median date was higher than for those of the second half of the epidemic. This is attributable entirely to a marked change in fatality rate in the bulbar type. Of the 13 bulbar cases with onset before the median date 7 died while of the 16 with onset after that date only 2 died.

II. REEXAMINATION OF SURVIVORS, FEBRUARY-MARCH, 1942

In February, 1942, approximately 6 months after the peak of the epidemic, arrangements were made for muscle examinations of the survivors. The purpose was to assess the type and extent

of disabilities and to inform the attending physician of the findings. Each of the survivors who reported at the clinic was given a uniform examination to determine the degree of residual paralysis in the muscles of the legs, arms, abdomen, back, neck, face, speech, and deglutition. The results were recorded on standard muscle examination charts.

From the completed charts it was possible to classify the survivors into one or another of the following groups:

Group I—Individuals in whom no weakness or paralysis in any group of muscles was discovered.

Group II—Individuals whose gait was normal and who appeared to have unimpaired use of all extremities. Careful examination, however, revealed slight weakness in one or more groups of muscles.

Group III—Individuals with severe paralysis of one extremity and/or moderate paralysis of other extremities. These impairments were such that with the aid of braces, crutches, or other supports the patient was able to get around relatively well.

Group IV—Individuals with severe paralysis of two or more extremities. These involvements were such that the patient was not (or would not be) bedridden but, even

TABLE 6

Distribution of Survivors Reexamined According to Original Diagnosis; Poliomyelitis, Cuyahoga County, 1941

Original Diagnosis	Total	Reexamined	Per cent of Each Type Reexamined	Per cent Distribution	
				Total	Reexamined
Spinal	97	84	86.6	56.1	61.3
Bulbospinal	23	15	65.2	13.3	11.0
Bulbar	20	17	85.0	11.5	12.4
Abortive	33	21	63.6	19.1	15.3
Total	173	137	79.2	100.0	100.0

with the use of the proper supports, had (or would have) only limited activity.

Group V—Individuals with such severe paralysis of their extremities that they were bedridden.

Examinations were completed on 137, or 79 per cent, of the 173 survivors. The distribution of survivors according to original diagnosis and number of each type examined is shown in Table 6.

Sufficiently large proportions of individuals who had each type of disease were reexamined so that the findings should be fairly representative of the condition of all survivors. If anything, the results should show a smaller proportion of individuals with minimal or no weakness than if all had been examined; for, from telephone conversations with the survivors who were not examined or with some member of their family, it was determined that none was bedridden and that all were up and about. The excuses for not coming in for examination were that the parents did not want to take the child from school; or they did not think the child needed an examination; or, in the case of several adults, that they did not wish to take time off from work.

Two other individuals, one a previous spinal case and the other an abortive, had died from causes other than poliomyelitis since their discharge from the hospital. The causes of death, as given on the death certificates, were a retroperitoneal sarcoma for the former and a fractured skull for the latter.

Results of examinations—The following is the classification of the 137 re-examined survivors according to extent of paralysis:

		Number	Per cent
Group I	normal	7	5.1
Group II	minimal paralysis	77	56.2
Group III	moderate paralysis	38	27.7
Group IV	severe paralysis; not bedridden	10	7.3
Group V	severe paralysis; bedridden	5	3.7
Total		137	100.0

Thus, 5 per cent of the survivors examined were normal and an additional 56 per cent had practically full use of all extremities and could walk normally and unaided. It was considered that with occasional visits to an orthopedist the slight defects found in the latter group could probably be corrected.

The physical impairments of many of those in Group III could likewise be overcome to a large extent by proper treatment. In 15 of these, in whom the damage was limited to a lower extremity, no artificial aid was needed although all walked with a limp. Another who had minimal paralysis of all extremities walked unaided. In 4 the paralysis was limited to one arm, and 1 of these wore a support; 1 wore a corset for support of paralyzed abdominal muscles, and 2 who were still receiving hospital treatment will walk with the aid of crutches or braces when discharged. The remainder walked with the aid of the following: 7 with braces on one leg, 3 with crutches, 3 with braces and crutches, 1 with a cane, and 1 with shoe correction.

The individuals in groups IV and V (11 per cent) were the more seriously affected survivors of the epidemic. They will probably always be seriously impaired or bedridden.

Condition by original diagnosis—In Table 7 the condition of the survivors at reexamination is related to their original diagnosis.

Although the bulbospinal and bulbar types caused high fatality rates the survivors made good recoveries. Of 15 who survived the bulbospinal type only 1 was bedridden (Group V), 4 were classified in Group III, and 10 had recovered with only minimal weakness (Group II). Among those of Groups II and III there are included 3 who had impairment of muscles of face and deglutition, 1 of muscles of face, speech, and deglutition, 1 of muscles of face and speech, and 1 of facial muscles only. Of 17 who survived the bulbar

Total	5.1	56.2	27.7	7.3	3.7	100.0

type 1 was normal and 16 had only minimal weakness. Although none of these was found to have had spinal paralysis during the acute phase of the illness, upon reëxamination 6 showed weakness of muscles of limbs or trunk only, 9 weakness of these muscles in addition to those of deglutition and speech, and 1 of the muscles of the eye.

The spinal type of the disease, which claimed no fatalities, was responsible for all of the severely paralyzed (Group IV) and 4 of the 5 bedridden.

It is instructive that only 4 of 21 who had abortive attacks were normal (Group I). One was found to have had paralysis of the abdominal muscles for which a corset must be worn, and the remaining 16 individuals were all found to have had minimal impairments of abdominal and various other muscles.

Condition by age—The percentage of recoveries (Groups I and II) was higher in individuals under 20 years of age than in those above this age. Sixty-five per cent of the persons who were under 10 years of age at the time of attack and 66 per cent of those from 10 to 19 years of age recovered with no serious paralysis. Only 31 per

cent of survivors of 20 years of age and over recovered to this extent. Because of the small number of cases this finding and the higher case fatality rate for persons of 20 years of age and over, might separately be regarded as of doubtful significance. Taken together they point to the greater severity of the epidemic among adults.

III. PROBABILITY OF ATTACK WITH RECOVERY, PARALYSIS OR DEATH

Poliomyelitis is the most feared of all epidemic diseases. Parents dread not only the possibility of a fatal outcome but also that their children may be struck suddenly by a disabling paralysis. This fear might be tempered if two facts were emphasized more generally. First, only a small proportion of the population is ever attacked by the disease. In the largest epidemic this country has experienced, that in New York City in 1916, only 2 per 1,000 of the population was attacked. In the 1941 epidemic in Cuyahoga County, the largest in its history, the attack rate was only 15.5 per 100,000, or 0.15 per 1,000. Second, fatal or severely crippling attacks occur very infrequently. Even in the younger age

TABLE 8

Chances per 100,000 Population of an Individual Having an Attack of Poliomyelitis and That the Sequel 4 to 6 Months Later Would Be (a) Minimal or No Paralysis, (b) Moderate Paralysis, (c) Severe Paralysis, (d) Death
Cuyahoga County, 1941

Age (Years)	Minimal or No Paralysis (Groups I & II)	Moderate Paralysis (Group III)	Severe Paralysis (Groups IV & V)	Death (Group VI)	Total
Under 10	38.0	15.3	3.3	5.3	61.9
10-19	23.4	8.0	3.0	3.5	37.9
20 and over	0.6	0.8	0.6	0.3	2.3
Total	9.0	3.8	1.3	1.4	15.5

groups the risks are much smaller than is generally appreciated. The findings of this epidemic may be used to illustrate this point.

In a preceding section, 137 survivors have been classified into five groups according to their condition at reexamination from 4 to 6 months after onset. Thirty-six individuals who did not report for reexamination may be distributed, on the basis of their hospital discharge records and of other facts which have been learned, into these groups as follows: group II, 25; group III, 8; group IV, 1; and dead 2. The status of all who were attacked in this epidemic can therefore be estimated with a fair degree of accuracy as follows:

Groups I and II (normal or minimal paralysis) 109, or 57.7 per cent; group III (moderate paralysis) 46, or 24.4 per cent; group IV (severe paralysis; not bedridden) 11, or 5.8 per cent; group V (bedridden) 5, or 2.6 per cent; and group VI (dead) 18, or 9.5 per cent.

By distributing the above figures by age and relating them to the populations in the various age groups, it is possible to determine the probability of an individual having an attack of poliomyelitis that within 6 months after onset would result in (a) no or minimal paralysis, (b) moderate paralysis, (c) severe paralysis, or (d) death.

These probabilities in terms of chances per 100,000 population are presented in Table 8.

In the age group most affected by the disease (under 10 years of age) the chances of an attack in which the sequel would be minimal or no paralysis was 1 in 2,600; moderate paralysis 1 in 6,500; severe paralysis 1 in 30,000; and death 1 in 19,000. With advancing age these probabilities decreased greatly. For those in the age group 20 years and over they were for minimal or no paralysis 1 in 166,000; moderate paralysis 1 in 125,000; severe paralysis 1 in 166,000; and death 1 in 333,000. It should be realized that these probabilities are approximate only and will vary somewhat from epidemic to epidemic.

A Food-Borne Streptococcus Outbreak

V. A. GETTING, M.D., DR.P.H., F.A.P.H.A., S. M. WHEELER,
M.D., F.A.P.H.A., AND GEORGE E. FOLEY

*Commissioner of Public Health, Massachusetts Department of Public Health;
Department of Preventive Medicine and Epidemiology, Harvard Medical
School and School of Public Health; and House of Good
Samaritan, Boston, Mass.*

IN July, 1941, there occurred in a rural town* in eastern Massachusetts, an unusual outbreak of scarlet fever. On July 29, 2 children in a household engaged in milk production were diagnosed as cases of scarlet fever. Since there had been no scarlet fever in this community for several months and since the children had not been out of town, and the only affair attended by them was a church lunch on July 27, the source of the infection was undetermined, and they were removed to an isolation hospital. On the following day, July 30, 5 more cases were reported from a neighboring city and all of them had attended the same church reunion in this town on July 27. It was at once obvious that something unusual had occurred at the Sunday meeting and an investigation was immediately started.

ANALYSIS OF CASES

The church reunion, an annual affair, was attended by an estimated 200 people from the town, from many other municipalities in Massachusetts, and from several other states. The exact number could not be ascertained, as only about 100 registered; many did not arrive until after church services, and not all who attended the services remained for the refreshments. The names of persons attending were obtained principally from the minister's

family and from the ladies who served the refreshments. The investigation was divided into two portions. The first part was performed in the town and the neighboring municipalities by the personnel of the Division of Communicable Diseases of the Massachusetts Department of Public Health. The second portion of the investigation, in distant towns, was performed by other departmental personnel, by local health departments, and by other state health departments. Histories were obtained on all persons who could be located from the list of those present at the affair and on others who became involved in the outbreak by eating the left-over refreshments. In all, 182 case records were obtained; 144 of these attended the Sunday meeting and the remaining 38 did not attend. Of the 144 who attended, 82 were ill, an attack rate of 56.9 per cent. Of those not attending, 20 were ill, an attack rate of 52.6 per cent. Of the total 182 investigated, 102 were ill, an overall attack rate of 56.0 per cent.

The sex of 172 people was known; 99, or 57.5 per cent, were females. Of the 102 patients, 63, or 61.7 per cent, were females; there being no significant statistical difference in the attack rates of the two sexes. Similarly, there was no statistical difference in the attack rates in the different age groups, particularly when the small number of cases in each group is considered.

* U. S. Census—1940—2,275.

Of the 102 patients, 24 developed frank scarlet fever (Table 2), 56 sore throats, 7 diarrhea, 4 vomiting, 3 nausea, and 8 miscellaneous complaints. These groups are mutually exclusive and the patient is listed in each category according to the most severe complaint taken in this order. Eighty of the patients developed infection with the streptococcus, as well as toxemia, as manifested by the frank scarlet fever and the sore throats. Gastroenteric symptoms were predominant among these patients, suggesting the presence of an enterotoxigenic substance.

sisted of coffee and cream, a variety of home-made cakes contributed by the ladies of the church, and ground ham sandwiches. Drinking water was served to only a few individuals and came from the private supply of a nearby home. Some of those drinking the water were ill and some were not; however, no one was found to be ill who had drunk only the water and had nothing to eat. Moreover, there was no illness in the home where the water was obtained.

The investigation revealed (Table 3) that all persons who were ill, with one exception, had eaten either ham sand-

Total	39	63	102	99.8

* These groups are mutually exclusive

Although the age distribution for the two groups as a whole was the same, 16 cases of scarlet fever occurred under 20 years of age and 8 cases occurred in patients 20 or over. Among the sore throat patients, however, only 6 were under 20, whereas 50 were 20 years of age or over. This distribution is explained by the lack of immunity to the erythrogenic toxin of the streptococcus in the younger age group, and is in accord with the usual experience in other streptococcus outbreaks.

The food served after the service con-

wiches or ground ham. Since only 30 per cent of those ill had drunk the coffee, and only 35 per cent had eaten of about 20 home-made cakes, there was no doubt that the illness was correlated with the ham. However, not all persons who had eaten the ham sandwiches were ill. The attack rate among those who ate the sandwiches was 72 per cent.

Of the 140 persons who ate the ham, 4 ate it immediately after it was cooked on Friday night, July 25, and none of these became ill. One hundred and

* Only one case did not eat the ham; she was a contact of the case which was responsible for the contamination of the food.

sixteen ate ham sandwiches at the meeting about 36 hours later, and 82 of these became ill; an attack rate of 70.6 per cent. Fourteen others ate the left-over sandwiches brought home from the meeting; 13 of these became ill, an attack rate of 92.8 per cent. Six other individuals ate some of the ground ham, which had been left over from making the sandwiches; this ham was eaten late Sunday or on Monday, July 28, either as fried ham patties or as ham sandwiches. All of these individuals became ill; giving an attack rate of 100 per cent. There is, thus, definite evidence that the attack rate increased with the passage of time and it may be assumed the toxicity of the ham increased correspondingly.

PREPARATION OF THE HAM

The bread used in the sandwiches consisted of about twenty-five loaves of sliced white bread wrapped in wax paper. The other ingredient of the sandwiches was a commercial mayonnaise which was spread on the bread at the time that the sandwiches were made. Since some of the persons who became ill ate only the ham, the other ingredients of the ham sandwiches are automatically eliminated as possible sources of infection. The ground ham consisted of meat derived from two separate 18 to 20 lb. smoked hams, which were purchased from a local meat packing establishment which had been processing a high grade of hams and bacon for over 93 years.

These hams had been purchased by the local processing house from a large

concern in Boston, their usual source of meat, and were part of a 300 lb. shipment. These hams had been cured in St. Louis and were shipped from Boston in covered barrels to the local concern, where they were kept in a frozen state for about 1 week, then thawed and hung in the smokehouse for 30 hours. Hickory and walnut wood were used for the production of the smoke. At the end of the smoking time, the hams were removed and hung to cool for 2 hours and then sold to the church committee which had ordered them on July 25. One ham was taken by Mrs. A. and the second by Mrs. B. There was no illness among other customers who purchased products from this concern.

These two ladies had cooked hams for the annual church reunions for about 8 years. Upon receiving the ham, Mrs. B. cut it into halves and placed each piece in a covered pan with enough water to cover the meat. The pans were placed over a bottled gas flame and the water was kept boiling from 9:30 a.m. to 3:30 p.m. on Friday. The ham was then removed from the water and the latter thrown away. The cooking utensils were covered aluminum kettles. When the ham was taken from the cooking vessels, it fell off the bones and was exceedingly tender. It was boned by Mrs. B. and placed in an earthenware vessel to cool and then put into a mechanical refrigerator over night. At about 10 a.m. on Saturday, July 26, it was ground on a household meat grinder which had not been used for at least a week previously and the

ground meat was replaced in the same earthenware vessels, covered with oiled paper and placed in the refrigerator. That Saturday noon, Mrs. B. made two sandwiches for herself and her husband. Mrs. C., daughter-in-law of Mrs. B., and her husband, also ate some of the ham Friday night. At the church gathering on Sunday, both Mr. and Mrs. B. ate ham sandwiches and became ill with nausea and vomiting 3 hours later.

Mrs. A. who received the second ham placed the entire ham in an "Army Cannon Boiler" with a cover. She placed this boiler over an asbestos pad which was placed over the bottled gas flame. The water which covered the ham was brought to a boil and then the gas flame was turned down so that the water simmered. The ham was started to cook at 8:15 a.m. on Friday and kept at a simmering temperature to 12:30 p.m., when the flame was turned off. Mrs. A. was able to pull a spoon-like bone out of the large end of the ham and considered this a sufficient test to determine that the ham was properly cooked. Mr. A. had cut off a slice of ham about as large as an ordinary slice of bread and about $\frac{1}{4}$ inch thick and made a sandwich which he ate for his supper Friday night. He also attended the church gathering on Sunday and ate a ham sandwich and had some coffee, but was not sick.

After the ham was cooked by Mrs. A., she was visited by her daughter, Mrs. D., and her two grandchildren, age 4 and 5. Mrs. A. served her three visitors with a piece of ham, each receiving a slice of sufficient breadth to fit about $\frac{1}{2}$ slice of bread and about $\frac{1}{4}$ inch in thickness. This slicing of the ham took place between 7 and 8 p.m. on Friday night. Neither Mrs. D. nor either of her two children was ill; and they did not attend the church nor did they eat the ground ham. The ham was left in the water all night and

was removed at 7:30 on Saturday morning. It was deboned and ground by her and her husband in a household grinder. The ground meat was placed in two earthenware bowls and taken to the church at about 2:00 p.m. on Saturday.

The two hams, cooked and ground by Mrs. A. and Mrs. B., were brought to the church on Saturday, where a distinct difference was noted between the meat from the two hams. The ground ham cooked by Mrs. A. was lighter in color and very moist; the ladies decided to mix this light, moist meat with the comparatively dry and dark meat of the ham cooked by Mrs. B. This mixing was done on each individual sandwich and not in one large bowl. A commercial salad dressing was applied to the bread at the time the sandwiches were made.

After the sandwiches were prepared by the church ladies, they were carefully wrapped in wax paper and placed in a large metal boiler which was left standing in a room in the basement of the church. On Sunday after the church service, these sandwiches and the other refreshments were served on the lawn outside the church. For approximately twenty-four hours, the ham sandwiches were at room temperature on July 26 to July 27. The maximum and minimum temperatures on these days, as recorded by the U. S. Weather Bureau for the neighboring town of Concord, were 89° and 64° on July 26 and 86° and 57° on July 27, 1941.

Mrs. A., who had prepared one of the hams, was perfectly well until Sunday, when she felt ill and as soon as the church services were over, she went home without staying for refreshments. Upon reaching home, she vomited profusely and developed diarrhea. On Monday, July 28, she awoke to find herself covered with a very red rash, which was diagnosed as a frank case of scarlet fever.

Some of the ground ham prepared by Mrs. A. was left over when the sandwiches were made, and a pound of this was sold to Mrs. McD.; this ground ham had not been mixed with the commercial dressing nor with the ham prepared by Mrs. B. Mrs. McD. had not eaten any of the ham sandwiches while they were being prepared nor at the church gathering. After the church service, Mr. and Mrs. McD. returned home, fried four ham patties, using Mrs. A.'s ground ham mixed with cracker crumbs, egg and onion. These were broiled lightly for Sunday lunch. About three hours later, both became extremely ill with nausea, vomiting and diarrhea.

Mrs. S., another woman who helped to prepare the sandwiches, purchased a half pound of ham cooked by Mrs. B. and ate it Saturday night. She also ate some of the sandwiches during the church gathering on Sunday. On Tuesday she developed an extremely sore throat. Mrs. T., however, who had also purchased some of the ham prepared by Mrs. B., ate the ham Saturday night, but did not eat any sandwiches at the church gathering and was not ill.

SOURCE OF INFECTION OF THE HAM

The evidence, as noted, indicates that Mrs. A. was in the early stage of scarlet fever at the time she handled the ham which she prepared. On Friday, about 7 hours after the flame was turned off under the boiler containing the ham immersed in the water, she removed it and cut several slices from it to feed her visitors; and thereafter replaced the ham in the water. Since only the ham which she prepared was responsible for the outbreak, it is assumed that she infected the meat, either directly by her respiratory discharges or indirectly by her hands which had become soiled by the respiratory discharges. The warm media (ham still in water overnight) incubated the streptococcus

for about 12 hours and permitted the formation of the enterotoxigenic substance. Persons who ate the ham while preparing the sandwiches became ill, but not so severely nor with such a high attack rate as those who ate the ham after it was left at room temperature for another 24 hours, thereby permitting further growth of the hemolytic streptococcus and further elaboration of the enterotoxigenic substance.

Cultures were taken from Mrs. A.'s throat, from some of the ham prepared by Mrs. A. and purchased by Mrs. McD., and from the throats of 14 patients. The cultures of 9 of the patients, of Mrs. A., and of the ham were positive for hemolytic streptococci.

The hemolytic streptococci isolated from all these sources were identified as Lancefield Group A, Griffith Type 2. Since ham was the original vehicle of infection, the hemolytic streptococci were cultured in sterile, ground ham in an attempt to demonstrate the production of enterotoxigenic substances. Sterile filtrates of such cultures contained substances which were enterotoxigenic when injected intravenously in kittens, while filtrates of uninoculated ham were consistently negative. Similarly, toxic filtrates could be prepared from ground ham and other tissue media inoculated with various bacteria. Comparative studies with erythrogenic toxins prepared from the same strains indicated that the enterotoxigenic substance was distinct from erythrogenic toxin. Non-bacterial agents such as trypsin, papain, lactic acid, and sodium hydroxide also produced toxic substances in tissue media.

The toxic substance in filtrates of such cultures was dialyzable and could be precipitated with alcohol. The active fractions and whole filtrates were heat stable and resisted a relatively wide range of pH values. Biuret, Millon, and Molisch tests with the fractions and whole filtrates were positive.

Despite the similarity of symptoms produced in kittens, the substances in filtrates of tissue cultures were distinct from staphylococcus enterotoxin. Staphylococcus enterotoxin could be produced in media such as casein hydrolysate which contained no tissue proteins. Cultivation of the hemolytic streptococci in such media did not yield a toxic filtrate. The production of staphylococcus enterotoxin is not inhibited by anaerobic conditions, whereas anaerobic incubation of the tissue media prevented the production of toxic filtrates. Digestion with proteolytic enzymes destroyed the toxicity of tissue filtrates but did not affect staphylococcus enterotoxin. Oral administration of the staphylococcus enterotoxin and the ham filtrate to kittens revealed that only the former produced a reaction, per os.

Some data were obtained which suggest that the proteins in the tissue media were split into toxic amines by the action of enzymes associated with bacterial metabolism. A detailed report of these bacteriological studies is to be published elsewhere.¹⁶

DISCUSSION

Food-borne diseases can be divided into two main divisions: (1) food infection, when the etiological agent is a living organism and the symptoms are the manifestation of the reaction of the host to the action of the infecting organism, and (2) food poisoning where the causative agent is a noxious substance which in itself is responsible for the characteristic clinical sequence. The etiological agent of food infection may be a virus, bacterium, protozoan, or helminth. Food poisoning on the other hand may be divided into two groups: (1) endogenous poisons, which are usually present in the food, and (2) exogenous poisons which are not an integral part of the food but are present as an addition to the food. These

exogenous poisons may be organic substances, such as the exotoxin of the *Clostridium botulinum*, or an inorganic compound such as sodium fluoride.

In this outbreak, gastrointestinal symptoms were outstanding in prevalence. Dick states that the first symptom of scarlet fever is a sore throat which is followed in a few hours to a few days by the sudden onset of toxic symptoms, almost always with nausea and vomiting, and sometimes diarrhea. Stimson speaks of a triad of fever, sore throat, and vomiting, as characteristic of the onset of scarlet fever. However, an analysis of 50 consecutive cases of scarlet fever treated at Belmont Isolation Hospital, in Worcester, Mass., revealed that only 20 cases (40 per cent) experienced nausea and vomiting and only 1 case developed diarrhea. In an analysis of an additional 50 consecutive cases of scarlet fever prior to hospitalization in the city of Worcester, it was found that only 12 cases (24 per cent) developed nausea and vomiting and 2 cases experienced diarrhea. The majority of these cases were due to Lancefield Group A, Griffith Type 2 streptococcus. It would seem, therefore, that scarlet fever is not as frequently characterized by gastrointestinal symptoms as reported by some authors. Even if nausea and vomiting are accepted as characteristic of scarlet fever, these symptoms were unusually prevalent in this outbreak. Nearly all of the persons with scarlet fever and septic sore throat were afflicted with nausea, vomiting, and diarrhea; and in many instances severe gastroenteritis occurred without any symptoms of sepsis or toxemia due to the erythrogenic toxin. The literature of food-borne outbreaks of scarlet fever and septic sore throat does not emphasize, and in some instances does not even mention, the occurrence of gastrointestinal symptoms. Many of these outbreaks, however, were transmitted

by milk. It is possible that ham provides a medium which is more favorable for the production of the enterotoxin substance as observed in this outbreak and in the laboratory procedures described.

SUMMARY

A ham-borne outbreak involved 24 cases of scarlet fever, 56 cases of septic sore throat, 7 of diarrhea, 4 of vomiting, 3 of nausea, and 8 with miscellaneous complaints as herewith reported. One of the hams was cooked by a woman who herself was in the early preëruptive stage of scarlet fever. Gastrointestinal symptoms were predominant. Laboratory analysis revealed Lancefield Group A, Griffith Type 2, hemolytic streptococci from the ground ham, from the throat of the food handler, and from the throats of 9 cases. The production of an enterotoxin substance from a ham substrate is discussed.

Illness Caused by Cadmium

JOSEPH J. SCHIFTNER AND HENRY MAHLER

Bureau of Food and Drugs, Department of Health, New York, N. Y.

OUTBREAKS of food poisoning attributed to ingestion of food contaminated with cadmium have been reported by Frant and Kleeman,¹ Cangelosi,² and the National Institute of Health.³ These foods were found to be acid in nature and were made or kept in cadmium plated utensils with a resultant solution of the cadmium by the acid food.

Recent investigations by the Department of Health of the City of New York indicate that food need not be in direct contact with cadmium plated utensils to become contaminated and cause food poisoning. Refrigerator evaporators, broiler grids, and other utensils have been cadmium plated and are more widely distributed than heretofore suspected. The following two incidents illustrate some of the recent findings in regard to such equipment:

1. On August 11, 1942, a reported food poisoning outbreak involving 3 members of a family was investigated. Severe vomiting, the only symptom, occurred within 1 hour after the meal eaten in common (supper). Recovery occurred in all cases within 3 hours. Lemonade was served at this meal; none was available for examination, but the other foods eaten in common were negative upon chemical and bacteriological examination. Lemonade was prepared in a glass pitcher, and cooled by the addition of ice cubes. The ice cube trays in the refrigerator were found to be made of aluminum.

2. On August 22, 1942, a food poisoning outbreak involving 4 members of a family was investigated.

Severe vomiting occurred $\frac{1}{2}$ hour after all 4 had consumed root beer to which ice cubes had been added. The root beer was the only food taken in common. No root beer was available for examination. Duration of illness was short with rapid recovery. A chemical poisoning was indicated. Investigation revealed that the ice cubes had been made in a defective refrigerator with a sulfur dioxide leak. A sample of ice cubes contained 769 p.p.m. of cadmium. The ice cube trays were made of aluminum.

Thus in the above two groups of food poisonings we had a reasonable suspicion in the first and a definite indication in the second that cadmium was involved, without any evidence of the preparation of food in a cadmium plated utensil. Subsequent investigation revealed that in the first group, cadmium flakes had dropped into the ice cube trays from the evaporator unit which was cadmium plated and was scaling. The investigation of the second group revealed that the sulfur dioxide refrigerant leaked and caused the refrigerator to defrost. The evaporator was cadmium plated. The moisture on the evaporator dissolved the sulfur dioxide, and the resultant acid, reacting with the cadmium on the evaporator, dissolved some of it. The acid solution of cadmium dripped into the ice cube trays, accounting for the presence of cadmium in the ice cubes. These incidents show that the cadmium plated vessels need not be in direct contact with food to be dangerous and to produce illness.

The refrigerators in both of these

cases were made by the same manufacturer. The evaporators were made of steel and had been originally plated with tin. During the guarantee period, the evaporators became rusted and were removed and sent to several platers within this city, with the specific instructions that they be cadmium plated. This manufacturer's service representative also advised several other refrigerator service men and dealers where such plating could be done satisfactorily.

The records of one electroplater revealed that at least 3,000 evaporators had been plated with cadmium for this manufacturer between 1937 and 1939. Cadmium plating had been done for many refrigerator dealers outside of New York City. The investigation led from one electroplater to another. Their records showed that cadmium plating had been done for refrigerator service men, apartment house owners, realty management companies, and private citizens, on refrigerator evaporators, refrigerator grids or shelves, broiler grids used in gas ranges, and various other utensils which do not normally come in direct contact with food. In two specific instances servicemen had asked for tinplating and got cadmium instead. The plating industry had been notified and advised previously by the Department of Health that the use of cadmium is dangerous and that the metal should not be used on food utensils and equipment.

The extent to which cadmium is used as a plating material makes a field test for cadmium a valuable aid. An acid field test is available, but was found to be unreliable. This test consists of placing a drop of dilute hydrochloric or acetic acid on a surface suspected of being cadmium plated, and adding a drop of sodium sulfide. This forms a canary yellow color if cadmium is present. While this test is useful as a screening method to distinguish be-

tween clean aluminum and cadmium plated surfaces, on surfaces such as evaporator units, which are often corroded, this test is of doubtful value because of the presence of interfering metals, particularly, tin, iron, nickel, and silver.

Goldstone⁵ devised a method which is performed easily in the field and which eliminates these interferences. This method is a refinement and adaptation of the laboratory method proposed by Coleman.⁶

It requires the following reagents:

1. *Ammonia—Sodium Nitrate Reagent*
200 ml. of ammonia water (28 per cent)
plus 100 gm. of sodium nitrate diluted
with water to 1 liter volume
2. *Sodium Sulfide Reagent*
100 gm. of sodium sulfide diluted with water
to 1 liter volume
3. *Potassium Cyanide Reagent*
100 gm. of potassium cyanide diluted with
water to 1 liter volume.

The test is performed as follows:

To a small pinch of the metal scrapings in a test tube, add 3 ml. of the ammonia-sodium nitrate reagent; bring the mixture to a boil over a flame and allow to stand for a minute or two. Pour the clear supernatant liquid into another test tube, add 1 ml. of the cyanide reagent and, after shaking, add 1 drop of sodium sulfide reagent. This produces a canary yellow precipitate if cadmium is present. The metals, iron, tin, antimony, arsenic, silver, copper, nickel, chromium, zinc, and aluminum do not interfere. In the case of zinc or aluminum, a whitish gray precipitate is formed which is readily distinguishable from the canary yellow color of cadmium sulfide. If cadmium is present in addition to any of these metals, it is instantly detected. The only metals which do interfere are lead and mercury, but these are rarely, if ever, used as plating metals under these conditions.

With the aid of this field test, a survey was made of 20 apartment houses which were equipped with suspected

refrigerators. Scrapings were taken from 104 evaporators in refrigerators in use in these apartment houses. These were tested in the field. It was revealed that 25 per cent of the number of refrigerators tested had cadmium plated parts. Samples of scrapings from 26 mechanical refrigerators where the field test indicated cadmium, were obtained and were analyzed in the chemical laboratory of the Bureau of Food and Drugs. The findings of the field test were confirmed in all cases. Control samples were also taken. The survey was extended to refrigerator repair shops, and second-hand refrigerator dealers. Here, too, cadmium plated evaporators were found. One cadmium plated evaporator was found which had been sent to New York City from a dealer who had a surplus stock in Chicago.

Conferences were held with the manufacturer of the refrigerator involved, with realty management companies, and apartment house operators using second-hand or repaired refrigerators, to acquaint them with the problem. Representatives of these companies were taught how to perform the field test, and the companies were charged with the responsibility of checking their refrigerators for cadmium plating and for rendering them safe by deplating if cadmium was found.

Cadmium as a metal is on the priorities list and its use for plating food and beverage containers is not permitted. Evaporators, refrigerator shelves, and broiler grids for gas stoves are not regarded as food containers, but if these parts of equipment are cadmium plated, food poisoning may take place.

SUMMARY

Two outbreaks of acute cadmium

poisoning are described in which 7 persons became ill with acute gastritis within $\frac{1}{2}$ to 1 hour after partaking of drinks contaminated with cadmium. In contradistinction to cases reported in the past, the drinks were not in direct contact with cadmium plated utensils, but were contaminated by ice cubes exposed to drippings and scalings from cadmium plated evaporators of refrigerators. A survey of apartment houses with a newly developed field test, shows 25 per cent of the refrigerators of one manufacturer to be cadmium plated. The records of platers revealed refrigerator shelves and broiler grids had also been cadmium plated. Evidence obtained in this investigation points to the fact that this kind of plating is being done in other cities.

Biological Changes in Theiler's Virus of Spontaneous Mouse Encephalomyelitis*

CLAUS W. JUNGBLUT, M.D.

*Department of Bacteriology, College of Physicians and Surgeons,
Columbia University, New York, N. Y.*

IN 1934, Theiler¹ isolated and described the virus which causes so-called "spontaneous" encephalomyelitis in mice. Subsequent investigations led to the discovery of a number of significant facts all of which pointed to a striking similarity between this mouse disease and the symptomatology, pathology, and epidemiology of human poliomyelitis.² The fund of knowledge which has recently accumulated from the study of human strains of poliomyelitis virus in experimentally infected rodents serves to supplement these earlier findings in a number of ways which will be briefly reviewed.

To begin with, comparison of the physical constants of simian³ or of mouse-adapted⁴ poliomyelitis virus with those of the virus of natural mouse encephalomyelitis⁵ leaves an impression that all three viruses may be morphologically alike.

Second, it can be said that the pathological process which follows infection with the murine Lansing⁶ or the murine SK⁷ strains of human poliomyelitis virus is indistinguishable from that of Theiler's disease.⁸ What seems perhaps more significant is the fact that, while there are important differences between murine and human poliomyelitis with regard to the type and distribution of

nervous lesions, the classical picture observed in monkey and man is found again in guinea pigs which have been paralyzed by the cavian strain of SK poliomyelitis virus.⁷

Third, a number of facts may be related which suggest some antigenic relationship between Theiler's virus and mouse-adapted human poliomyelitis virus even though such a relationship cannot be demonstrated with simian poliomyelitis virus.⁹ For instance, Theiler,¹⁰ as well as Young and Cumberland,¹¹ reported that cotton rats or mice following survival from a paralyzing attack of mouse encephalomyelitis showed considerable protection against reinoculation with the murine Lansing strain. While the above authors failed to observe any corresponding cross-neutralization between the two viruses, serological analysis of the murine SK strain has revealed the existence of a broad, non-reciprocal immunological relationship which embraces all three viruses (RMV, SK, Theiler) that produce paralysis in man or mouse.¹²

The set of experimental results which has just been described finds further confirmation in certain epidemiological observations. Thus, recent investigation of a localized outbreak of poliomyelitis led to the isolation of two rodent-paralyzing agents, one from a child who had died of the disease, the other from a dead house mouse encoun-

*Aided by grants from the Philip Hanson Hiss, Jr., Memorial Fund, the Warner Institute for Therapeutic Research and anonymous donors

tered in the home of the same fatal case.¹³ The two viruses, except for their different virulence in mice, possessed similar fundamental characteristics; in addition, both were neutralized by convalescent sera from surviving patients as well as by antiserum against Theiler's virus.

That the above mentioned observations indicate some intimate connection between the etiological agents of poliomyelitis in man and of Theiler's disease in mice, is a matter which can scarcely be denied. Against the flat assumption, however, that both are identical stands the fact that the two viruses are narrowly restricted, in their natural as well as in their experimental host range, to man or mouse, respectively. Despite the failure of direct transmission of poliomyelitis virus from monkey to mouse—or of Theiler's virus from mouse to monkey—it is well known that certain strains of monkey or human virus may be transferred to albino mice by means of intermediary passage through cotton rats or hamsters.¹⁴ In view of the circumstances it has seemed of interest to explore the possibilities of adapting Theiler's virus, by serial cotton rat passage, from mice to other animal species, particularly monkeys and guinea pigs. The present communication sets forth in detail the results obtained in several such experiments.

EXPERIMENTAL WORK

The virus of spontaneous mouse encephalomyelitis used in this work was the so-called GDVII strain; it was received, in its 108th mouse passage, through the courtesy of Dr. Max Theiler from the Rockefeller Foundation. The virus was maintained in this laboratory in young Swiss albino mice by intracerebral transfer of 10 per cent brain suspensions obtained from paralyzed mice in serial passage.

Periodic titrations showed that this strain was highly virulent for young

mice upon intracerebral injection (10^{-6} to 10^{-8}); however when injected by the intraperitoneal route its titer was considerably lower (10^{-1}). While the high intracerebral infectivity of the virus was well maintained over a long series of mouse passages, the degree of its peripheral invasiveness showed marked fluctuations, particularly with the advent of the summer months. Thus, between June and September of two successive years, the percentage of paralysis in mice which had been infected by the intraperitoneal route, dropped to about 10 to 20 per cent as compared with a level of approximately 90 to 100 per cent paralysis during the remainder of the year. The nature of this seasonal fluctuation is unknown.

Repeated attempts to infect guinea pigs, albino rats, or rhesus monkeys by intracerebral injection with large doses of this virus failed to produce any recognizable signs of disease. Nor was it possible to recover any active virus by sacrificing some of these animals at short intervals after injection and transferring the brain substance to albino mice.

Of three Syrian hamsters injected with the 121st or 123rd mouse passages, one animal showed paralysis of the left front leg after an incubation period of 7 days, another animal developed prostrating paralysis of both front and hind legs on the 3rd day after injection, a third hamster remained free from any symptoms. Further transmission of the infection to new hamsters proved impossible even though the presence of active virus in the brain could be demonstrated by re-transfer to mice.

Numerous experiments confirmed Theiler and Gard's original observation¹⁵ that cotton rats are uniformly susceptible to the virus of mouse encephalomyelitis. All infected cotton rats, without exception, developed prostrating paralysis from 5 to 7 days after intracerebral injection, but no symptoms

Denominator = number of animals injected

were produced by intraperitoneal injection of large doses of mouse virus. The disease thus initiated could be maintained in successive cotton rat passages by intracerebral transfer of infected cotton rat brain and cord.

The pertinent data relating to these preliminary tests are given in Table 1.

I. TRANSMISSION OF THEILER'S VIRUS FROM ALBINO MICE TO COTTON RATS AND THE ESTABLISHMENT OF TWO FIXED STRAINS OF COTTON RAT VIRUS

Experiment I (October 31, 1941): Theiler's virus was transferred to cotton rats by using the brain of a freshly paralyzed mouse from the 109th mouse passage. The virus was carried in cotton rats through 21 serial intracerebral passages over a period of 13 months. In the first 3 cotton rat passages the incubation period varied between 5 and 4 days, in the next 3 passages between 4 and 3 days, thereafter, it became fixed at 2 days. Transfers from paralyzed

cotton rats to albino mice were carried out with the 1st, 2nd, 3rd, 6th, 9th, 15th, 17th, and 18th cotton rat passage; to guinea pigs with the 7th, 10th, 15th, 18th and 21st cotton rat passages; and to rhesus monkeys with the 3rd, 6th, 10th, and 15th cotton rat passages. Mice received the cotton rat virus by either intraperitoneal or intracerebral injection, monkeys and guinea pigs only by the intracerebral route. The results obtained with these transfers are brought together in Table 2.

It will be seen from Table 2 that the virus returned to mice from the first paralyzed cotton rat with titers of 10⁻³ intracerebrally, and 10⁻¹ intraperitoneally, but that with subsequent cotton rat passages (2nd, 3rd, 6th, 9th, 11th, 15th, 17th, and 18th) intraperitoneal titers between 10⁻⁴ and 10⁻⁶ were regularly observed; intracerebral titers continued to run at the usual level of about 10⁻⁶. Transfers to guinea pigs from earlier cotton rat passages (7th and 10th) produced no recognizable symp-

toms, but virus harvested from later cotton rat passages (15th, 18th, and 21st) proved capable of paralyzing all injected guinea pigs. Transfers from paralyzed cotton rats to rhesus monkeys induced fever or pareses of the extremities in practically all monkeys which had received virus from early as well as late cotton rat passages (3rd, 6th, 10th, and 15th). Intracerebral injection of normal cotton rat brain into monkeys produced neither fever nor any other signs of disease. Attempts to reproduce the above symptoms in continued monkey passages were unsuccessful but the virus returned readily to mice. All monkeys surviving without symptoms proved fully susceptible to intracerebral reinfection with monkey poliomyelitis virus (Aycok strain).

The results obtained in this experiment suggest that Theiler's virus, after passage through cotton rats, had undergone a profound biological change. In other words, Theiler's cotton rat virus displayed in peripherally infected mice marked invasive properties and proved pathogenic for guinea pigs and rhesus

monkeys upon intracerebral injection, characteristics which were not observed with Theiler's mouse virus. These new properties apparently were acquired as the result of a gradual adaptation in the cotton rat as the virus was passed serially in that animal. The adaptive nature of this process is also reflected by the progressive shortening of the incubation period in successive cotton rat passages, leading to eventual fixation of the virus.

Experiment II (March 30, 1942): The second experiment was carried out with the 116th mouse passage of Theiler's virus. The virus had been freshly prepared from an earlier glycerinated 115th mouse passage brain. The virus was carried in cotton rats through 11 serial intracerebral passages over a period of approximately 2 months. During this entire time the incubation period of the disease in cotton rats remained uniformly long, fluctuating within a range of from 4 to 7 days. Transfers from paralyzed cotton rats to mice (i.c. or i.p.), guinea pigs (i.c.) and rhesus monkeys (i.c.) were under-

taken with the 1st, 3rd, and 5th cotton rat passages. The results obtained with these transfers are shown in Table 3.

It appears from Table 3 that the virus returned to mice from all three cotton rat passages tested with titers of 10⁻⁵ intracerebrally and 10⁻¹ intraperitoneally; also, that virus from the same cotton rat passages produced no symptoms in guinea pigs or rhesus monkeys.

The results of this experiment were therefore at variance with those obtained in the first experiment in that Theiler's virus, after several cotton rat passages, failed to show any increased invasiveness for albino mice and proved to be wholly non-pathogenic for rhesus monkeys. In the absence of any good reasons which might explain the discrepancy it was decided to repeat the experiment with a mouse brain passage as close as possible to the one used in the first successful experiment.

Experiment III (May 29, 1942): The 110th mouse passage of Theiler's virus was used for the third experiment. The sample employed had been freshly prepared from the 109th glycerinated mouse passage. The virus was carried in cotton rats through 12 serial intracerebral passages over a period of about 7 months. The incubation period of the disease in cotton rats changed very abruptly from 4 days in the first pas-

sage to 2 days in the second passage and thereafter was maintained at the 2-3 day level throughout all subsequent transfers. Transfers from paralyzed cotton rats to albino mice (i.c. or i.p.) were carried out with the 1st, 2nd, 3rd, 5th, 6th, 7th, and 9th cotton rat passages; to guinea pigs (i.c.) with the 2nd, 3rd, 5th, and 9th cotton rat passages; and to rhesus monkeys (i.c. or i.v.) with the 2nd, 3rd, 5th, and 10th cotton rat passages. The results of these transfers are listed in Table 4.

It may be seen from Table 4 that the virus returned to mice from all cotton rat passages tested with marked intraperitoneal potency (10⁻⁸ to 10⁻⁴), intracerebral titers being slightly above normal limits (10⁻⁹ to 10⁻⁶). Injection of guinea pigs with early cotton rat virus produced paralysis irregularly but transfer from the 9th cotton rat passage proved capable of paralyzing all injected guinea pigs. Transfers to rhesus monkeys from either early or late cotton rat passages were followed by no symptoms in four monkeys, but caused an encephalitic syndrome in two monkeys and bulbar paralysis in one monkey; the latter animal had received a large dose of cotton rat virus by the intravenous route, whereas all other monkeys had been injected intracerebrally with small doses of virus. The disease could not

be further transmitted from monkey to monkey, but the virus returned readily to mice.

The results obtained in this experiment are in agreement with the observations made in the first experiment in that cotton rat passage had evidently brought about some change in Theiler's virus which served to enhance its peripheral infectivity for mice and enabled it to induce paralysis in guinea pigs as well as encephalitis or bulbar paralysis in rhesus monkeys. As compared with the first successful experiment, the adaptation in this experiment was of an explosive character, leading to a more rapid fixation of the virus in cotton rats and to an earlier development of pathogenicity for guinea pigs and rhesus monkeys.

In view of the diverging results obtained in three different experiments it seemed advisable to repeat the transmission of Theiler's virus from mice to cotton rats once more with another mouse brain passage.

Experiment IV (July 9, 1942): The passage closest to the 109th and 110th which was available was the 113th serial mouse transfer. A fresh 114th passage

was prepared from the glycerinated brain and used for the fourth experiment. The virus was carried in cotton rats through 6 serial intracerebral passages over a period of about 5 months. The incubation period of the disease in cotton rats was uniformly long throughout the entire period, fluctuating between 8 and 5 days. Transfers from paralyzed cotton rats to albino mice were carried out with the 1st, 2nd, and 5th cotton rat passages. The results obtained with these transfers are given in Table 5.

It will be noted from Table 5 that the virus returned to mice from all cotton rat passages tested with exceptionally low potency, i.e., intracerebral titers reached only 10⁻³ and the virus failed to infect mice intraperitoneally with doses as large as 10⁻¹. The negative results of this experiment compare with those obtained in the second experiment in that Theiler's mouse virus, after passage through cotton rats, gave no evidence whatsoever of having acquired any enhanced infectivity for albino mice.

In summarizing the data available from four different experiments in which

TABLE 5

VI	11-12-42	6 days		

various mouse passages of the GDVII strain of Theiler's virus were transmitted from mice to cotton rats, with subsequent serial sub-passage through cotton rats, it appears that on two occasions (109, 110 lines) the virus became fixed in the new host and, coincidental with such fixation, had acquired new biological properties. These were reflected (a) by an enhanced peripheral infectivity for albino mice, and (b) by the ability to induce various types and degrees of central nervous system infection in guinea pigs and in rhesus monkeys. A detailed description of the clinical symptoms and pathological findings in these monkeys will be found at the end of this paper. Whatever viral changes had occurred were evidently of a permanent nature since continued sub-passage of these cotton rat viruses in albino mice (10 serial mouse passages for the 109 line and 4 serial mouse passages for the 110 line of cotton rat virus) did not depress their enhanced intraperitoneal titer for albino mice. It is equally clear, however, that on two other occasions (116, 114 lines) the virus was not appreciably affected in its biological properties after having been subjected to a series of cotton rat passages.

The reasons for this discrepancy are unknown. It is conceivable that factors connected with the nature of the seed, or the receptivity of the cotton rat, or the cycle of the season spell the difference between success and failure, but

our observations offer no tangible information on any of these points. The possibility must finally be considered that the virus recovered from paralyzed cotton rats may have been a contaminating virus, derived either from a latent virus carried by the cotton rats themselves, or introduced through inadvertent infection of cotton rats with a similar virus propagated in this laboratory. The first of these two alternatives seems hardly plausible. To begin with, Theiler's cotton rat virus (110 line) was highly infectious for cotton rats not only by the intracerebral route but paralyzed these animals also by intraperitoneal injection in dilutions up to 10⁻⁷ after an incubation period of 3 days. Moreover, a series of 9 successive cotton rat passages, initiated by the intracerebral injection of heat-inactivated Theiler mouse virus and propagated serially with the brains of symptomless cotton rats, sacrificed at 5 day intervals, failed to reveal the presence of any paralyzing agent through the entire period. The second alternative cannot be lightly dismissed inasmuch as Theiler's cotton rat virus possesses certain properties in common with the murine SK strain of poliomyelitis virus previously described from this laboratory. It therefore seemed of interest to transmit SK murine virus from mice to cotton rats and maintain serial cotton rat passages for several generations, with the object of comparing the course of the infection and the nature of SK cotton rat virus with similar data

pertaining to Theiler's cotton rat virus.

Experiment V (April 23, 1942): The 273rd serial mouse passage of SK murine virus was used for this experiment. The virus was carried in cotton rats through 8 serial intracerebral passages over a period of about 8 months. The incubation period of the disease in cotton rats, beginning with the first passage, was uniformly short (2 days) and remained pegged at this level throughout the entire experiment. In spite of high intracerebral potency, SK cotton rat passage virus displayed only moderate peripheral invasiveness for cotton rats, as indicated by an intraperitoneal titer of 10^{-3} . Transfers from paralyzed cotton rats to mice were carried out with the 1st, 2nd, 3rd, and 6th cotton rat passages; to rhesus monkeys with the 1st cotton rat passage. The results of this experiment are brought together in Table 6.

As may be seen from Table 6, the

similarities between the two disease agents. Both viruses were indistinguishable with reference to their high intracerebral and intraperitoneal potency for albino mice and both were pathogenic for rhesus monkeys to various extent. They differed, however, in at least two significant respects. Thus, the transfer of Theiler's virus from mice to cotton rats assumed the pattern of an adaptive process which led to a gradual shortening of the incubation period in successive cotton rat passages, with eventual fixation of the virus; on the other hand, the transfer of SK virus from mice to cotton rats proceeded with a minimum incubation period from the first to the last passage, giving no evidence that the virus had undergone any form of adaptation. Moreover, fixed cotton rat Theiler virus was considerably more invasive for cotton rats peripherally (i.p. titer 10^{-7}) than was fixed cotton rat SK virus (i.p. titer 10^{-3}).

VIII	12-14-42	2 days			

virus returned to mice from all cotton rat passages tested with uniformly high intracerebral (10^{-7}) and intraperitoneal (10^{-6}) titers and caused transient fever, but no other symptoms, in the two monkeys injected with virus from the first passage.

A comparison of the results obtained with Theiler's cotton rat virus (lines 109 and 110) and with SK cotton rat virus brings out certain similarities and dis-

The above data, while demonstrating some fundamental differences between Theiler cotton rat virus and SK cotton rat virus, are admittedly insufficient to permit of clear distinction between the two disease agents. It therefore became necessary to resort to cross-protection and cross-serological tests in order to provide the basis for a sharper differentiation of the two viruses on immunological grounds.

II. CROSS-PROTECTION TESTS BETWEEN THEILER'S MOUSE VIRUS, THEILER'S COTTON RAT VIRUS, AND SK COTTON RAT VIRUS

It is well known that mice which have passed through previous infection with

10^{-2} and 10^{-6} . At the same time an adequate number of normal control mice, of similar age as the immunized mice, were infected with the three viruses in the same dosage. The results are shown in Table 7.

TABLE 7

Reinfection of Mice Immune to Theiler's Mouse Virus with Theiler's Cotton Rat Virus or SK Cotton Rat Virus

Immunized Mice	Reinfection				Controls			
	Virus	Dose i.p.	Paralysis	Per cent	Virus	Dose i.p.	Paralysis	Per cent
Immunized with Theiler's mouse virus	Theiler's cotton rat virus (109th line)	10^{-2} — 10^{-6}	35/39	90	Theiler's cotton rat virus (109th line)	10^{-2} — 10^{-6}	35/39	90
	Theiler's cotton rat virus (110th line)	10^{-2} — 10^{-6}	16/29	55	Theiler's cotton rat virus (110th line)	10^{-2} — 10^{-6}	31/31	100
	SK cotton rat virus	10^{-2} — 10^{-6}	26/27	96	SK cotton rat virus	10^{-2} — 10^{-6}	40/40	100

Numerator = number of mice paralyzed
Denominator = number of mice used

Theiler's mouse virus, even though developing no symptoms, nevertheless acquire a relatively high degree of resistance against subsequent reinfection with the same virus. It was therefore thought that this fact might form a convenient basis for a screening test useful in separating individual virus entities belonging to a group of generally related viruses. Accordingly, an experiment was planned in which mice were actively immunized against Theiler's mouse virus and then reinfected with the three apparently similar viruses on hand, i.e., SK cotton rat virus and the two highly pathogenic strains of Theiler cotton rat virus (109 and 110 lines).

A group of 150 young mice, over a period of 2 weeks, received three doses of 0.1 ml. each of 10 per cent Theiler mouse virus by the intraperitoneal route. After an interval of 1 week, dating from the last injection, there were available for further tests a total of 95 mice (55 mice having died with paralysis during the course of immunization). The surviving mice were subdivided into three groups and reinfected intraperitoneally with either SK cotton rat virus or with Theiler cotton rat virus (109 or 110 lines), doses ranging between 0.1 ml.

As will be seen from Table 7, mice immune to Theiler mouse virus had remained fully susceptible to subsequent inoculation with either SK cotton rat virus or one strain of Theiler cotton rat virus (109 line); on the other hand, the incidence of paralysis following reinfection with the other strain of Theiler cotton rat virus (110 line) was approximately half of that occurring in corresponding normal control mice. The foregoing experiment therefore offers suggestive evidence that at least one of the two highly pathogenic strains of Theiler cotton rat virus was antigenically more closely related to Theiler's mouse virus than was SK cotton rat virus. But since the data fell short of providing a decisive answer to the problem under discussion it became imperative to carry out detailed cross-neutralization tests with the various viruses and their corresponding antisera.

III. CROSS-NEUTRALIZATION TESTS BETWEEN THEILER'S MOUSE AND COTTON RAT VIRUSES AND SK MOUSE AND COTTON RAT VIRUSES BY THEIR CORRESPONDING ANTISERA

The principle of cross-neutralization was employed in these tests in an effort

to utilize the serological reactivity of certain critical virus-antiserum combinations as a method for determining the nature of the highly pathogenic strains of Theiler's virus obtained by passage through cotton rats. It seemed reasonable to assume that such cotton rat virus should be neutralized by antiserum against Theiler's mouse virus and that some neutralization would likewise be demonstrable between Theiler's mouse virus and an antiserum against Theiler's cotton rat virus. Conversely, it might be taken for granted that SK cotton rat virus would show neutralization with an antiserum against SK mouse virus and that SK mouse virus, in turn, would be neutralized by antiserum against SK cotton rat virus. It is also clear, on the other hand, that marked cross-reactions

were not expected to occur between the two Theiler viruses and antisera prepared against the two SK viruses, or vice versa, provided the highly pathogenic strains of Theiler's cotton rat virus had been derived from Theiler's mouse virus and not from accidental contamination with SK virus.

All neutralization tests were carried out in young albino mice. The viruses were obtained from freshly harvested infected mouse brains. Antisera against the four viruses on hand (Theiler mouse virus, Theiler 110 cotton rat virus, SK mouse virus, SK 273 cotton rat virus) were produced by immunizing rabbits with slowly increasing doses of 5 to 10 per cent virus mouse brain emulsions, administered by both intravenous and intraperitoneal injection over a period

Technic: Antiserum and virus (SK mouse, SK cotton rat, Theiler cotton rat) were combined in amounts of 0.1 ml. each and the mixture, after incubation for 1 hour at 37° C. was injected intraperitoneally in a volume of 0.2 ml. In case of Theiler's mouse virus, 0.2 ml. of virus and 0.2 ml. of antiserum were used and the mixture was injected in a volume of 0.4 ml.

Numerator = number of mice paralyzed

Denominator = number of mice injected

of 1 month. Final bleedings were collected after a rest period of 1 week. Antisera, in various dilutions, were combined with a constant amount of virus; the mixtures were incubated for 1 hour at 37° C. and then injected intraperitoneally, in a volume of 0.2 ml. or 0.4 ml. each, into several mice. This method was chosen since preliminary tests had demonstrated that little or no neutralization was obtainable with any of these viruses and their corresponding antisera upon intracerebral injection. Normal rabbit serum was used for control purposes. The results are shown in Table 8.

The data presented in Table 8, barring some minor irregularities, are sufficiently clear and comprehensive to permit of unequivocal interpretation. It will be observed that each monovalent antiserum, in high dilutions, neutralized not only its specific virus but was also capable of inactivating its correspondingly related virus at similar levels of dilution. On the other hand, little or no cross-reactions occurred between these antisera and unrelated viruses, except with low dilutions of serum when overlapping was almost universal. For example, SK mouse virus antiserum neutralized SK mouse virus or SK cotton rat virus at titers of 1:500 or 1:100, respectively, whereas the same serum showed no neutralization or a neutralizing titer of only 1:1 with Theiler's mouse virus or with Theiler's cotton rat virus. Again, Theiler mouse virus antiserum neutralized Theiler's mouse virus or Theiler's cotton rat virus at titers of 1:500 or 1:100, respectively, while the same serum brought about neutralization of SK mouse virus or SK cotton rat virus at titers of only 1:1 or 1:10. Another approach is possible by examining the extent to which a given virus was neutralized by the various monovalent antisera. For example, SK mouse virus was neutralized by both, SK mouse virus antiserum or SK cotton rat virus antiserum, at a titer of 1:500 whereas

Theiler mouse virus antiserum or Theiler cotton rat virus antiserum inactivated the same virus at a titer of only 1:1. Conversely, Theiler mouse virus was neutralized by both, Theiler mouse virus antiserum and Theiler cotton rat virus antiserum, at a titer of 1:500 while SK mouse virus antiserum or SK cotton rat virus antiserum showed no neutralization or a neutralizing titer of only 1:1 against the same virus.* Essentially similar results were obtained with an antiserum prepared by immunization with Theiler 109 cotton rat virus.

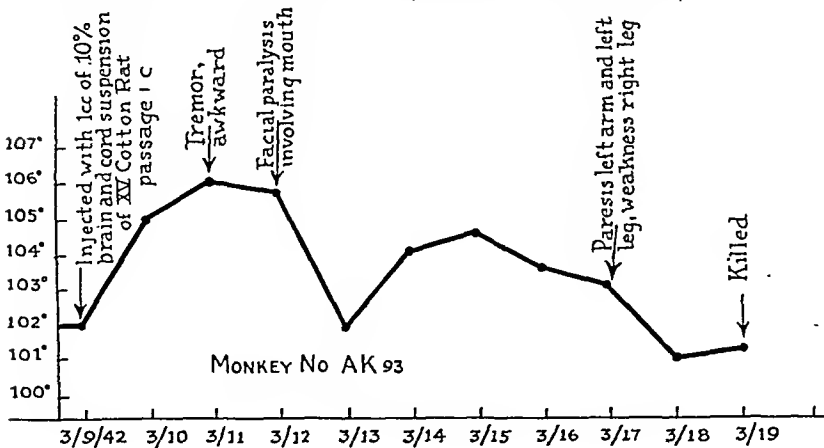

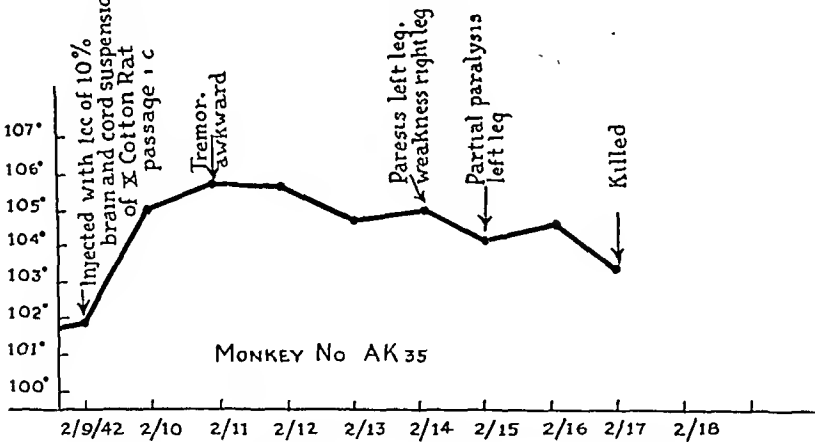

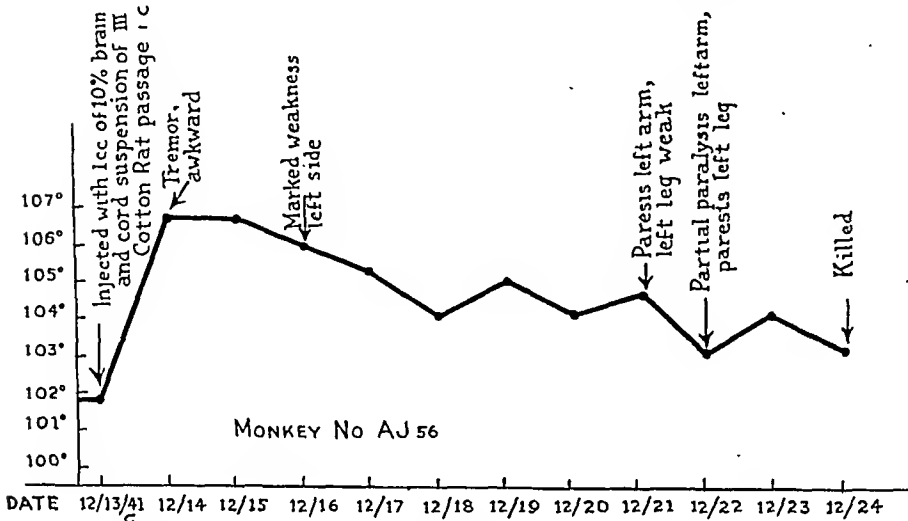

The above facts indicate clearly that Theiler's cotton rat virus is serologically identical with Theiler's mouse virus but differs markedly from SK mouse virus. It is therefore obvious that the cotton rat variant could not have been derived from accidental infection with SK virus. While differentiation is thus possible by the use of quantitative methods, the data also reveal the basic immunological relationship which exists between the various rodent viruses.

DISCUSSION

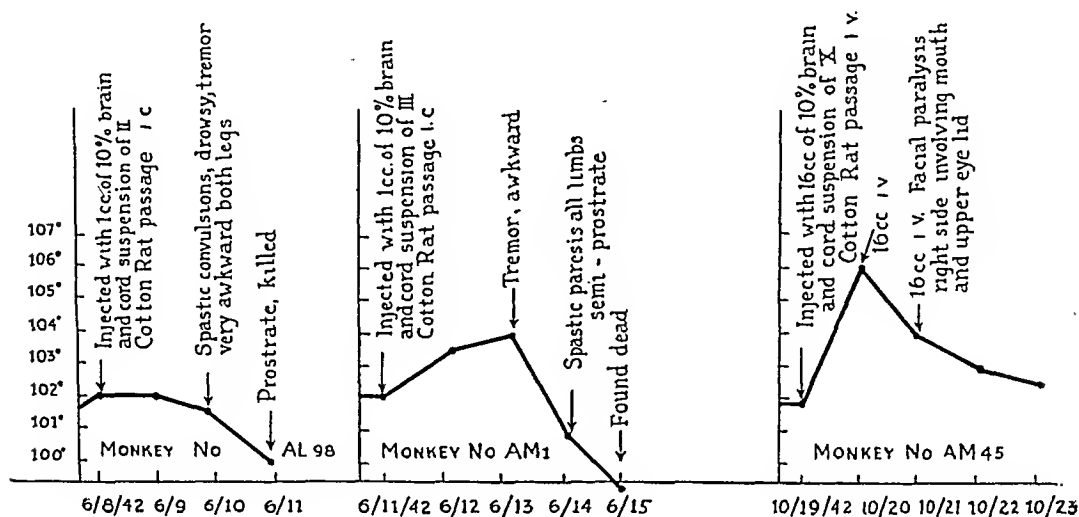

The virus of mouse encephalomyelitis—whether isolated from the central nervous system of spontaneously paralyzed mice or derived from the intestinal tract of healthy carrier mice—possesses certain basic properties which distinguish it from most other neurotropic viruses. These properties may briefly be summarized as follows: (1) limitation of natural host range to albino mice, (2) marked disproportion between high intracerebral potency and low peripheral infectivity for albino mice, and (3) specific neutralization by immune principles developed in adult mouse serum as the result of latent in-

* The total absence of neutralization between SK mouse virus antiserum and Theiler's mouse virus reported here differs from earlier observations in which some cross-neutralization had been described.¹² The fact that in this study a rabbit antiserum was used and in the earlier work a horse antiserum might conceivably account for this difference.

CLINICAL RECORD OF RHESUS MONKEYS WHICH DEVELOPED NERVOUS SYMPTOMS FOLLOWING INJECTIONS WITH THEILER'S COTTON RAT VIRUS (109th LINE)

CLINICAL RECORD OF RHESUS MONKEYS WHICH DEVELOPED NERVOUS SYMPTOMS FOLLOWING INJECTION WITH THEILER'S COTTON RAT VIRUS (110th LINE)

fection. Taken together, these characteristics attest to the nearly perfect state of symbiosis which this virus has been able to achieve with its host in the course of time.

When mouse passage strains of Theiler's virus are tested in rodents free from this virus, they also fail to exhibit any *invasive* properties despite their high intracerebral potency. Thus, intraperitoneal injection of massive doses of the GDVII strain causes no paralysis in wild-caught cotton rats even though the same animals discharged no virus with their feces and harbored no neutralizing antibodies in their serum. Interestingly enough, however, cotton rats like albino mice are also susceptible to symptomless infection with Theiler's virus by natural routes; for after prolonged laboratory contact with albino mice, Theiler's virus could readily be demonstrated in cotton rat feces. It would seem, therefore, that the low grade character of the infection, which is pathognomonic of Theiler's disease in mice, is essentially due to the action of a degraded virus rather than

to any restraining effect of herd immunity.

If it were feasible to propagate Theiler's virus systematically on virgin susceptible soil, an increase in virulence and invasiveness of the infectious agent might well be expected to occur. In other words, after serial passage through a proper intermediary host, Theiler's virus should show signs of an enhanced capacity to infect mice by peripheral routes; the gain in virulence might conceivably be sufficiently marked to permit the production of paralysis in other animal species normally refractory to the virus. It goes without saying that such newly acquired qualities could distort the familiar picture of the original virus almost beyond recognition. However, satisfactory evidence of the identity of the parent virus and its variant would be on hand provided the antigenic properties had been preserved during this process.

The data reported in this paper may be regarded as substantiating the hypothetical case outlined above. Thus, in

two of four different experiments in which Theiler's virus was transmitted from mice to cotton rats, with subsequent serial subpassage in the latter animals, the virus became fixed in the new host and acquired new and enduring biological properties. To wit, the cotton rat strains showed greatly enhanced peripheral infectivity for albino mice and were

capable of inducing various types and degrees of central nervous system involvement in guinea pigs and in rhesus monkeys. The lesions thus produced in monkeys are interesting for more than one reason. Their selective localization in either brain or cord illustrates the wide range of neurotropic affinity while their marked tendency for unilateral distribution reveals the limited invasive

power of the virus in this host. Serological analysis in which Theiler's mouse virus and its cotton rat variant were subjected to cross-neutralization tests demonstrated clearly that the two strains were essentially identical in antigenic behavior. These tests also left no question that Theiler's cotton rat virus differed from SK cotton rat virus to the same extent as did Theiler's mouse virus

from SK mouse virus. It may therefore safely be concluded that the observed transformation of Theiler's mouse virus was authentic, even if the key which controls this phenomenon is not yet at our disposal. A similar lack of regularity in results has been characteristic of all attempts to adapt human virus from monkeys to cotton rats and mice.

The process which led to these re-

markable changes of Theiler's virus had the earmarks of an induced variation. However, while the increase in virulence was permanent for rodents, it was only transient for monkeys, thus demonstrating the intrinsic incompleteness of viral adaptation. In its fundamental aspects, this variation is not unlike the R-S variation so well known from the study of dissociation phenomena among patho-

genic bacteria. While the analogy can only be a superficial one, it is an attractive speculation to imagine that loss and gain of invasiveness in a virus may follow a relatively simple pattern, similar to what applies to the higher forms of microörganismal life.

The above mentioned facts form the nucleus of a broader biological concept which would rate the virus of human

poliomyelitis and the virus of mouse encephalomyelitis as descendants from a common primitive viral root. Because of extreme adaptation to man or mouse, both viruses have evidently emerged as essentially monopathogenic agents, incapable of producing disease in the natural host of the other. An exchange of pathogenicity, however, seems to be possible by passing these variants through a mutually susceptible environment. The term "poliomyelitis group" is therefore proposed as an appropriate designation for both the human and rodent strains. Placing these viruses together into such a system of natural classification not only does justice to their many striking similarities but opens the way for a better appreciation of the epidemiology of the human disease.

CONCLUSIONS

1. In two of four experiments, in which Theiler's virus of mouse encephalomyelitis was transmitted to cotton rats—with subsequent serial subpassage in the latter animals—the virus became fixed in the new host and acquired new biological properties.

2. These properties were reflected (a) by a marked increase in peripheral invasiveness for albino mice and cotton rats, and (b) by the ability to induce various types of central

nervous system involvement in guinea pigs and in rhesus monkeys.

3. Evidence is adduced to show that the cotton rat variant was serologically identical with the parent virus.

The Etiology of Malignant Diphtheria

MARTIN FROBISHER, JR., Sc.D., F.A.P.H.A.

Department of Bacteriology, The Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

THE clinical syndrome variously known as malignant diphtheria, hypertoxic diphtheria, and diphtheria gravis or grave diphtheria, may have been known, although under other names, for centuries. Descriptions are found in the writing of Hippocrates and in medical works of the 2nd century A.D., and elsewhere, which depict conditions agreeing more or less exactly with the modern definition of the disease. As distinguished today, malignant diphtheria is characterized usually by sudden and severe onset, with vomiting, high fever, and cardiac failure. Cervical adenopathy is marked, giving the "bull neck" commonly associated with the disease. Oral fetor and sanguinous nasal discharge are frequent, as is also albuminuria. The tonsils are usually excessively swollen, but pseudomembrane formation may be slight. *Corynebacterium diphtheriae* can regularly be obtained from the pharynx or tonsils. Drowsiness and cyanosis develop rapidly, and in spite of early, frequent, and large doses of antitoxin, death often supervenes in from 24 to 72 hours after onset. Adults and older children are frequently attacked.

The prevalence of very severe or malignant diphtheria has apparently fluctuated greatly from time to time. We may infer from writings of the early 18th century that it was a common scourge, sometimes referred to as "morbus suffocans" or "angina maligna," widespread in Europe and America. In succeeding years, the dis-

ease became less of a plague and, in the United States today, the severity of diphtheria, as well as its morbidity and mortality, is much less than formerly. In modern times, outbreaks of the malignant disease have been of a localized nature and have not spread widely, although during the period 1925 to 1935 there was a widespread increase in malignant diphtheria in Germany and other European countries. The case fatality rate in Berlin rose from about 5 per cent to around 27 per cent between 1924 and 1927.^{1, 2} A large outbreak was studied in Leeds, England, in 1929-1930 by Anderson, *et al.*³ In this hemisphere a smaller epidemic of the same nature was observed in 1936 in Belair, Md., by the writer, in cooperation with physicians of the Maryland State Health Department. In 1941 a severe outbreak occurred in Halifax, N. S., and has been described by Morton,⁴ Campbell,⁵ and Wheeler and Morton.⁶ Numerous similar occurrences have been described in various parts of the globe.

The striking clinical features of malignant diphtheria as contrasted with those of the so-called "ordinary," or relatively mild diphtheria, have stimulated many workers to investigate the types of diphtheria bacilli involved in the former, with the hope of finding cultural or other properties which would explain the severity of the malignant disease, and furnish some clue as to why antitoxin is so often ineffective in such cases. Other workers have made studies on the prevalence of malignant

diphtheria and the relation of certain specific types of bacilli to it. Due to variations in epidemiological and bacteriological technics in these studies, and because of failure to define terms clearly, an unfortunate confusion has arisen between clinical and bacteriological terminology. It is one of the purposes of this paper to attempt some clarification of this situation.

Other aims of this discussion are to make additional suggestions concerning the etiology of malignant diphtheria and to present a summary of our present knowledge of the prevalence of the disease, and of *C. diphtheriae* of the so-called gravis type, in the United States.

I. CONFUSION BETWEEN CLINICAL AND BACTERIOLOGICAL TERMINOLOGY

Hammerschmidt,⁷ in 1924, differentiated 3 main cultural types of *C. diphtheriae* in Germany, but his work has remained relatively obscure, possibly because he attached no clinical importance or names to the types of diphtheria bacilli described by him. In 1931, Anderson, *et al.*, at Leeds, England³ described their now well known gravis and mitis types of diphtheria bacilli (the clinical implications inherent in these names being obvious), and indicated a causal relationship of *C. diphtheriae* gravis to malignant diphtheria.*

Confusion in terminology arose when attempts were made in various parts of the world to confirm the results of the Leeds workers. It appeared that, for

the time and place of the studies, their clinical observations and laboratory observations, regarded as separate groups of data, were correct, i.e., the severe cases were characteristic of malignant diphtheria, and bacteriological descriptions were accurate. However, while the conclusions of the Leeds workers as to the causal relationship between malignant diphtheria and *C. diphtheriae* gravis received some confirmation,⁸⁻¹⁴ many observers indicated that these conclusions were overgeneralized. For example, in other areas numerous strains *culturally* typical of the gravis type, were shown to be wholly avirulent as determined by the ordinary laboratory tests.¹⁵ Outbreaks of diphtheria were seen in which the majority of severe and fatal cases, or many of them, were said not to be due to the gravis type of bacilli, but to strains having the cultural characters of the mitis or indeterminate types.¹⁶⁻¹⁹ Patients with mild diphtheria, as well as healthy carriers, were found to harbor organisms indistinguishable from the gravis type of organism¹⁵ and several workers found little, if any, significant relationship between cultural type of organism and clinical picture.^{9, 20-25, 28-32} In addition, several workers had trouble in differentiating the cultural types of bacilli, or found them quite unstable and even interchangeable at will.^{16, 26-29}

It is difficult to evaluate most of this work because only two or three writers described their types of *C. diphtheriae*

* A rather close similarity may be noted between Hammerschmidt's group A and the mitis type of Anderson, *et al.*, and between the group C of the former and the gravis type of the latter. The differential characters used by each for distinguishing their principal groups or types were as follows:

Author	Type or Group	Colony on	Hemolysis	Growth in Broth	Final Reaction in Broth †	Fermentation of		Pellicle formation
		Tellurite Agar	in Test Tube			Starch	Glycogen	
Hammerschmidt	Group A	smooth	+	even turbidity	alkali			
Anderson, <i>et al.</i>	Mitis type	smooth	+	even turbidity	acid	—	—	—
Hammerschmidt	Group C	rough	—	granular	acid			
Anderson, <i>et al.</i>	Gravis type	rough	—	granular	alkali	+	+	+

† Most of Hammerschmidt's findings regarding types have been confirmed, but his results with regard to reaction in broth have not.

TABLE 1

<i>Authors</i>	<i>Criteria Used to Determine Gravis Types by Authors Cited</i>	<i>No. of Gravis Strains, According to Varied Criteria among 237 Cultures of All Types</i>
Parish, Whatley, and O'Brien ²²	Starch fermentation, pellicle formation	19
Christison, Wright, and Shearer ⁶⁸	Starch fermentation, colony form	9
Dockeray ²⁰	Starch fermentation	43
Tannhil ¹⁷	Starch, colony, pellicle	6 *
Mair ²⁷	Same as above	6 *
Schiff and Werber ¹²	Starch, colony, pellicle, hemolysis	6 *
Carter ¹⁵	Glycogen, starch, colony	6 †
Wright and Rankin ²³	Glycogen, starch, colony, morphology, hemolysis	6 †
Gregory ⁶⁹	Starch, colony	9
Anderson, <i>et al.</i> ³ (original Leeds workers)	Glycogen, starch, colony, morphology, pellicle, hemolysis, reversion of pH	4

* † The 6 strains in each group marked with an asterisk were the same, but were entirely different cultures from the 6 strains in the 2 groups marked with a dagger. Which are the true gravis strains?

in exactly the same terms. Many give no cultural details at all, and others are widely divergent in this respect, not only from each other but from the original, 1931, description as well. The difficulty is partly illustrated in Table 1. This table was prepared by applying the varied criteria used by several different writers for identifying gravis strains of diphtheria bacilli, to a group of 237 cultures studied by the author and his coworkers in Baltimore. All the significant characters of the latter cultures conformed to the original Leeds description and all had been determined in one laboratory. Obviously, the interpretations of many authors are open to question. In 1939, diphtheria in Leeds was restudied.³³ In the new study, however, a modified method of type determination was used, which is unfortunate in view of the confusion which had already arisen. The situation is not clarified by the recent review by one of the Leeds workers.³⁵

The importance of uniform technic has previously been pointed out: "If reports upon the occurrence of gravis

and mitis and intermediate types of *C. diphtheriae* in different parts of the world are to be comparable, the criteria of identification must be equivalent. The designations are not valid unless the strains under consideration have been shown to conform fairly closely to the criteria originally set up by Anderson, *et al.*, as characteristic . . . Failure of many investigators to describe in detail the full complement of the biochemical characters of their 'gravis,' 'mitis,' and intermediate types, or the methods by which they were determined, or both, renders almost fruitless much of the work in the field."³⁴

Because there has been such diversity of opinion as to the exact meaning of the terms *C. diphtheriae* gravis and *C. diphtheriae* mitis, it has been thought desirable to state clearly what is implied in our own use of these terms. In the present report, as in previous studies by the same author and his coworkers, strains of *C. diphtheriae* have been classed as mitis or gravis if, in addition to possessing the usual morphological and fermentative properties of *all* cul-

tures of *C. diphtheriae*, they have reacted as follows when tested by methods previously described.³⁴

	<i>Gravis</i>	<i>Mitis</i>
Fermentation of starch	+	—
Fermentation of glycogen	+	—
Colony	rough	smooth
Hemolysis (broth)	—	+
Final pH in broth	7.5 or above	7.4 or below
Growth in broth	granular	even turbidity
Pellicle	+	—

These are the characters (except morphological details generally found to be of little differential value) originally described by the Leeds workers. In our usage, individual strains of either the mitis or gravis type *may or may not be virulent*, and they may come from any source. Cultures classed as gravis-like or mitis-like may be lacking in one or two of the more variable characters such as final pH, hemolysin production, or pellicle formation. Indeterminate strains are those which are not predominantly mitis-like or gravis-like in character. The so-called intermediate type is included by us with indeterminate strains. It might be stated also that, although some strains retain their gravis or mitis characters with some tenacity, in our hands many have changed greatly and are quite variable.

The definition given above, while in disagreement with some other writers, has the virtues of clarity and of agreement with the *original* description in point of cultural characters, if not in regard to virulence and source. *C. diphtheriae* gravis, as the term has been used by us, is thus clearly defined as a cultural variety without regard to any clinical or epidemiological significance. Additional reasons for thus divorcing biological properties from all clinical or epidemiological implications will be given farther on in this paper.

In addition to misunderstandings arising from misuse of bacteriological terms as just described, clinical ambiguity has arisen from use of the term "gravis diphtheria" or "diphtheria

gravis" with inadequately defined meaning. One should state clearly whether, by gravis diphtheria, he means a case of diphtheria characterized by all (or only some) of the clinical features of the malignant disease, as set forth in a foregoing paragraph, without regard to the cultural type of diphtheria bacilli present, or whether, regardless of clinical features, he means a case from which a strain of *C. diphtheriae* culturally of the gravis type was isolated, or whether, on the other hand, a malignant case associated with bacilli having the cultural properties of *C. diphtheriae* gravis is meant. The question has also been raised whether the terms "gravis diphtheria" and *C. diphtheriae* gravis should not be restricted to cases and cultures occurring during *epidemics* of the malignant disease. This uncertainty further complicates both clinical and epidemiological discussion, to say nothing of perplexities arising from serious doubts, to be discussed presently, as to the ability of *C. diphtheriae* gravis, per se, to cause malignant diphtheria at all. These difficulties have not been very fully discussed by McLéod in his review of the present status of the gravis and other types of *C. diphtheriae*,³⁵ and seem to have been almost wholly unknown to the writer of a recent rather naïve editorial on the subject.³⁶

II. THE ETIOLOGY OF MALIGNANT DIPHTHERIA

1. *Relationship of C. diphtheriae gravis to the disease*—As noted above, serious objections have been raised against accepting *C. diphtheriae* gravis as the *sine qua non* of malignant diphtheria. Several experimental and other details are of special interest in this connection. For example, one of the salient features of malignant diphtheria is refractoriness to diphtheria antitoxin. This has been ascribed by some to a peculiarity of the exotoxin of *C.*

diphtheriae gravis. However, experimental investigations^{14, 22, 25, 37} of this matter have shown conclusively that the exotoxins of all known types of *C. diphtheriae* are qualitatively identical. Zinnemann and Zinnemann,¹⁴ reporting a series of investigations on the use of commercial toxoid and antitoxin in the control of hypertoxic diphtheria stated that ". . . in work on guinea pigs the preparations in common use today are of value in controlling both infections with gravis strains, and gravis intoxications." This is in agreement with earlier findings of Parish, Whatley, and O'Brien.²²

Curiously enough, experimental evidence also indicates that gravis strains of *C. diphtheriae* are often inefficient toxin producers in laboratory media.^{38, 39, 40} Not only are they poor toxin producers under such circumstances but, as shown by studies conducted in this laboratory, many strains are completely atoxigenic as ordinarily tested. This was the case, for example, in 1938-1939 in Virginia, where 7 of 11 carrier cultures of the gravis or gravis-like types were avirulent, while in Alabama, 28 of 40 carrier cultures of the same variety were avirulent.⁴¹ Although virulent gravis strains were common in the populations investigated, diphtheria morbidity was very low indeed and malignant diphtheria entirely absent so far as can be determined. Later studies showed that the presence of virulent gravis strains was not significantly associated with malignant diphtheria elsewhere in the United States at the time the studies were made.

Obviously, the mere presence alone of diphtheria bacilli which are culturally of the gravis type, at least in the form in which they appear in laboratory cultures as at present prepared, is not in itself sufficient to cause malignant or hypertoxic diphtheria, although the organisms appear to be associated with the disease in certain outbreaks. We

are therefore led to the conclusion that malignant diphtheria is due to (a) some property of *C. diphtheriae* other than any of these demonstrated in the laboratory by methods currently in use, or (b) some wholly extrinsic agent or agents acting in combination with *C. diphtheriae*, or (c) variations in host resistance.

2. *Factors possibly responsible for the malignancy of diphtheria*—If we arrange the factors involved in the development of malignant diphtheria in their natural relationship to each other, we might formulate an equation somewhat as follows:

$$\frac{\text{Toxigenicity of } C. diphtheriae + X}{\text{Host resistance}} = \text{Malignant diphtheria}$$

Attention may first be directed toward factor "X." This represents various hypothetical elements in addition to the familiar exotoxin of *C. diphtheriae*. In attempting to solve the equation we may try various factors in the place of X.

A. *Synergistic infecting agents*—One of the factors which might replace "X" is an infective agent acting synergistically with *C. diphtheriae*, possibly more effectively (or more frequently) with the variety called gravis than with other varieties. In this connection, we may recall many observations published some decades ago in France and Germany, indicating that streptococci were suspected of contributing to the severity of diphtheria. However, in the absence of exact methods of identifying streptococci (the blood agar plate was introduced for this purpose by Schottmüller in 1903⁴² while what is now termed the beta type hemolytic streptococcus was clearly differentiated by Smith and Brown⁴³ only in 1915), we have no exact data, from the earlier period, concerning the true nature of streptococci supposed to be of pathological or epidemiological significance

in malignant diphtheritic conditions. However, several of these papers are of interest.

Barbier,⁴⁴ in 1891, recognized the existence of two clinical types of diphtheria, malignant and mild, and performed numerous experiments to discover the rôle of streptococci in the former. He concluded that streptococci (a) prepare the ground for *C. diphtheriae*, and (b) form an "association microbienne redoubtable" with this organism, resulting in a malignant infection.

Bernheim,^{45, 46} like many modern clinicians, observed cases of malignant diphtheria in which early and adequate dosage with antitoxin was of no avail. He also was convinced, by his clinical observations and laboratory studies, that streptococci were the organisms responsible, with diphtheria bacilli, for causing malignant diphtheria. Roux and Martin⁴⁷ had expressed the same opinion a little while earlier. Several other workers of the same period, including Funck⁴⁸ and Hilpert,⁴⁹ were in agreement with these ideas on the basis of both clinical and experimental observations, although there was some diversity of views on the exact mechanisms by means of which the organisms acted jointly.

Later workers likewise recognized malignant, antitoxin-refractory diphtheria as a distinctive clinical entity and many, like their predecessors, believed streptococci to act synergistically with *C. diphtheriae* in such cases. Borman^{50, 51} was one of these, contemporary with the 1931 Leeds report on gravis type bacilli. He cites many workers who, like himself, achieved laudable therapeutics with a serum ("symbioseserum") prepared by injecting animals with mixtures of streptococcal and diphtheritic antigens. Grabenhofer⁵² also was impressed with the value of such treatment. Hopmann and Panhuysen⁵³ admitted the import-

ance of streptococci in malignant diphtheria.

In this country, according to Goepp,⁵⁴ the chief cause of "difference in the virulence of diphtheria" is "the association of other pathogenic germs with the *Bacillus diphtheriae*, such as staphylococcus, streptococcus, pneumococcus, and *B. coli communis*. The most virulent cases are those in which streptococci are present." Park, Williams, and Krumwiede⁵⁵ cited two cases of antitoxin-refractory diphtheria in which there were "massive membranes of hemolytic streptococci . . . as well as diphtheria bacilli. Both cases developed a fatal streptococcus septicemia." These authors further state (p. 397) that ". . . when other pathogenic bacteria are associated with diphtheria bacilli they mutually assist one another in their attacks on the mucous membrane, the streptococci being particularly active in this respect, often opening the way for the invasion of the diphtheria bacillus into the deeper tissues or supplying needed conditions for the development of its toxin. As these septic infections due to the pyogenic cocci are in no way influenced by the diphtheria antitoxin, they frequently are the cause of the fatal termination." In malignant cases occurring at Belair, Md., and studied by the author, *the provisional clinical diagnosis in two had been septic sore throat or scarlet fever*, and large numbers of Lancefield group A,⁵⁶ actively fibrinolytic,⁵⁷ hemolytic streptococci were present. A similar case was recently (1943) observed* in the Johns Hopkins Hospital. Curiously, Lancefield group B streptococci were present, with a mitis type of *C. diphtheriae*. About 165,000 units of antitoxin had but little visible effect on the condition of the patient, who eventually recovered. Sulfathiazole therapy was insti-

* Courtesy of Dr. Russell A. Nelson, Associate in Preventive Medicine, The Johns Hopkins University.

tuted early in the course of treatment. Streptococci of group B were isolated from a child who came to autopsy in January, 1943, at Baltimore, following diphtheria with moderately developed clinical features of the malignant disease.* Mitis type diphtheria bacilli accompanied the streptococci. In other cases, of lesser malignancy, strongly fibrinolytic group A, C, and G streptococci have been found.

Cases of "hemorrhagic diphtheria" such as those described by Hannah⁵⁸ and by Frank and Hartmann⁵⁹ might represent diphtheritic infections combined with toxigenic group A streptococci in persons who, if tested, would have given positive reactions to both Dick and Schick toxins. However, the rôle of the erythrogenic toxin of streptococci, whose relationship to scarlet fever and septic sore throat has been admirably summarized by Maxcy,⁶⁰ remains to be determined for diphtheria. Degrees of malignancy in combined infections might depend on the anti-fibrinolysin or mouse-protective⁶¹ titer of the patient's blood serum. The relation of streptococci to malignant diphtheria obviously needs additional investigation.

In further consideration of synergistic agents in general, attention may be directed to the possibilities implied in Shope's discovery of the dual (virus-bacterial) etiology of severe or malignant swine influenza,⁶² and the probable synergistic or accessory rôle of bacteria (*Salmonella* and *Pasteurella*) in the virus disease hog cholera.⁶³ There is little to suggest the action of a virus in malignant diphtheria, but the possibility should not be overlooked.

B. Variations in C. diphtheriae—A second possible factor in the etiology of malignant diphtheria might be the oc-

currence of an alteration in strains of *C. diphtheriae* prevalent in a given area, such that they acquire a greatly enhanced pathogenicity. Direct evidence for such an occurrence among diphtheria bacilli, especially in nature, is lacking, although fluctuations in virulence of many other species of bacteria in the laboratory are matters of common knowledge. Indirect general evidence and theoretical support for the view that such changes may occur (in infective agents *other than C. diphtheriae*) in nature, are to be found in the publications of Frost,⁶⁴ Greenwood, Topley, *et al.*,⁶⁵ Webster,^{66, 67} and others. The sudden acquisition of a capsule, or of a somatic constituent analogous to the Vi-antigen of *Eberthella typhosa*, through the mechanism of bacterial variation, might confer greater pathogenic powers. Either occurrence is a biological possibility, but neither capsules nor *distinctive* noxious somatic substances have ever been satisfactorily demonstrated in diphtheria bacilli isolated from cases of malignant diphtheria. However, they may disappear during artificial cultivation as at present practised.

C. Special toxic properties of C. diphtheriae gravis—A third possible value for the factor X might be derived from greater toxigenicity or from toxic substances other than the exotoxin ordinarily considered characteristic of *C. diphtheriae*. As previously stated, adequate studies have shown the exotoxin of *C. diphtheriae gravis*, whether the strains tested were derived from malignant cases or from carriers, to be qualitatively identical with the exotoxin of Park 8 strains commonly used for commercial toxin, toxoid, and antitoxin production. Further, it has been shown that many *gravis* strains (when not completely atoxigenic), whether case strains or carrier strains, are rather poor toxin producers under ordinary conditions of test.

* Courtesy of Dr. John E. Gregory and Mrs. Isabelle G. Schaub, Department of Pathology and Bacteriology, School of Medicine, The Johns Hopkins University.

However, Mueller³⁸ has presented data suggesting that previous views on toxin production by gravis diphtheria bacilli may require revision. His idea is based partly on the observation by Pappenheimer and Johnson⁶⁸ that minute, but nevertheless excessive, amounts of iron interfere with good toxin production by ordinary strains of *C. diphtheriae* in various media. Mueller obtained a rough approximation of the iron content of a bit of pseudomembrane from a single case of diphtheria due to gravis type bacilli and found it relatively large. He suggested that malignant diphtheria might be due to infections with strains of *C. diphtheriae* which, unlike other strains, are capable of producing toxin in undiminished amount in spite of the excess of iron in the membrane, and that this property might be characteristic especially of gravis type bacilli. Tests *in vitro* with a single gravis strain supported his suggestion. This interesting line of experimentation could profitably be extended to a more conclusive result.

Several authors have reported a greater invasive property in gravis strains of diphtheria bacilli (presumably culturally typical strains from cases of malignant diphtheria), but the evidence on this point is far from convincing. For example, Zinnemann and Zinnemann,¹⁴ Robinson and Marshall,⁹ and Clauberg and Plenge⁶⁹ and others reported finding these organisms more frequently in the internal organs of artificially infected animals and in persons dead of diphtheria than was the case with mitis strains, but their figures lack statistical significance. In a series of autopsies on human diphtheria victims, McLeod, *et al.*,³³ never found diphtheria bacilli in the spleens or livers, but gravis strains were more frequent in lung infections than others. It was stated that in the throat there is "marked penetration (by *C. diphtheriae* gravis) into the deeper tissues,

while at the same time the surface reaction is less efficient." In the deeper tissues, exotoxin might be more readily and completely absorbed than from surface membranes. These authors suggest that the greater penetrating power (assumed) of the gravis type of organism "may very possibly be due to toxic elements of which we have not yet got sufficient knowledge." It is of interest to contrast this suggestion with the statement of Park, Williams, and Krumwiede, before cited, concerning the rôle of streptococci in facilitating the passage of diphtheria bacilli into the deeper tissues.

O'Meara^{70, 71} concluded that the gravis type of *C. diphtheriae* produces a special toxic substance ("B substance") which acts somewhat like the spreading factor of Duran-Reynals,^{71a} and also synergistically in combination with the usual exotoxin ("A substance"), the combination producing both greater extension of the toxin and also an enhanced effectiveness of the latter. McLean⁷² has found "No evidence—of any association between diffusing factor or hyaluronidase and substance B postulated by O'Meara . . ." Curiously, the so-called B substance, although spoken of as "an integral part of the exotoxin," was not sought for and demonstrated by him in the usual toxic filtrate, but in *saline extracts of bacilli* grown on Loeffler's slants. The B substance is said to combine with the few B antibodies (hypothetical) which may by good fortune be present in ordinary commercial antitoxin, thus lowering its therapeutic effectiveness. On the basis that B substance is present in diphtheria toxin, has different combining properties from those of the A substance, and varies in amount in different toxins, the writer explains at one Ehrlich's phenomenon, antigenic inadequacy of some ordinary toxoids, failure of ordinary antitoxin, Danysz's phenomenon, and some other details.

Unfortunately, the rather indefinite experiments which form the basis for the main conclusions are not fully controlled and the tabulated data do not give strong support to the statements concerning them. Because this report is among the most recent ones, and because it received rather wide notice in this country,⁷³ attempts were made in this laboratory to duplicate O'Meara's results. The attempts failed completely. Details appear elsewhere.⁷⁴ Discordant results were also obtained by Povitsky, *et al.*⁷⁵ No confirmatory reports have come to our attention so far.

3. *Alterations or defects in host resistance*—Giving, finally, some attention to the denominator of the fraction discussed in a foregoing paragraph, we may first consider the possibility that cases of malignant diphtheria develop in persons with some defect, or temporary reduction, in resistance. Zinsser, Enders, and Fothergill⁷⁶ state that they "are inclined at the moment to regard it (malignant diphtheria) as a fulminating type of infection that may, in large part, be due to host factors in the sense of variation in susceptibility." Susceptibility might easily vary significantly for several reasons such as (a) an absence of adequate natural and artificial antigenic stimuli, (b) dietary deficiencies (especially vitamin C), (c) extreme fatigue such as might attend a prolonged military effort or winter naval maneuver followed by arrival at an infected port, and (d) congenital mechanisms. It is impossible to evaluate these factors with any satisfactory degree of accuracy. We merely append references to discussions by authors who show that many of these factors might affect host resistance against infectious disease in general, or against diphtheria in particular,^{77-86a} (e) Atwater⁹⁰ suggested that antibacterial immunity might be an important factor in diphtheria, especially in children supposedly immune, who develop the

disease. The present status of antibacterial immunity has been reviewed by Frobisher and Parsons.⁹¹ The rôle of host resistance to group A streptococci as a possible synergistic agent in malignant diphtheria has received too little consideration.

By way of summary of the foregoing sections of this paper, we may say that the pathogenesis of malignant diphtheria remains obscure. Certain promising lines of investigation are indicated, especially the rôle of hemolytic streptococci in the disease, and the toxigenic properties of certain strains of *C. diphtheriae* in relation to the iron content of their environment. The rôle of antibacterial immunity also deserves further investigation.

III. DISTRIBUTION IN THE UNITED STATES OF DIPHTHERIA BACILLI HAVING THE CULTURAL PROPERTIES OF *C. DIPHTHERIAE* GRAVIS

Since the gravis type of *C. diphtheriae* has been so widely thought of as causing, or at least being closely associated with, malignant diphtheria, it is of interest to note the results of bacteriological surveys for diphtheria bacilli carried out in various places in the United States during the past decade. These have shown that carriers of gravis strains of *C. diphtheriae*, virulent or avirulent, were relatively uncommon in the country as a whole. In Baltimore, in studies made from 1933 to 1937, only 12 strains of gravis-like organisms (virulent and avirulent) were found among 237 cultures from cases, contacts, and carriers.⁸⁷ cultures from carriers in this city were often atoxigenic. Later surveys (1940) in the same area showed that little significant change had occurred in the interval. In New York City, the situation in 1940 closely paralleled that of the Baltimore area in the same year.⁸¹

More widespread sampling of the

diphtheria flora in the United States as a whole during 1939-1941 yielded similar results.⁴¹ Of 178 cultures of *C. diphtheriae* obtained from various clinical cases (none malignant so far as is known), and the immediate contacts thereof, during the fall, winter, and spring months of 1939-1940 and 1940-1941, in areas scattered from coast to coast and from Minnesota to Mississippi, only about 1 in 12 (8.4 per cent) was an organism having all or most of the principal cultural properties of *C. diphtheriae* gravis. Among the other cultures, 134 (77.5 per cent) were of the mitis or mitis-like types and 25 (14.1 per cent) of indeterminate character. Gravis strains were equally in the minority in a collection of 181 cultures from normal carriers collected during the same period in Alabama, Baltimore, New York City, and Salt Lake City. Of these cultures, 13 (7.1 per cent) were gravis or gravis-like and only 147 (81.2 per cent) mitis-like. The remaining 11.7 per cent were indeterminate. Of the whole collection of 452 cultures isolated from all sources during the 1939-1941 surveys (178 from cases and their contacts, 181 from carriers, and 93 from sources grouped as "unknown") only 38 (8.3 per cent) were gravis-like, while 361 (80.2 per cent) were mitis-like, both virulent and avirulent strains being included. If consideration be given also to indeterminate strains, the ratio of all non-gravis strains to gravis-like is about 12 to 1.

It will be noted that many cultures collected in these surveys have been referred to as gravis-like or mitis-like. These terms may be rather too inclusive. If the discussion be confined exclusively to those cultures having all of the specific characteristics of *C. diphtheriae* gravis as originally described, and to virulent strains only,* but including cultures from both "mild" and "severe" cases and car-

riers, the ratio of all non-gravis to virulent gravis would increase to about 75 to 1.

DISCUSSION AND SUMMARY

A review is given of the origin of the names *C. diphtheriae* gravis and *C. diphtheriae* mitis and of the concept that the former organism is causally related to malignant (gravis) diphtheria. Confusion arising from the adoption of varied definitions and bacteriological technics in studying these organisms, and their clinical relationships, is described.

In view of this confusion, it is here suggested that the term gravis diphtheria (or diphtheria gravis or grave diphtheria) be abandoned forthwith in favor of the term malignant diphtheria. It would also seem logical that the names of *C. diphtheriae* gravis and *C. diphtheriae* mitis be discontinued, first, as binomials not in conformity with the *International Rules of Botanical Nomenclature* and second, as bearing clinical implications which are not supported by adequate data. However, convenience and usage may dictate their continuance.

The various cultural types of *C. diphtheriae* could conveniently be designated by Roman numerals. Schemes of this sort have been advocated before.⁸⁸ A simple system is that devised by the writer in 1938,³⁴ in which the gravis type is numbered VII, the mitis type O, and indeterminate and intermediate varieties from I to VI inclusive, depending on the number of "gravis" characters possessed by them. Source and virulence should be stated separately.

A discussion of the etiology of malignant diphtheria points out that the disease is only irregularly associated with

* In the areas surveyed, there were, on the average, about two to three times as many carriers of avirulent cultures as of virulent ones.

the so-called gravis type of organism and that, in the United States at least, during the past decade, many strains of the organism have been found to be wholly atoxigenic. Reasons are mentioned for suspecting that some unknown factor or factors, either within the organism itself (development of a capsule, for example) or extraneous to, but operating in conjunction with it (such as physiological characters of the host or certain strains of hemolytic streptococci, or both), may be of determining significance in malignant diphtheria.

A brief review of the prevalence and distribution, in various parts of the United States, of virulent and avirulent diphtheria bacilli having the cultural characters of the gravis, mitis, and indeterminate types is given. It is shown that the former type was of relatively infrequent occurrence in the country as a whole at the time the studies were made.

Tropical Medicine Grants

For the 6 month period ending June 30, 1943, 12 grants amounting to \$43,680 were made by the American Foundation for Tropical Medicine, Inc., to 11 North American medical schools, a scientific journal, and the Army Medical Museum, it was reported by Dr. Jean A. Curran, executive director, at a meeting of the Executive Committee of the Board of Trustees in New York City on July 23.

These grants, made possible by contributions and pledges for the current year of \$66,600 by 21 American corporations, are being used to strengthen teaching and research programs in tropical medicine and parasitology at the various schools. The approved projects were selected by the medical committee among a number of applications.

Medical schools to receive grants during the period from April 1 to June 30 were: Cornell University Medical College, Duke University School of Medicine, University of Pennsylvania School of Medicine, and Stanford University Medical School. The *Journal of Parasitology* was also aided.

Schools of medicine to which grants

were made available during the first quarter of 1943 were: New York University College of Medicine, Tufts College Medical School, Tulane University School of Medicine, University of Manitoba Faculty of Medicine, University of Nebraska College of Medicine, and Yale University School of Medicine.

Companies which have made contributions or formal pledges of support include: Abbott Laboratories; American Cyanamid Company; Ciba Pharmaceutical Products Corp.; Firestone Plantations Company; General Foods Corporation; Hoffmann-La Roche, Inc.; The Lambert Company; Lederle Laboratories; Eli Lilly and Company; Merck & Co., Inc.; National Carbon Company; Parke, Davis and Company; E. R. Squibb & Sons; The Texas Company; United Fruit Company; William R. Warner & Company; Winthrop Chemical Company; Winthrop Products, Inc.; and John Wyeth & Brother.

The Foundation acted as the administrative agency for a special grant from the John and Mary R. Markle Foundation.

Use of Modern Laboratory Aids in the Investigation of a Typhoid Fever Outbreak

EDWARD R. SCHLESINGER, M.D., M.P.H.

*Assistant District Health Officer, New York State Department of Health,
Albany, N. Y.*

IN one section of Oswego County, which is located in the north central part of New York State, typhoid fever has remained endemic throughout the past decade, 27 cases having been reported between 1931 and 1940. This section is a dairy farming region about 80 square miles in extent and, aside from 3 villages with average populations of 1,250, is entirely rural with a density of approximately 30 persons per square mile.

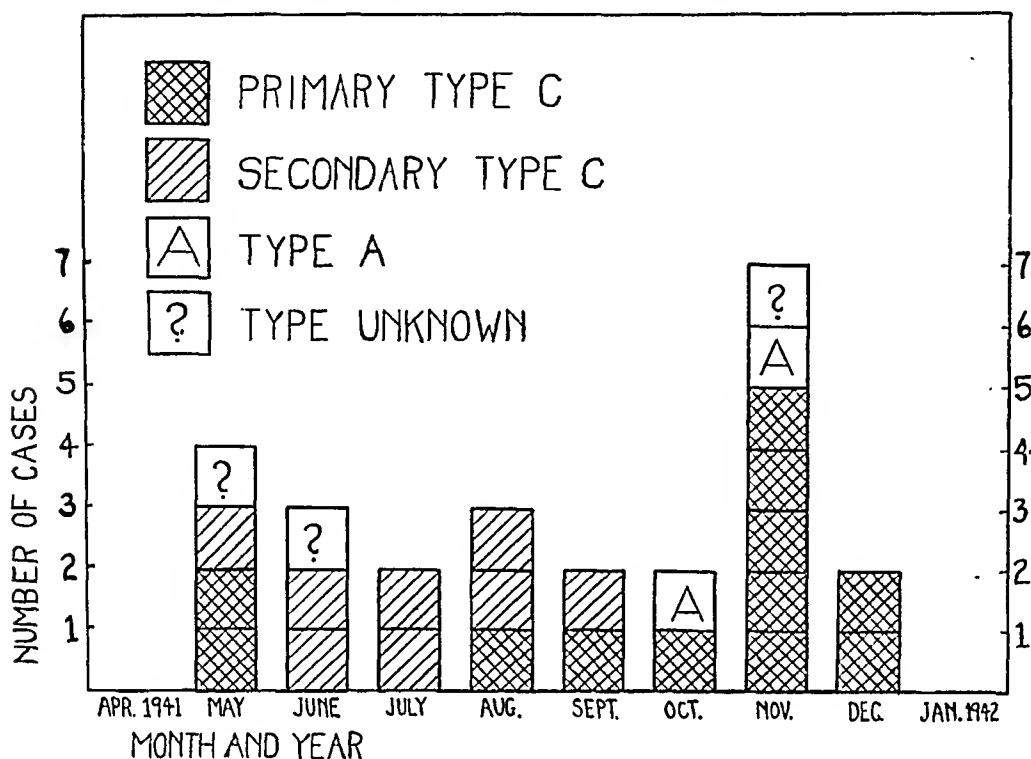

As the months of 1941 passed, it became apparent that even for this region an unusual number of cases of the disease were occurring (Chart 1). By the end of the year, 25 cases of typhoid fever had been reported, 8 of these presumably secondary familial infections. All the cases developed outside the limits of the 3 incorporated villages. There was no selection as to sex among the primary cases, 9 being male and 8 female, and the age distribution of the cases was approximately that of the population at large.

The earlier part of the investigation disclosed the apparent sources of 4 of the 17 primary cases. The first case was that of a 7 year old girl who became ill in May after she had spent week-ends during the previous 2 months at the home of her grandmother, E.O. The grandmother, who prepared food

for the child, had a history of typhoid fever and was found to be a chronic typhoid carrier. The other 3 cases were traced to a household in which M.W., a 59 year old housewife, did the cooking. A 51 year old man, related to M.W. by marriage, visited the latter's home before he developed typhoid fever in June. A neighbor's child, who also visited frequently in this home, became ill late in October. The third patient, the 2 year old granddaughter of M.W., fell ill a week after this. Although M.W. gave no history of typhoid fever, she did have recurrent attacks of colicky right upper quadrant pain and she was found to be a carrier.

Attempts to discover the source of infection in the remaining 13 primary cases proved fruitless at first. It was found that no single meal was eaten in common in more than 2 cases. Food served in the households of the cases was purchased from widely scattered sources. Milk and water used came from private supplies. In one restaurant patronized by 3 of the patients, fecal specimens submitted by the food handlers were negative for *Eberthella typhosa*. Blood sera from the food handlers revealed no Vi agglutination properties for *E. typhosa* when examined in the Division of Laboratories and Research of the New York State

CHART 1—Reported cases of typhoid fever in Oswego County according to months of onset and bacteriophage typing classified as primary and secondary familial cases

Department of Health by the method outlined by Coleman.¹

In the circumstances it was important at this stage of the investigation to determine, by bacteriophage typing, the minimum number of foci of infection involved. With this in view, typing of all available cultures, according to the method of Craigie and Yen,² was begun late in November. Ten cultures were obtained from primary cases and 2 from secondary cases in households in which a strain could no longer be isolated from the original patient. Ten of these strains were found to be type C. Type A strains were isolated from 2 of the 3 cases traced to the carrier, M.W., whose strain was also found to be type A. No culture was available from the third case associated with this carrier. The other carrier, E.O., was also found to be type A, but no culture could be

obtained from the case traced to her. In the ensuing 2 months, 2 more type C cases came to light. In another case discovered late in the course of the disease, the type was not determined because no typhoid organisms could be isolated.

The results of bacteriophage typing showed that the 2 type A carriers were not responsible for the major portion of the outbreak. The discovery of the type A cases, furthermore, confirmed the occurrence of a small outbreak unrelated to the larger mass of cases. Finally, the knowledge that at least 12 cases were type C made it likely that a single source of infection was responsible for the majority of the cases. The clue to this source was uncovered during the investigation of the last case developing in 1941.

F.E., an 18 year old boy, became ill with typhoid fever on December 18,

1941. Organisms isolated from this case belonged to type C. The boy had been employed in the preparation of mild American cheese at a small factory (hereinafter referred to simply as "the cheese factory") located at the fringe of the area in which the outbreak occurred. After questioning, it was learned that this patient had eaten curd several times at the cheese factory in the month before he became ill. He also stated that he had met several of the previous cases when they came to the cheese factory on business.

Reinvestigation of the other cases revealed that all but 2 of the primary type C cases, as well as the untyped case discovered during the course of the investigation, had eaten fresh curd obtained from the cheese factory during the 30 days prior to the onset of their disease. The 2 exceptions had had fresh cheese from the same source before they became ill. A typical story is that of R.M., a 22 year old dairy farmer. He had helped himself to curd from one of the vats on May 18, on one of the two occasions on which he delivered milk to the factory. He became ill about 8 days later. Taking the curd had been such a casual act that it had slipped his mind until he was questioned about it specifically. The only type C case without a definite history of having eaten curd or fresh cheese from the common source was a traveling salesman who died before this phase of the investigation was opened. This salesman, however, was known to have been fond of cheese and he had travelled through the area in which the outbreak occurred during the 6 weeks before the onset of his illness. Neither of the type A cases nor the third case stemming from the same type A carrier had taken any curd at all and none had any cheese that could be traced to the factory. The 11 surviving primary type C cases therefore definitely had curd or fresh cheese from

the factory whereas the type A cases as definitely did not have any from the same source.

With this evidence pointing to the products of the cheese factory as the medium of infection, it became necessary to determine whether the method of preparation of the cheese was compatible with continued survival of *E. typhosa*. Analysis of the process of manufacture revealed that the temperature of the milk or cheese was never raised above 106° F., and the acidity of the curd and fresh cheese was not materially altered from that of the original milk. The milk was delivered into vats directly from the farmers' milk cans. Rennin was stirred into the milk after the latter had been heated to 86° F. The temperature of the resulting coagulum or curd was then raised further to 106° and maintained at this level for 30 minutes. The rubbery mass remaining was finally ground and salted and placed in wooden molds. On the following day the fresh cheese was removed from the molds and allowed to stand at room temperature for about 2 weeks before it was shipped to a large factory in a neighboring county. There pasteurized American process cheese emerged as the final product. This description of the process shows that continued survival and even some growth of *E. typhosa* was possible in the curd and fresh cheese until aging caused acidification of the cheese.³

Even though the possibility of transmission of *E. typhosa* through the cheese products was demonstrated, this did not eliminate a chance association between eating the curd or cheese and the development of typhoid fever in the type C cases. Curd was a popular food locally and was to be obtained from three other cheese factories in the neighborhood as well as from the cheese factory implicated in the investigation. Nevertheless, none of these other fac-

tories was mentioned by the type C cases as the source of any cheese or curd they consumed. A small survey of 10 households in the region selected at random showed that members of only one household had eaten curd from the suspected cheese factory during the month preceding the date of questioning, contrasting sharply with the history of the type C cases. These facts strengthened the case against the cheese factory.

As a rough estimate, an average of 5 persons obtained curd from the factory daily, making a minimum of 1,200 person-exposures to possible infection over a period of 8 months. Yet only 12 cases of typhoid fever, whose probable source was the cheese factory, were reported during this period. With extensive consumption of curd, the question might be posed as to why an epidemic of far greater proportions did not occur. The chain of infection from carrier to case is a tenuous one at best. It is probable that contamination of the curd took place intermittently. Furthermore, two batches of cheese were prepared separately each day in each of two vats, so that the chance of contaminated milk reaching any given batch was only 1 in 4. Finally, it was local household practice to "can" the curd; i.e., place it in airtight jars, for periods of 4 to 8 weeks, in order to mellow it. This reduced the danger of infection to a minimum. In regard to fresh cheese, very little of this was sold at the factory, almost the entire output of the factory going into the manufacture of American process cheese.

On the evidence at hand, the following restrictions were placed upon the cheese factory with the concurrence of the owner: The sale of curd and of fresh cheese less than 6 weeks of age was to be stopped. Strict orders were to be issued to the employees of the cheese factory forbidding the consumption of curd in the factory and pro-

hibiting removal of any curd from the factory by employees or by others having business in the plant.

With these restrictions in force, a search was undertaken for a typhoid carrier in the factory. A series of 3 fecal specimens were examined from each of 9 of 10 persons employed in the factory at any time during 1941, as well as from the owner's wife and child who entered the factory almost daily. The 10th person, who could not be reached, was a 19 year old boy who had worked at the factory for only a few days. In addition, Vi antibody studies were performed on blood specimens obtained from the owner and the 2 steadily employed workers. The results of all these examinations were negative. A sanitary survey of the water supply serving the factory evidenced no permanent source of human pollution within dangerous distances. Bacteriological examination of the water showed no coliform organisms. It was felt that the supply should be of safe sanitary quality. In view of these negative findings, contamination of the curd at the factory was therefore extremely unlikely.

The search for a typhoid carrier among the dairy farmers supplying the cheese factory concluded the investigation. Review of the factory records revealed that 242 farmers had shipped milk to the factory at some time during the last 9 months of 1941. Of these, 64 had delivered milk regularly during the entire period. Prominent among these 64 was a 57 year old farm housewife, N.M., who had been under suspicion on a previous occasion as a possible typhoid carrier.

N.M., whose chores included milking the cows, first came under attention in 1935 when 7 persons on a neighboring farm developed typhoid fever. She had had typhoid in 1918, following which she had suffered for 6 months from attacks of epigastric pain radiating to

the right shoulder. The first fecal specimen obtained from her in 1935 revealed the presence of *E. typhosa*, but 9 subsequent specimens were negative. Milk from her farm was first delivered to the cheese factory in October and November, 1940. No further deliveries were made until April 1, 1941, 5 weeks before the onset of the first case traced to the cheese factory. Because of this epidemiological evidence, N.M. was strongly suspected as the source of the 1941 outbreak. A blood specimen secured early in 1942 showing the presence of Vi antibody in a titer of 1:80 further strengthened this suspicion. However, 18 fecal specimens submitted by her between February 17 and August 31, 1942, were negative for typhoid bacilli, despite the fact that 9 specimens were authenticated by the use of lycopodium spore capsules prior to submission of the specimens and liquid specimens were obtained by the administration of magnesium sulfate. Finally she was hospitalized. A series of 3 biliary and fecal specimens secured on successive days, each time following the injection of magnesium sulfate via duodenal tube, contained *E. typhosa*. The type of the organisms could not be determined with the bacteriophage preparations available but it was definitely not type C. Therefore, despite the overwhelming epidemiological evidence, N.M. was not the source of this outbreak. While N.M.'s status was being settled, 20 other dairy farmers were examined with negative results.

For the first 8 months of 1942, Oswego County was free of typhoid fever. In September, 2 new type C cases were reported. Both of these had secured curd from the factory during the month before the onset of their illness. Apparently the constant turnover in help at the factory had made it difficult for the owner to maintain the restrictions upon which he had agreed.

Another case of typhoid fever, occur-

ring in one of the nearby villages in the month of September, 1942, led to the discovery of the carrier presumably responsible for the outbreak. This 30 year old patient, whose organisms were resistant to typing, had never eaten curd and he disliked cheese. However, he had spent 3 weeks on the farm of one of the 64 dairy farmers, G.W., 47 years of age, who had delivered milk to the cheese factory during the entire period of the outbreak. This visit to the farm had terminated 6 weeks before the onset of the patient's illness, but the patient had paid another short visit 3 weeks later. Five fecal specimens were submitted by the dairy farmer and all contained typhoid bacilli which fell into type C. G.W. had no history of typhoid fever and no complaints suggestive of cholecystic disease. The absence of a history of the ingestion by the carrier of any products of the cheese factory eliminated the possibility of a passive carrier state. Milk deliveries to the cheese factory from his farm had begun in May, 1940. No further cases of typhoid fever have been traced to the cheese factory since September, 1942, a period of 11 months at the time of writing. Milk deliveries to the cheese factory have been stopped from the farms of the 2 carriers.

DISCUSSION

Although a number of epidemics of typhoid fever due to contaminated cheese have been reported,^{4, 5} the present outbreak has several features of unusual interest. In the first place, the main body of cases were spread over a period of 8 months, with 2 more cases 9 months later, indicating repeated contamination of the milk supply of the cheese factory. In the second place, the majority of the cases became infected by eating small amounts of curd at the factory, usually when they entered the factory on business. Although the curd was used extensively in the

neighborhood, very little of it was consumed in a fresh state away from the factory. Finally, 4 cases occurring contemporaneously with those caused by ingestion of cheese or curd were found to be unrelated to the latter.

The use of more recently developed laboratory procedures provided valuable assistance during the course of the investigation. Bacteriophage typing confirmed the existence of two components unrelated to the main outbreak. It ruled out the type A typhoid carriers as the cause of the outbreak and later, when 2 carriers were found among the dairy farmers supplying the cheese factory, typing definitely eliminated one of them as the ultimate source of the outbreak and indicated the probable responsibility of the other. The utilization of Vi antibody studies permitted a more certain exclusion of the food handlers in the restaurant and cheese factory as typhoid carriers. The presence of Vi antibody in the blood from N.M. encouraged continued search for typhoid bacilli in her fecal specimens, despite the fact that a total of 18 specimens, several authenticated by the use of lycopodium spores, were negative. The combined Vi antibody studies and bacteriophage typing relegated N.M. to her proper place as an incidental carrier unrelated to the causation of the outbreak.

SUMMARY AND CONCLUSIONS

1. An outbreak of 27 cases of typhoid fever is described, 23 of which were probably due to the ingestion of curd or fresh cheese at a local factory or were secondary to such cases.

The cases occurred over a period of 17 months.

2. Bacteriophage typing separated the type C cases, due to the contaminated curd and cheese, from type A cases, traced to food prepared by 2 type A typhoid carriers.

3. Two typhoid carriers were found among the dairy farmers supplying the cheese factory. Typing showed one to be type C and eliminated the other as the possible source of the outbreak; despite the fact that epidemiological evidence alone pointed more forcefully to the latter as the carrier responsible for the outbreak.

NOTE: We wish to express our appreciation to the following members of the Staff of the New York State Department of Health: Dr. Edward B. Bukowski, Acting District State Health Officer, for his supervision and encouragement throughout the investigation and for his own investigation of the first case of typhoid fever to occur in 1941, resulting in the discovery of the typhoid carrier, E.O., as the source of the case; Marion B. Coleman of the Division of Laboratories and Research for the performance of the Vi antibody studies and bacteriophage typing, the results of which are given in the body of the paper; and Herbert H. Wagenhals, District Sanitary Engineer, for the sanitary survey of the water supply serving the cheese factory.

Epidemic Diarrhea of the New-born: A Report of Two Outbreaks

PAUL A. LEMBCKE, M.D., JAMES J. QUINLIVAN, M.D., AND
NORRIS G. ORCHARD, M.D.

*District Health Officer, and Assistant District Health Officer, New York State
Department of Health, Rochester, N. Y.; and Deputy Health Officer,
Rochester, N. Y.*

TWO outbreaks of diarrhea of new-born infants occurred in a hospital in Rochester, N. Y., within a 4 month period. In the first outbreak the disease seemed to be transmitted chiefly by contaminated rubber nipples and formulae and to a lesser extent by indirect contact; in the second it was apparently transmitted by faulty maternal breast technic. Both outbreaks promptly came to an end following control measures based upon studies of the mode of transmission.

METHODS OF INVESTIGATION

The investigation was conducted by representatives of the Rochester Health Bureau and the New York State Department of Health, with the coöperation of the hospital staff. Data for all infants, sick and well, were transcribed from hospital records to epidemiological record forms upon which were entered name, address, date of birth, sex, color, nursery or nurseries occupied, outcome, and daily observations of weight, body temperature, feeding, stools, special procedures, and unusual occurrences. To provide a base-line of normalcy, these records were obtained for pre- and post-epidemic as well as the epidemic periods. The methods employed by the hospital for recognition of cases, isolation, general nursery technic, and formula preparation were

studied in detail, and samples of feces and of nipples, bottles, and formula were subjected to bacteriological examination.

FIRST OUTBREAK: APRIL-MAY, 1942

An investigation was begun May 1, when through following up a death certificate it was discovered that a number of cases of diarrhea, some fatal, had occurred among infants in the hospital during the latter part of April.

Nature of the illness—Severe cases were characterized by frequent loose greenish stools, reddening of the buttocks, mild fever, dehydration, and loss of weight. This was the type of case generally conceded by hospital staff physicians to represent clear-cut diarrhea of the new-born. There were 28 such cases, in which group all of the 3 fatalities occurred. One death was of an infant with a cephalic deformity compatible with life, one in an infant with cerebral hemorrhage, and one in an infant born prematurely but of normal birth weight.

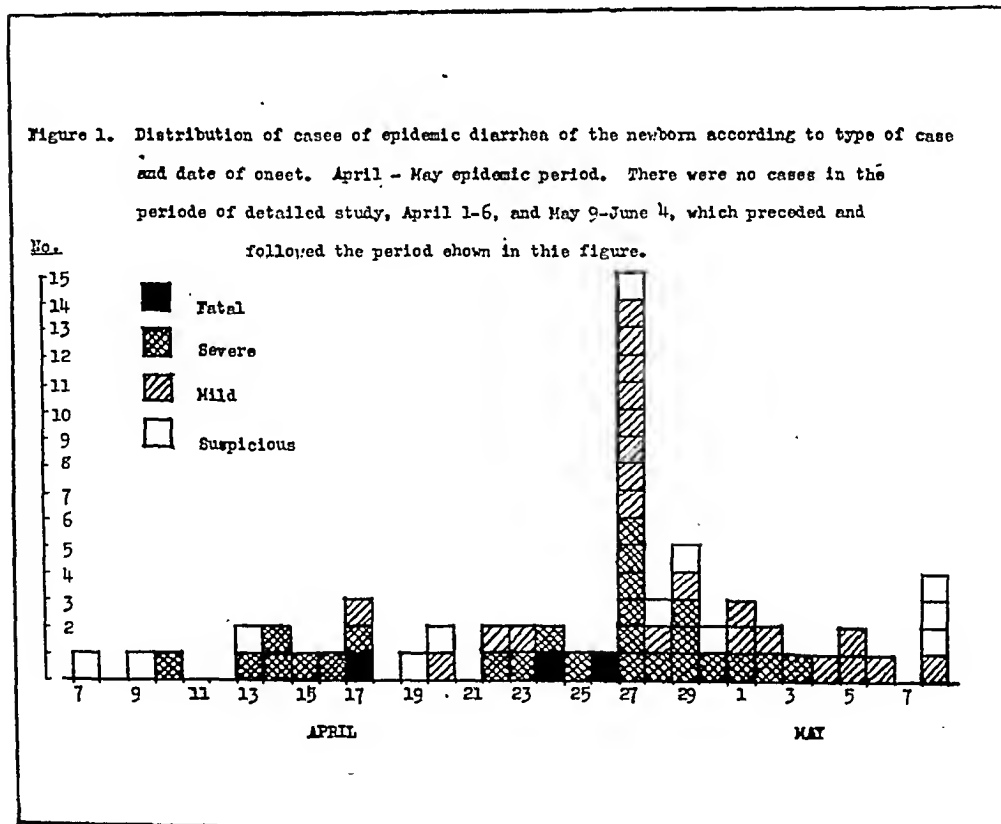

Twenty-two infants which presented signs and symptoms only slightly less marked were considered by the investigators to be definite cases also, making a total of 50 in this outbreak. Twelve others with still milder signs were classified as suspicious cases, and an additional 21 who showed only slight

deviations from normal, such as a few green stools or a temporary increase in number, were classified as probably normal. One hundred and thirty-five infants were considered to be normal. Thus, as in many other diseases, there was a gradation from normal to very severe which, in the absence of a means of laboratory confirmation, presented a very difficult problem in diagnosis.

Diagnosis—From the epidemiological standpoint it made little difference whether one diagnosed as epidemic diarrhea of the new-born only the 28 severe cases, or included the 22 definite but milder cases, since the distribution of the two types was similar with respect to date of onset, nursery of occurrence, feeding history, etc. From the standpoint of control, however, the diagnosis and segregation of the milder cases was of great importance since they also were presumably infectious. This

may have been true of the suspicious cases as well. As an aid in diagnosis a rigid classification was set up and adhered to. The essence of it was that if an infant had more than one loose stool in one day he was considered as suspicious, and if loose stools persisted for two or more days he was classified as a case.

Chronology—Figure 1 shows the distribution of severe, mild, and suspicious cases according to date of onset. The probably normal infants are not shown because they present no chronological relationship to the epidemic and are considered to represent only simple biologic variations from the norm. The outbreak began about April 7 and ended May 8. A marked peak occurred on April 27 when 14 definite cases occurred. The distribution of suspicious cases does not follow closely the other two types except that

their occurrence was limited to the epidemic period. Subsequent tables omit suspicious cases and group the severe and mild cases together.

H2-B 5 days, and in H3 5 days after these nurseries were opened.

Relationship to type of feeding—It was customary in this hospital to give

TABLE 1

* Still open June 4

Nurseries affected—Table 1 shows the distribution of infants and cases according to nursery. The number of infants for nurseries H1-A and H2-A is made up of those infants in such nurseries on April 1 and those admitted subsequently. A few infants who died or left the hospital shortly after birth are excluded from the figures. Fifty cases of diarrhea occurred among 178 infants at risk April 1 to May 5, a rate of 28.1 per cent. The similar attack rates in nurseries H1-A and H2-A suggests that the factor or factors producing the illness were operating with approximately equal force in each. The first definite case occurred in H2-A on April 10 and in H1-A on April 14. The chronological distribution of cases was approximately the same in each of these nurseries and in each instance the peak incidence fell on April 27. The first case occurred in

routinely only 5 per cent lactose for the first 2 or 3 days of life; subsequently most infants were put to breast and given supplementary feedings of whole or evaporated milk formula. Thus every infant had some exposure to the possibility of infection by contaminated nipples, bottles, and lactose or formula. A small number were never put to breast, and a very small number never received any formula.

Table 2 shows the attack rate according to type of feeding for 177 infants for whom data are available at risk during the epidemic period. Although the numbers on which these rates are based are small, there appears to be a definite trend toward increased risk of attack as the amount of artificial feeding increases and breast feeding decreases. There is no statistically significant difference between evaporated and whole milk, either alone or

TABLE 2
*Attack Rates According to Type of Feeding
April-May Outbreak*

Type of Feeding	No. of Infants	No. Ill	Per cent Ill

Whole milk only	10	5	50.0
Other (dry milk, etc.)	6	5	83.3
Totals	177	49	27.7

in conjunction with breast milk. Grouping the types of feeding it is found that, whereas only 21.5 per cent of 144 infants receiving breast milk and supplement became ill, 54.5 per cent of the 33 receiving formula alone became ill. This difference, which is statistically significant, emphasizes the association between risk of attack and type of feeding. Similarly, only 16, or 11.1 per cent, of infants receiving some breast feeding developed severe cases while 12, or 36.4 per cent, of those receiving only formula became severe cases. On this evidence alone, however, it is impossible to state whether breast milk confers a protective effect or whether formula carries increased risk of infection.

Totals	178	50	28.1

* Grouped to nearest indicated weight

Relationship to birth weight—Table 3 shows that in this outbreak overweight as well as underweight infants apparently were somewhat more susceptible than those of normal birth weight.

Sex—There were 28 cases in males, 22 in females. All 3 deaths occurred in males.

Age—In the absence of knowledge of the date of effective exposure it is impossible to fix the incubation period. Table 4 shows the distribution of cases according to the day following birth in which first symptoms occurred. The median case fell on the 5th day. The most interesting feature of this table is the indication that the incubation period may be as short as 24 hours.

The brevity of this period suggests an infectious or toxic agent received by ingestion, paralleling the experience with gastroenteritis in older children and adults.

Mode of transmission—The medical histories of the mothers and the causes of illness among nurses absent from duty or cared for by the institutional medical service were reviewed without gaining any information as to the manner in which the agent responsible for the outbreak was originally introduced.

There was little opportunity for direct contact, the bassinets being kept in cubicles with intervening partitions 2 feet in height. Breast-fed infants were conveyed to mothers in a large carrier, a partition 10 inches high separating the infants. Although in these circumstances respiratory spray from one infant might reach another, none presented any respiratory illnesses which would forcibly eject such a spray for a great distance. Transmission of infection by equipment did not seem likely since individual tubs, toilet articles, and thermometers were used, infants were diapered in their own bassinets, and a clean drape was placed on the scale before weighing each infant.

Some degree of transmission through breaks in nursing technic seemed quite possible although the evidence was indirect. In the previous year the hospital averaged about 100 deliveries

per month, but the phenomenal rise in the birth rate in 1942 increased this rate to more than 150 per month. Coincidental with the increase there was difficulty in securing sufficient and well trained nurses. Prior to and in the early weeks of the epidemic the nurseries were understaffed, it being reported that on occasion a single nurse might be responsible for the care of 30 or more infants for a period of hours, and it was indeed observed that one nurse would frequently be caring for as many as 20 infants at one time. The ratios of infants to nurses far exceeded minimum standards. In the large nursery, H2, bassinets were in two adjoining rooms, yet a sink was provided in only one. In the several nurseries nurses were occasionally observed to wash their hands only perfunctorily after diapering an infant and to use cold or tepid water and very little soap. Until May 2 or 3 the routine provided for diapering infants before feeding, thus increasing the risk of transmission of infection if a break in technic occurred.

As reported previously,¹ rubber nipples have been suspected as a vehicle of infection. In this hospital they were washed in the nursery after use, placed in a vessel of boiling water for a period of 3 to 15 minutes, removed with sterile forceps, and placed in a sterile covered jar until the time of the next feeding when they were applied to the bottles by hand by the nursery nurse. No precautions were taken to insure complete submersion of nipples in the water. The period of boiling seemed rather short in view of a finding some weeks previously by the obstetrical supervising nurse that satisfactory bacteriological results were not obtained with less than a 20 minute period.

The possibility of transmission through contaminated formula¹ was seriously considered in view of the

nearly simultaneous onset of the epidemic in the two nurseries operating in April, the explosive occurrence of cases on April 27, and the similar course of the epidemic in both nurseries. Formula was prepared in a room which was well equipped but obviously too small for the purpose. Bottles were boiled for 15 minutes before being filled. Whole milk formula, water and 5 per cent lactose solution, were reported to be boiled prior to filling bottles. Evaporated milk was boiled in the can, added to Karo and boiled water in a graduate, and the mixture poured into bottles. Powdered milk formulae were made with boiled water but the resultant mixture was not boiled. After the nursing bottles were filled a boiled rubber cap was applied. Some were sent to the nurseries to be refrigerated until needed and some, together with additional formula held in reserve in quart bottles, were stored in the formula room refrigerator. Failure to defrost often and frequent opening of the refrigerators cast some doubt as to the adequacy of refrigeration. These preparations were carried out by one or more student dietitians and a maid, under supervision of the chief dietitian. Other demands on the time of the latter were so great that close supervision was not maintained.

Nipples and formula which were ready for use by infants were secured at random under sterile precautions, and examined by the Rochester Health Bureau Laboratories and the Division of Laboratories and Research, New York State Department of Health. Total bacteria counts were obtained for nipples by swabbing outer and inner surfaces with a sterile swab moistened in buffered dilution water, reimmersing the swab in 2 ml. of the water and then plating out 1 ml. Counts were obtained for formulae by the standard plate count method for milk examination.

Table 5 shows the number of samples examined and the maximum, median, and minimum counts for the indicated day. Caution must be used in reading the results for formula examination; on May 5 the count next highest to the one of 470,000 was only 200; on May 10 the count next highest to the one of 540,000 was only 200, and on May 12 the count next highest to the one of 30,000 was only 600. A definite reduction in the counts for nipples is observed beginning with reorganization of the formula room May 5. Improvement in formula counts is not so noticeable until May 11. Organisms of the coliform group, indicating contamination presumably of fecal origin, were found on April 30 in 2 samples of formula, May 5 in 1 and May 12 in 1. They were found May 1 on 2 nipples, May 4 on 7, and May 12 on 3.

Diagnostic laboratory findings—53 fecal specimens from 17 sick infants were submitted to the Division of Laboratories and Research for examination. None of the bacillary incitants of enteric disease nor any other microorganisms of recognized diagnostic significance were found. Marion

B. Coleman of the Division of Laboratories and Research, New York State Department of Health, kindly repeated the work described in a previous communication.¹ Two or more baby Swiss mice were inoculated intraperitoneally with ether-treated portions of each specimen and in addition single fecal specimens from each of 10 infants in a second hospital in Rochester were similarly examined as controls. The results are summarized in Table 6.

Grouping the severe and mild cases, it is found that 39 per cent of inoculated mice died, and grouping the normal controls, only 11 per cent died. Or, considering infants whose feces contained some principle capable of killing mice, 70 per cent of the severely ill possessed this property; while 53 per cent of the severe and mild cases together, and only 27 per cent of the control cases had this property. These data have been so presented as to minimize the apparent difference between sick and well infants and taken as they stand may not appear conclusive. However, taking into account the factors mentioned in the footnotes to Table 6, particularly the prolonged incubation period in fatal instances in

TABLE 6

* Of the 8 deaths upon which this percentage is based, 7 occurred among mice inoculated with specimens from a single infant.

† The 3 deaths upon which this percentage is based occurred 6, 7, and 15 days following inoculation, in comparison with a usual period of 1-4 days in mice dying in the other groups. In each instance a mouse inoculated with a portion of the same specimen survived.

NOTE: 4 infants in the "severe" group were receiving sulfaguanidine. For 2 of these all mice survived; for 2 others 13 of 28 mice died.

the control group, it appears justifiable to interpret these findings as showing that some agent lethal for mice is frequently present in feces of infants suffering from diarrhea of the new-born. Unfortunately, this agent has not been identified. The relatively infrequent association of this effect with feces of mildly ill infants may have been due to improper diagnosis or a lesser concentration of the agent in the feces, or both.

Control measures—Prior to the investigation, control measures had consisted of instituting gown technic on April 28, isolating very ill infants by transfer to the pediatric nursery, vacating and washing nursery H1-A, closing H2-A to admissions, and establishing H2-B for new admissions on the dates indicated in Table 1. Mild and suspicious cases were not usually recognized and isolated, and since there was no one person responsible for detecting and ordering isolation of cases it was not uncommon for a day or two to elapse between onset and isolation of a recognized case. The measures described did not seem conspicuously successful, although one cannot state with certainty what the actual outcome would have been had no additional measures been imposed.

On May 1 arrangements were made for the detection of ill and suspiciously ill infants according to the criteria described in the section on diagnosis. Being an attempt to determine infectiousness and based primarily upon feces rather than clinical condition, this standard resulted in the classification of some infants as definite or suspicious cases at a time when their general condition seemed satisfactory to the clinicians. Considerable friendly dispute with clinicians arose thereby, but the standard was rigidly adhered to and all such infants were required to be isolated.

Specific recommendations were made for preparation of nipples and formula in the central formula room. Formula for a 24 hour period was to be made up and subsequently boiled before filling autoclaved bottles; nipples boiled 30 minutes while completely submerged were to be applied to the bottles in a sterile field using aseptic technic; nipples were to be covered with an autoclaved metal cap; and the whole was to be immediately refrigerated.

Assuming that these recommendations would be carried out immediately, a new nursery, H3, was opened May 1 to receive newly-born infants who would have had no contact with others

and who would receive sterile food and drink. Well infants in other nurseries were to remain where they were unless they became ill and required transfer to the pediatric nursery, or until they were discharged home. Establishing H3 was not a successful venture; one-third of the 15 infants admitted within the next 5 days became ill, beginning May 4. The manner in which the disease was introduced is not known, but from a study of Table 5, it would seem reasonable to attribute it to failure to sterilize nipples, and possibly formula, until May 5. On the latter date the formula room was placed in charge of a nurse who taught bacteriology, with immediate improvement in bacteriological results. Under her direction the new procedure was routinized and was subsequently returned to the dietitians. Other control measures provided that infants be diapered after rather than prior to feeding, and placed emphasis on careful handwashing. A larger nursing staff and rearrangement of one of the nurseries were urged.

Having attained satisfactory technic in the formula room, new nurseries, H1-B and H2-Prem. were opened May 5 (see Table 1). No cases occurred among infants born on this date or thereafter for a period of daily study extending through June 4. The cessation of the epidemic following these measures may have been due to prompt recognition and isolation of cases, or improvement in nursing technic, or proper sterilization of nipples and formula, or some combination thereof.

SECOND OUTBREAK: JULY, 1942

After June 4 daily observations were discontinued in the expectation that satisfactory conditions would continue, but on July 22 the hospital reported the recent occurrence of a number of cases of diarrhea. An investigation undertaken in the manner previously described revealed that the nurseries

had remained free of diarrhea from June 4 until July 8 and 9 when 3 rather mild cases occurred in H1 nursery. These were not isolated but the outbreak subsided spontaneously. On July 17 an infant in the H1 nursery developed loose stools and was not isolated but, following this, cases began to appear as shown in Table 7.

The majority of these cases were quite mild, resembling those classified as mild in the April-May outbreak, and there were no deaths. None of the bacillary incitants of enteric disease or any other microorganisms of recognized diagnostic significance were isolated from 11 fecal specimens from 6 sick infants. Twenty-two mice were injected as described previously. One mouse inoculated with material from the most severe case died 8 days later; the others remained well and showed no abnormalities when chloroformed and autopsied 3 or 4 weeks later.

The rather explosive occurrence of cases July 20, 21, and 22, and the similar attack rates of 24 per cent in H1, and 32 per cent in H2 nurseries suggested a common source of infection, probably nipples or formula. In

partial support of this hypothesis it was found that of 8 nipples prepared July 22, one showed a total count of more than 160,000 and others counts of 56,000, 8,000, and 4,400. These were chiefly spore-forming organisms, probably *Bacillus subtilis*. Of 8 samples of formula, only one had a high count, 29,000; this and two other samples yielded *B. subtilis*. Perhaps as a result of the attention focused on the formula room, results were uniformly good July 23 and after.

When feeding histories were analyzed, however, it was difficult to support the hypothesis of spread by contaminated nipples and formula. Table 8 shows attack rates according to feeding history for infants in the hospital July 18-23. Section A of the table classifies infants according to the type of feeding beginning from birth and indicates that in this outbreak breast feeding carried a great risk of attack. This finding was so contrary to what was expected that it was thought possible a number of infants classified in Section A as breast-fed might have gone to breast for only a few days in the preëpidemic period and subsequently received formula as a supplement or alone during the period beginning with the onset of the first case on July 17. Section B of Table 8 classifies infants according to the type of feeding in the

period July 17-20. This analysis brought out even more strikingly the risk of breast feeding and the safety of artificial feeding under the conditions prevailing, and directed attention to breast-feeding technic.

It was found that under the stress of a shortage of nurses the practice had developed in each of the two nurseries of providing a single breast tray containing a vessel of 4 per cent boric acid and one of cotton pledgets. Infants were diapered, etc., prior to being taken to the mother for breast feeding. The nurses would then dip cotton pledgets in the boric acid and with the fingers squeeze the excess fluid back into the vessel. Infants were carried to the mothers, the pledgets were used to cleanse the nipples and the infants were then put to breast. The cotton pledgets as such did not fall under suspicion because a fresh supply was received daily from the carefully controlled central autoclave. There remained the possibility that a nurse might contaminate the boric acid solution with her fingers and if the organisms survived for even a short time contamination could be transmitted to the nipples of a number of mothers and thus to their infants.

F. Wellington Gilcreas of the Division of Laboratories and Research, New York State Department of Health,

prepared suspensions of *Escherichia coli*, *Staphylococcus aureus*, and *Streptococcus faecalis*, and inoculated them into 4 per cent boric acid and into distilled water. At the intervals indicated in Table 9, portions were removed and the average count per ml. determined. With both 1:1,000 and 1:100,000 dilutions there were too many colonies to count in case of all three cultures which were inoculated into distilled water. In 4 per cent boric acid *S. aureus* failed entirely to survive and only a few organisms of the coliform group survived, but *S. faecalis* was not affected. It is not held that *S. faecalis* was the etiologic agent in this outbreak but it does seem reasonable to assume that some type of organism capable of surviving for some time in 4 per cent boric acid was at fault.

As in the previous outbreak sick infants were promptly isolated in a separate nursery (H3). By July 25 the probable mode of transmission was sufficiently appreciated to lead to the recommendation that breast technic be revised. Effective control seems to have been attained shortly thereafter by the use of forceps to handle the pledget, although one case occurred in a formula-fed infant July 29, and one in a breast-fed infant August 3. The technic was later revised to provide for

individual pledgets on wooden applicators. No further cases were recognized during a period of close observation concluded August 24.

In explanation of the approximately simultaneous outbreak in the two nurseries is the fact that shifts of nurses occurred at a time and under conditions which would permit the development of cases by the spread of infectious material from the case developing July 17. The greater incidence of cases among those receiving breast milk and lactose solution than among those receiving breast milk and formula is perhaps due to the fact that on the average the former were put to breast more often, and without fail during the night when lapses in technic were more likely to have occurred.

SUMMARY

1. An epidemic of diarrhea of the newborn consisting of 22 mild and 28 severe cases, with 3 deaths, occurred in a Rochester, N. Y., hospital in April and May, 1942.

2. The etiologic agent was not determined. Evidence was secured that the feces of sick infants contain an agent fatal to baby Swiss mice in significantly higher proportion than feces of well infants.

3. The incubation period was observed to be as short as 24 hours in 3 cases. The disease tended to select infants below and above normal birth weight. Two of the 3 deaths occurred in infants with birth injury or congenital abnormality.

4. The incidence of illness was significantly greater and more severe among infants artificially fed than among the breast-fed.

5. Opportunity for transmission of infection was afforded by contamination of nipples and formula. Delay and inadequacy in recognition and isolation of cases may have been contributory. The epidemic came to a close following correction of these faults.

6. A second epidemic of diarrhea of the new-born consisting of 21 mild, non-fatal cases occurred in the same hospital in July, 1942.

7. Illness was limited almost exclusively to breast-fed infants. Opportunity for transmission of infection was afforded by probable contamination of a common vessel of 4 per cent boric acid used to cleanse the breasts. The epidemic came to a close following correction of this fault.

CONCLUSIONS

Epidemic diarrhea of the new-born is a disease in which the unidentified etiological agent is present in the intestinal and possibly oral discharges of sick infants. The occasional introduction of the disease into a nursery, probably from an inapparent adult source,² is difficult to prevent. If routine technics permit transfer of infectious discharges through contamination of nipples, formula, and breasts, or indirect transmission by attendants, an

epidemic will occur when the infection is introduced. Insufficient or inadequately trained personnel and faulty equipment contribute to the opportunities for transfer of secretions and excretions. Prevention and control depend upon laboratory controlled methods of sterilizing nipples and formula, good nursing technic, prompt recognition, reporting and isolation of cases, and immediate epidemiological investigation by a competent person, which ordinarily will mean by an epidemiologist in the health department.

THE WAGNER-MURRAY BILL

THIS bill makes physicians conscious that the heretofore vague shadow of socialized medicine is becoming foreshortened and of some substance. They realize that if this bill were enacted into law the practice of medicine would be changed, and quite definitely changed, for it would place under government auspices medical and hospital care for the great majority of the population of the United States. Funds for the service would be provided through pay roll deductions as a part of the general social security program. Organization would be on a federal basis, physicians being employed through the Surgeon General of the U. S. Public Health Service. Hospital and auxiliary care would be under the same direction.

There would be an Advisory Council, appointed by the Surgeon General from nominations submitted by medical and other organizations. In the program itself, a given physician would participate or not as he chose; he might participate on a fee basis or per capita, or on part- or full-time salary. A beneficiary would have the right to choose his physician from among those participating. The physician would retain the right to accept or not accept a given patient, unless perhaps that physician were employed on a salary basis.

The reaction of most well established physicians in opposition to this bill has been definite, even vehement and bitter in some quarters. An editorial in the *Journal of the American Medical Association* (June 26, 1943) reviews the genesis of the bill, pauses to point out that while "spell of sickness," used in the bill, is poor English, it is at the same time evidence that the medical profession was not consulted as to medical provisions; uses the word "gauleiter" as descriptive of the position of authority proposed for the Surgeon General of the Public Health Service, presents some "quotes" from the bill indicating the extent of that power, and ends by quoting from the *Chicago Daily News* to the general effect that the worker's zeal for social security will be dampened by ever-mounting pay roll deductions inherent in such schemes.

Another editorial in the September 4 issue of the same *Journal* summarizes the June 26 editorial, even to the "gauleiter" term, quotes further from news-

paper editorials unfavorable to the bill, takes cognizance of an editorial, not pro-organized medicine in character, in *Medical Care* (August, 1943), and calls upon the medical profession to prove to Senator Wagner and his colleagues, "by a complete and forceful presentation of the points of view of American Medicine, how far from perfect is the measure (the Wagner-Murray bill) he has proposed."

Another evidence of opposition to the bill is to be found in a pamphlet released and distributed to physicians by the National Physicians' Committee for the Extension of Medical Service. This committee's views on medical care have in the past appeared to reflect the opinions of leaders of organized medicine, and the pamphlet itself tends to emphasize the probable and possible ills and, one cannot help but feel, some imaginary ills that physicians and the public would suffer if the medical service proposals of the Wagner-Murray bill are enacted into law. In contrast, the Committee of Physicians for the Improvement of Medical Care, Inc., which has seemed generally inclined toward government-arranged medical care and does not see eye to eye with organized medicine nor with the National Physicians' Committee, has issued a statement congratulating Senator Wagner on presenting the bill, designates it as a framework and a basis for discussion, and expresses the hope that the Committee of Physicians "will be given an opportunity to participate in the discussions of the bill and to offer its advice and suggestions." An editorial in *Medical Care* has been referred to above.

Thus, to date, there have been only preliminary skirmishes. Opponents of the bill, for the moment, appear to be the more active. Possibly this is because those who favor the medical service proposals count upon the popularity of unemployment benefits and pensions to overcome opposition to the proposals for socialized medicine, the latter being only part of the broad program of social security which this bill is designed to provide. No one person may announce for the American Public Health Association a policy or attitude in regard to this proposed legislation. Only the Governing Council may make a statement of that sort. This much, however, may be said editorially. Most of those who are not emotionally prejudiced in favor of or against this bill see in it provisions that seem reasonable and necessary and implications that may be dangerous. So far as concerns the medical service element, neither its virtues nor its vices would in practice be so superlative as proponents and opponents respectively prophesy. As regards quality and quantity of medical care, some of the present disabilities and deficiencies would perhaps disappear but, at the same time, much that is fine might too disappear. Thus, though care would be more nearly assured to the population at large, that care would inevitably be burdened with the by-products of red tape, perfunctoriness and mediocrity inherent in most civil services, and possibly with some politics.

It is the general implications of the bill, more than the specific medical elements, that cause apprehension among those who attempt to view the matter dispassionately, in that this legislation would introduce socialization on a vast scale, and contemplates an entirely federal administration with complete disregard of state boundaries and sovereignty. It would thus commit the American people to an entirely new order of life, one which heretofore has been experimented with only in a superficial and dilettante fashion. Maybe the ends justify the means, maybe the complexity of the social and economic order of the United States makes the bill necessary and wise. One might wish, however, even though doubting the success of a voluntary scheme, to see some experimentation with less compulsion as to who must be beneficiaries; equally, while one might suspect

that a federally administered medical service would be more effective than the average state administered service, it would seem precipitate, without trial, to exclude state participation so completely as this bill contemplates. Federal-state coöperation has worked admirably in public health matters. In any event, one needs carefully to consider the price, other than financial, that would be paid for the security that this bill is designed to provide.

Whether or not the Wagner-Murray bill is enacted into law, it seems likely that a bill providing medical service of some sort and extent will be passed by the Congress before very long. If this is the case, it would be the part of wisdom for those who are interested in preserving the fine traditions of private medical practice and of private medical research and medical education, to offer some alternative plan or scheme which may do less violence to independent medicine on the one hand and which at the same time would insure to the average citizen a high grade of medical care. Continued blind and hair-splitting resistance, by physicians, to any and all proposals for some degree of public medical service will but tend to strengthen the contention of those who insist that the medical profession is unreasonable in its attitude, selfish in its interests, and lacking in constructive leadership. Convinced of this, the public may give support to legislation detrimental to real progress in medical science and not to the best interest of the people of the United States.

ON THE NEED FOR BASIC KNOWLEDGE

IN recent years and under the stimulation of a somewhat aggressive pedagogical philosophy, there has arisen a tendency to believe that if one knows how to teach or to analyze or administer, then a thorough knowledge of the thing to be taught or analyzed or administered is of but secondary importance.

Out of such a concept, perhaps justifiable up to a certain point, there has developed an alarming smugness among the ill-informed. Not only do these people irritate their betters in the public health field, but, potentially at least, they are in position to do much harm. We concur in the thesis that public health workers must be disciplined to analyze and to synthesize mentally, and we agree that one should not accept encyclopedic knowledge as a test of mental capacity. On the other hand, in modern public health work one must be armed with more than an ability to think straight, even though this ability is a commendable and rare one. In addition, it is necessary that physicians, nurses, engineers, dentists, health educators, and others carrying on health services possess both fundamental knowledge in the sciences basic to public health and detailed information in the special categories in which they work.

These things seem worth mentioning for two reasons. First, because young workers in public health, sometimes discovering an astonishing and distressing lack of technical knowledge in their superiors, may be misled into a belief that ignorance is no barrier to promotion and prestige. It must be admitted that persons rather ignorant professionally do sometimes get along fairly well in the public health field. This, however, is quite the rare exception. When it occurs, the individual concerned possesses some element of personality, force, or smoothness that masks deficiencies in knowledge; or perhaps by his own shrewdness or with the help of his patrons he has been able to grasp time by the forelock. Similar accidents

occur in other fields, too, but the average uninformed person has no grounds and no right to hope that it will happen in his case. The second reason for discussing the necessity and worth-whileness of obtaining and retaining basic scientific information is that young workers in the public health field are inclined erroneously to assume that one may grow in knowledge only by attending formal courses of instruction. This is not true. If one really wants to add to his store of information, there are no places or circumstances in continental United States where, through one means or another, the necessary texts, facilities, and equipment cannot be obtained, providing the urge to knowledge is strong enough. Nor is the opportunity and necessity for learning limited to the younger workers in the public health field. Health officers, executive secretaries, directors, and, if they are diligent, professors, may hope to acquire basic and detailed knowledge of public health.

A side light on what may happen when the uninformed get to chucking their weight about is illustrated by the case of an examiner, in a profession supplementary to medicine, who was long on method but short on fact. Scorning the old-fashioned questions that required narrative answers, she examined by the multiple choice technic and asked candidates to decide whether it is in malaria, typhoid fever, or pneumonia that *Peyer's patches* are found.

Credit Lines

THE COMPLEAT (ANNUAL) REPORTER

AT the request of the Editors of Credit Lines, an Izaak Walton went angling in a sea of health department annual reports a little while ago. Our Izaak is RAYMOND S. PATTERSON, PH.D., Director of Health Education, John Hancock Mutual Life Insurance Company, Boston. Now he displays the contents of his creel. The next voice you will hear will be that of Dr. Patterson.

What's an annual report? Seems a pointless question to ask, doesn't it? But there is plenty of evidence spread out upon my desk to suggest that the question has never occurred to a good many health officers. If, as you will tell me, an annual report is a year's end accounting of the activities of a health department made to the residents of the community, who have every right to know what their health department does for them, then one would suppose the annual report would be, in effect, a message something like this:

Dear Squire (or Dear Mrs. Nabob): Your health department performed these several services to protect and promote your health during the year. We wish that we might have done thus-and-so for you, but we were prevented for these reasons. If you want figures to support our statements, here is a mercifully condensed DIGEST of the complete compilations which are on file in our office and always open for your inspection, so we won't bore you with the details here. If you would like to know the names of your hired help in the health department, here at the close is the staff. We thank you.

Such a yearly "news letter" written

in a pleasing and sprightly style, illustrated with *new* pictures, not too posey, would be read with interest by many of the influential people in town to whom it should be sent, and it would be snapped up by the editor of the local Tageblatt for a news story (perhaps with a nudge from you).

The reason I asked the question, "What is an annual report?" is that most of the tomes displaying that label, and which have come to this desk from a score of American communities, bear so little resemblance to what one would assume a report would be like.

Here is a sort of composite photograph of the majority of city health department reports, with my ill-natured comments in italics.

Title page announces the breathless news, "Annual Report of the Department of Public Health of the City of New ——— 1942." *Why not give your report a title which "says something" about the nature of the year's work. The words "annual report" long ago earned a reputation for deadly dullness.*

Page 1: Long lists of city officials, board members and complete staff of the health department down to the bottle washers in the lab.

These names are chiefly of interest to the owners thereof. If the record is needed why not put it at the back, as a sort of signature to the report? Readers will appreciate your help in getting quickly to the point, if any, of your story.

Page 2: Stilted letter of transmittal to his Honor, the Mayor, and the Honorables, the Members of the Common Council.

Ho! Hum! The reader sighs, maybe we'll get through this verbal trash pretty soon!

Pages 3 to 7 or 8: Mortality statistics, morbidity statistics, plain statistics—about nursing visits, sanitary inspections, and numbers of deceased felines removed from gutters.

By what reasoning do you suppose all the able health officers, who are responsible for these reports, come to the conclusion that readers will wade through these long tabulations? And if they did, would they remember anything useful about local public health administration when the reading was done? (Both questions are rhetorical.)

Pages 9 to 12: Uninspired narrative reviewing in most prosaic words possible to find, every single activity of the health department throughout the year; with newsworthy items smothered between "the same old stuff."

Dear Doctor Health Officer: Your report is a letter (in effect) telling the Squire a few things he should REMEMBER about your activities of the year! So dress it up. Use "picture" words, and real pictures too if you can get good ones! Accent the high lights with flashes of descriptive writing! Don't put your reader to sleep!

We've said enough! Too much, in fact.

From among several excellent reports I select this annual accounting from the Southland as a good example of the way it might be done.

The cover of this 16 page, photolithographed and economically printed brochure is eye-catching, with a striking silhouette of a statue of a soldier on guard. The title is "Keeping Watch," the place is Forsyth County (Winston-Salem, North Carolina), the year is 1942.

The foreword "Keeping Watch—Over Health" reminds the reader that the job is a responsibility in which he

has a definite part, to look after his own and his family's health and to take an intelligent interest in the public's health. A striking contrast of photographs of business tower and share cropper's cabin drives home (on p. 3) the point that public health is the health of *all* the people. On the pages that follow is told the story—in unposed, convincing pictures, with captions that "say something" about them, not mere labels—of the health department's services for expectant mothers, infants, toddlers, and school children, and how it helps to guard against communicable diseases, including tuberculosis and syphilis, and what it does to improve community sanitation. At the end of the story is listed the staff.

A postscript entitled "Good . . . But Not Good Enough" reproduces the citation of the Inter-Chamber Rural Health Conservation Contest and under the picture of a bright-eyed urchin, are listed all the laudable and reasonable objectives to which the department is "Looking Forward."

That, good friends, is one swell report. To its producers I doff my cap, mightily impressed with the interpretative brains, the sparkling ingenuity, and the plain hard work that went to make it what it is.

There are other good reports that might have been mentioned: the always excellent New York City year book, for instance. But had that one been chosen, many readers would have shrugged it off with a "Why shouldn't New York have a good one? Now in my case . . ." Birmingham, Alabama, again "rings the bell" with a report entitled "Public Health and a National Emergency." But Winston-Salem's deserves to stand out sharp and clear, not to be overshadowed by the competition of publications from bigger and wealthier places.

RAYMOND S. PATTERSON

ADVICE ON LANTERN SLIDES

Dr. James E. Perkins, Director of the Bureau of Communicable Diseases, New York State Health Department, is Secretary of the Association's Epidemiology Section. He has just sent a mimeographed letter to all the speakers on his Section program at the War-time Conference in New York City, October 12-14, giving some excellent advice on the preparation of stereopticon slides. Because slides are so generally used to illustrate scientific papers, we share his communication with *Journal* readers. Unfortunately we cannot reproduce the effective examples referred to in the second paragraph, but Dr. Perkins would be glad to send copies, we feel sure, to any inquirers. The text provides a good idea of what they are. This is the letter:

TO ALL SPEAKERS ON THE PROGRAM
FOR THE EPIDEMIOLOGY SECTION,
AMERICAN PUBLIC HEALTH ASSO-
CIATION:

An excellent paper can be ruined by lantern slides which are not legible or fail to present the message which the speaker wishes to convey. No doubt you, yourself, have at times groaned when a slide has been thrown on the screen which was legible only to those sitting in the first two rows (if to them). Hence, this routine communication to all speakers on the Epidemiology Section Program, suggesting care in the preparation of slides.

The slide should be a condensation of the important points, and not a work sheet. Example 1 shows the type of table that is really a work sheet and has too much data to enable the audience to grasp the material contained therein. Because of the numerous categories, the figures on such a table will be visible only to the first row or so. Tables as complicated as this have not infrequently been presented before the Section. Such a table should be broken down into several simple tables. Example 2 shows a condensation of part of the data given in Example 1, and represents a slide actually presented before one of the meetings of the Epidemiology Section. Some of the other data in Example 1 were presented in separate equally simple slides.

Remember that the tables used in the slides do not have to be the same tables in the paper presented for publication. Published tables can be more elaborate and contain more data, since the reader can study them at his leisure, but tables used for lantern slides should give only the essential data necessary to make the point desired.

Material on the slide should be not more than fifteen lines deep (and preferably about half that) and contain not more than half a dozen categories horizontally. If such data are well distributed over the slide, the projected image will be legible at the rear of the average size meeting room with the usual projector and usual screen.

Summarizing, then, please attempt to have your tables for lantern slides (1) present only the condensed summary of the important points, (2) comprise not more than fifteen lines, including the title, and not more than six columns across, (3) be so composed and so prepared by the slide maker that this material covers the slide, so that proper magnification will occur upon projection.

We will do our part by seeing to it that there are provided a good screen and projector, in good working order.

LEST WE FORGET

Those of the younger generation who are inclined to forget what the sanitary base line was against which our recent progress may be recorded will find pleasure in reading Professor Yandell Henderson's essay "Recollections of a Street Corner Pump and the Progress of Sixty Years" in *Science*, Vol. 98, No. 2532, pages 25-28, July 9, 1943. It is an interesting account built around Professor Henderson's experience in Louisville, Ky., where he was associated with distinguished members of the Flexner family, Simon and Abraham.

DO YOU AGREE?

President Roosevelt's recent message to Congress requesting \$400,000,000 for housing for war workers, thus bringing the total authorization for this purpose under the Lanham Act to \$1,600,000,000, brings to mind a comment of Professor C.-E. A. Winslow, speaking before the Eleventh Annual Meeting of the National Association of

Housing Officials in New York City. Professor Winslow was roundly applauded when he said:

"We are all familiar with the signs customarily placed at the entrances of new housing projects for war workers pridefully crediting the projects to the local and federal agencies responsible for them. We should feel less apprehensive about the future if they were changed to read: 'This is War Housing, necessary but regrettable. To be demolished immediately upon the cessation of hostilities!'"

Subsequently, Commissioner Emerich of the Federal Public Housing Authority, officially endorsed Professor Winslow's principle in his recommendations for post-war demolition of war housing. One plank in his program was that "Temporary housing built to substandard plans in order to save time and critical materials should be removed." In fact, there was rather wide agreement during the meetings of the National Association of Housing Officials that the glorified shoe-box dwellings built during the war (1,100,000 so far) must be got rid of promptly if the progressive housing movement is not to receive a serious black eye, and if public health and social workers are not to be confronted with new slum areas to harbor additional disease and misery.

A PATTERN FOR HANDLING REJECTEES

The Public Health Federation of Cincinnati, of which Bleecker Marquette is Executive Secretary, has published a 6 months' report on a consultation service for men rejected at the Cincinnati induction station whose cases were reviewed under the auspices of the Public Health Federation, in cooperation with the Cincinnati Board of Health. Those who are seeking to find a pattern of good relationships between a voluntary agency, the board of health, and the armed forces, would do well

to review the way these consultations have worked out in Cincinnati. Although primarily emphasizing the rejections on account of tuberculosis, the report also includes the cases rejected because of heart disorder, hernia, mental defects, syphilis, and other causes.

QUOTABLE ITEMS

"The vast majority of persons will not see a known case of tuberculosis unless they visit a hospital. What they know about tuberculosis, therefore, will be what we tell them, what health education gets over to them, and what new traditions are established in regard to a disease with which most people have no personal contact. This situation calls for more and better, and more continuous, health education as to tuberculosis."—Homer Folks, July, *N.T.A. Bulletin*.

From a bulletin board in a Wisconsin mill where a tuberculosis survey was being made, "If every person in our mill but one has his lungs examined, that one is protected 100 per cent, but all the others are not protected from him."

"The efficiency of a board of health and the respect which will be shown it in a community will depend very much upon the firmness with which the members insist upon a strict compliance with all needful sanitary regulations as well as the caution they display in avoiding needless exactions and unnecessary investigations."—Honorable Leroy Parker in the *Annual Report of the Michigan State Board of Health for the year 1879* and published in *Health News*, New York State Department of Health, July 19, 1943, under the caption "Still True."

MORE ON EPIDEMIC VOMITING DISEASE

Apropos of an editorial entitled *Is There an Epidemic Vomiting Disease of Winter?* which appeared in our April issue, readers of the *Journal* may be

interested to know that an article on this subject was published in the March 13, 1943, number of the *British Medical Journal*. An abstract of the article appeared in the *Journal of the American Medical Association*, June 12, 1943. For this information we are indebted to Dr. John J. Sippy of California, who has himself studied epidemic vomiting outbreaks.

AWARDS FOR MILK PRODUCERS

J. L. Rowland, the Chief Sanitarian of the Oak Park, Ill., Department of Health, has announced a quality milk program offering to each milk producer a certificate of award "in recognition of noteworthy achievement in sanitation and quality milk production."

The requirements include a methylene blue test of 6 hours or more and bacterial counts not to exceed 200,000. The number of defects on the inspection sheet is limited. A persuasive letter explains the proposal to the milk producers and is signed by Gilbert P. Pond, M.D., Commissioner of Health.

THE OWI

The Office of War Information has been the recipient of many brickbats and of few bouquets. We timidly approach with our nosegay. Of course anyone on their mailing list received a great deal of material before an unappreciative Congress curtailed their domestic activities. The reason is simple. This is a big war, affecting every one of us in every aspect of our living, and there was much to say about it. Naturally a large amount of what was said had nothing to do with the particular problem on your mind when the daily releases or special publications popped up in the morning's mail. But a good deal that was seemingly extraneous at the moment was genuinely informative to people aware of their century. These additions to general knowledge and background in-

formation were painlessly made. Further, and more practically, they could be drawn from or quoted (no copyright) to put the stamp of timeliness on a piece of printed matter or a speech to disguise the fact that the same old record was about to be played.

The "true story" about absenteeism, told by OWI, and one on British in-plant canteen services, to select two for mention from a great many quite as worthy, were for us as citizens first and as public health workers second—and good reading all the way.

News from the Department of Agriculture, from the Bureau of Mines, and from the Federal Security Agency, released in one day through OWI, all contained pertinent information for health workers and were published in the *Journal*.

The thorn in our nosegay to OWI is turned so that it pricks us. They made their stuff so interesting that many times the problem on our minds when the morning mail was tackled was still there at noon. That article on kok-saghyz, the Russian rubber-producing dandelion, for instance, contained not an implication that the plant has any food value to assuage our sense of guilt at having read every word. We are going to miss things like that and similar pieces of "fourth term propaganda."

MANUAL FOR VOLUNTEERS IN MASS CHEST X-RAY EXAMINATIONS

As an outgrowth of experience in chest x-ray examination projects on a large scale which were organized and conducted jointly by the Hartford Board of Health and the Hartford Tuberculosis and Public Health Society, a *Manual* has been prepared for guidance of volunteer crews that may be called upon to participate from time to time in such projects under health agencies.

The outline covers the services of the

supervisor, the dressing room attendant, the registrar and dark-room operator. Copies of the *Manual* may be obtained on request from the Hartford Tuberculosis and Public Health Society, Hartford, Conn.

WORTH ACQUIRING

Manual of Industrial Nutrition, first in a series to be prepared and distributed by the Nutrition in Industry Division, Nutrition and Food Conservation Branch, Food Distribution Administration, Washington, D. C. Contains brief chapters on the National Nutrition Program for Industry, on the nutritional status of industrial workers, basic and special considerations for an "in-plant" program and source lists of posters, pamphlets, films, news services, and radio scripts.

Leaflet on *Meningococcus Meningitis*, from Health Department, Baltimore, Md., Huntington Williams, M.D., Commissioner.

The Woman's Home Companion for June for its article "Change Your Food but Keep Your Figure"—reassurance that food rationing need not affect weight.

The Architectural Forum for May for its plans and drawings of the post-war hospital and health center.

The Bulletin of the Health Organization of the League of Nations, Vol. X, No. 1, devoted to Typhus Fever.

"What's More We Like It!" subtitled "Greenwich Answers to the Leaner Larder." Not every community has a Hendrik Willem Van Loon resident therein and not every Tuberculosis Association could induce him to illustrate a book of wartime recipes. The Greenwich, Conn., Tuberculosis Association has done just that and turns out a generous cookbook with all the right advice temptingly presented.

The February (Twentieth Anniver-

sary) issue of *Channels* published by the National Publicity Council for Health and Welfare Services, Inc., 130 East 22nd Street, New York, N. Y., for its Publicity Directory which selects the most useful publications on how to use media and a list of major sources of publicity material (40¢).

Rheumatic Fever in Children—Its Recognition and Management, a 32 page clinical handbook written for the practising physician. A limited number of copies are available from George M. Wheatley, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y.

The War and Social Problems—A Selected Bibliography, material to April 1, 1943, compiled by Karl A. Baer for the Russell Sage Foundation, 130 East 22nd Street, New York, N. Y. (20¢). References are classified under such headings as women, children, and young people, general health problems, nutrition, social hygiene, mental hygiene and morale, post-war planning, etc.

Radio Script No. 156, "The Story of One of Us," by Hubert Chain, published by the Radio Script Service and Girl Scout News Bureau, 155 East 44th St., New York, N. Y., for its dramatic handling of the experiences of American Red Cross nurses in Bristol, England, during the paratyphoid epidemic. It brings in the Medical Officer of Health of Bristol, Dr. Robert Hughes Parry, Elizabeth Phillips of the Henry Street Nursing Service who has been on the staff of the American Red Cross in England, and others.

The new publication of the National Tuberculosis Association on *Personnel Problems of Sanatoria Resulting from War Conditions*, for its systematic canvass of facts on personnel in a cross-section of American sanatoria. It is succinct and to the point and the mem-

bers of the Committee on Sanatorium Standards of the American Trudeau Society, of which Victor F. Cullen, M.D., is Chairman, are to be congratulated for producing this practical document.

An article entitled "Nutrition Exhibit, East Orange (New Jersey) Health Department, 1942," by Frank J. Osborne, Health Officer, for its careful inclusion of the sources of all display material and printed matter used in an ambitious five section exhibit. Reprints free on request to Mr. Osborne.

This week, and every week, "Health Articles of the Week, an Index to Current Periodical Literature on Public Health," compiled by the National Health Library, 1790 Broadway, New York, N. Y. Now in its 23rd year of publication, this weekly reference list averaging 4 mimeographed pages, directs attention to the important articles in all health and medical magazines under such headings as general, cancer, child welfare, communicable diseases, eyesight conservation, health education, health insurance, heart disease, industrial hygiene, mental hygiene, national defense and war, nursing, nutrition, tuberculosis, venereal diseases. Sample copy on request; subscription \$2.50 per year.

PUBLIC HEALTH IN MICHIGAN MARKS ITS 70TH BIRTHDAY

The July issue of *Michigan Public Health*, published by the State Department of Health, is given over to a historical review of 70 years, since July 30, 1873, when the Michigan State Board of Health was created. The story includes many of the persons who have left the impress of their lives on Michigan during these years. Its effect is to build up public appreciation for public service rendered through health agencies.

"THE BEGINNINGS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION"

Under the title "The National Quarantine and Sanitary Conventions of 1857 to 1860 and the Beginnings of the American Public Health Association," Harold M. Cavins, the Assistant Professor of Hygiene in the Eastern Illinois State Teachers College, Charleston, Ill., has published a paper in the *Bulletin of the Institute of the History of Medicine*, Vol. XIII, No. 4, April, 1943.

In view of the fact that the original sources of much of this information are difficult of access generally, the public health profession is in debt to Professor Cavins for putting this review on record. It is a very readable story.

BOOKS AND REPORTS

The Food You Eat—A Practical Guide to Home Nutrition—By Samuel and Violette Glasstone. Norman: University of Oklahoma Press, 1943. 277 pp. Price, \$2.25.

The first few chapters of this book stress the physiology of nutrition, its relation to health, and the processes of digestion and energy metabolism. Next in order, mineral elements and water, then vitamins are discussed. A chapter on food products discusses the various groups of foods—cereal foods, dairy products, etc.—and the last chapter is devoted to "Planning the Menu." A section at the end of the book "Practical Nutrition in Outline," gives a brief summary of daily menu planning and of the requirements, functions, and sources of the various food components.

The title of this book leads one to think it is written for the homemaker, or at least for the lay reader. The use of words like creatinine, protein linkings, amino acids, and sterols do not add to the value of the book for lay persons. The use of these technical terms marks the book as a reference text for high school or young college students. As a matter of fact, the book is too technical and too wordy for easy popular reading. It is not a new approach to the subject of nutrition but a repetition in heavy detail. One is led to conclude, therefore, that the authors, one a physical chemist, the other a plant physiologist, were not conversant with nutrition in its relation to the problems of homemakers to discriminate as to what might be omitted and still have the story of nutrition effectively told.

For the most part the information is accurate. However, there are statements which might be questioned. The

chapter devoted to menu planning often reverts to the authors' whims instead of being based on scientific facts. Because they eat little or no breakfast does not make the practice a sound one, neither is there a scientific reason for the omission of bread in certain meals, nor is there any reason why lunches should always contain sandwiches, nor that milk should be omitted from a meal when lemon meringue pie is eaten.

It is to be regretted that the authors chose to use the terms P.P. factor instead of niacin, vitamin B₁ and vitamin B₂ instead of thiamin and riboflavin, respectively.

MARIETTA EICHELBERGER

Miracles of Military Medicine—By Albert Q. Maisel. New York: Duell, Sloan and Pearce, 1943. 373 pp. Price, \$2.75.

This book discusses very important matters and contains some reliable information, but it is a typical example of the danger of a layman writing on technical subjects. A few instances will suffice.

The author says that diphtheria antitoxin is more properly called "toxin-antitoxin" since it contains "not only the good antigens but also the bad diphtheria toxins." In regard to tetanus, he says that "until the first World War all cases were untreated." In 1897 Nocard sent tetanus antitoxin to 63 veterinarians, advising its use after operation. Among 2,727 animals so treated not one developed tetanus, while 259 untreated animals developed tetanus. Between 1898 and 1906 in France, 13,124 animals operated upon or wounded accidentally received antitoxin as a prophylactic, with not one case of tetanus (Vaillard). By 1905

the nonmedical officers of the French Army had been instructed to have all cases of wounds in army horses treated with tetanus antitoxin, yet according to the author, one would think that Ramon's work in 1926 in the French Army with his anatoxin was the first attempt to prevent tetanus in the cavalry, and he says "the rest of the world was just beginning to wake up to the import of his tetanus discovery." We give all credit to Ramon for his work, but alum precipitated toxoid, now almost entirely used, was described by Glenny *et al.* in 1926. It is true that the commercial manufacture making it generally available did not start until considerably later in this country.

In 1903 the *J.A.M.A.* began its campaign for the treatment of Fourth of July toy pistol and fireworks wounds. In 1914, among 1,506 such wounds, there were only 3 cases of tetanus and in 1916 there was not a single case.

These examples seem sufficient to put this book where it belongs. It will probably interest some readers and may do some good. The author is "conscious of the pitfalls that beset the lay writer who ventures a popular discussion of medical subjects," and gives an imposing list of men, mostly well known, who gave him information for his book. It seems to go without saying that the text was not submitted to anyone who knew anything about bacteriology. The book cannot be recommended as it will spread misinformation as to dates, credits, and facts.

MAZÏCK P. RAVENEL

Blood Groups and Transfusion—
By Alexander S. Wiener, M.D. (3rd ed.) Springfield, Ill.: Thomas, 1943. 438 pp. Price, \$7.50.

In Wiener's *Blood Groups and Transfusion*, a well bound and well printed volume, the author has added two new chapters in this third edition which is printed 38 months after the second in

1939. This volume summarizes as the author proposes: the present knowledge concerning the theory and technic of blood grouping; its application in clinical, legal and veterinary medicine and in anthropology, and assembles and integrates the essential facts concerning the transfusion of whole blood, plasma, and serum.

The volume is well illustrated with 69 figures, and many essential data are assembled in 106 tables. The handling of the accumulated literature is accomplished by references placed at the bottom of the page and by a General Bibliography at the back of the book. In this section also there is an appendix treating by statistical means the calculation of the genes A, B, and O if the distribution of the blood groups is known. The subject index is covered in 11 pages. There is no author's index.

In the new chapter on transfusion of stored blood, plasma, and serum, reference is made to Robertson's transfusions of stored blood in World War I. Due credit is given to work of Filatov and Bagdassarov in Russia and to the establishment of the first blood bank in this country at the Cook County Hospital by Fantus.

The question of survival of the transfused stored erythrocytes is well answered by the author's experiments using anti-M and anti-N agglutinating sera. These tests conclusively show that while fresh blood or blood only a few days old survives for periods up to 3 or 4 months, older blood disappears from the patient's circulation much sooner: i.e., blood stored for 21 days was found to survive only 24 hours. The author rightfully emphasizes the necessity of the collection of stored blood under a closed system, because the greatest problem in relation to plasma and serum transfusion is the prevention of contamination by bacteria and fungi. The safety of pooled plasma

is enhanced by pooling ten or more samples because the titer of the isoagglutinins is diminished by the factor of dilution and also to some extent through the neutralization of the isoagglutinins by group substance in solution. Various methods of drying plasma are presented with the correct admonition that plasma dried from the frozen state is to be preferred.

The second new chapter "Factors Rh and Anti-Rh of Human Blood" marks a lasting advancement not only because of the clinical importance of the Rh factor in reactions associated with repeated transfusions but also in the field of obstetrics in which the Rh factor is concerned with erythroblastosis foetalis, neonatal deaths, miscarriages, and congenital anemia of the new-born. Landsteiner and Wiener have shown that the Rh agglutinin is a dominant gene. The chapter is purposely headed "Factors Rh." With the aid of standard anti-Rh sera, individuals are divided into only two types: Rh-positive and Rh-negative, the ratio being 85/15 among the white population. Wiener, however, shortly after the discovery of the first Rh agglutinin, obtained from the serum of a patient who had a hemolytic reaction, an irregular agglutinin which acted on 70 per cent of bloods. A third type of human anti-Rh serum gives about 87 per cent positive reactions with the bloods of white individuals (Levine).

This knowledge will not only explain much of the pregnancy wastage due to mis-mating but will lessen intra-group hemolytic reactions, particularly those seen in certain pregnancy cases.

This book should become the standard text in medical schools and should be in the possession of all blood banks.

JOHN SCUDDER

Guide to the Inter-American Cultural Programs of Non-Government Agencies in the United States. Com-

piled for the use of the Office of the Coordinator of Inter-American Affairs. February, 1943. 181 pp.

The *Guide to the Inter-American Cultural Programs of Non-Government Agencies in the United States* is a worthy attempt at a comprehensive listing of nonofficial organizations in this country with Inter-American interests.

The format is somewhat sketchy, but the context should be valuable from a reference standpoint even though some omissions must be expected in an initial work of this nature. The descriptions of these agencies and institutions is entirely uncritical, but the outline of their activities and the names and addresses of their principal officers should be very useful to those individuals and officials who have to do business with the other republics.

EDWARD C. ERNST

Cases of Syphilis under Treatment in Cuyahoga County during March 1942—By Howard W. Green. Foreword by Dr. James A. Doull. 62 pp. Paper.

This report is the fifth in a series of consecutive annual statistical studies of patients treated for syphilis during the month of March, 1942, in Cleveland, Ohio. Since the schedules from which the information was compiled are identical with those used in 1938, 1939, 1940, and 1941, it is obvious that changes in the extent of syphilis under treatment, whether infectious or non-infectious, new or old, and treating agency can be easily ascertained. The study is presented mainly in the form of tables, charts, and graphs, with a minimum of text. An excellent summary recapitulates the findings of individual phases of the entire project, which provides factual data on the treatment status of syphilis in a large urban community. The observations recorded and problems encountered parallel those in similar areas.

The coöperation of the physicians of the community in answering the questionnaire (99.7 per cent replied) indicates a very helpful attitude on the part of the medical profession. Physicians treated more cases in 1942 than in the previous year; one wonders what effect the reduction of physicians in the civilian community, caused by the needs of the armed forces, will have on this finding next year, and whether the community facilities for the care of a larger load are adequate, particularly in view of the comment on page 57 "facilities for the treatment of syphilis in several of the hospital out-patient-departments are still being severely over-taxed by the enormous number of cases under treatment."

It is noted that the vast majority (83 per cent) of all cases of syphilis under treatment were non-infectious. It would be interesting to learn what percentage of these cases had already received the maximum benefit of therapy and for this reason should have been placed on "observation status" and no longer treated. In this connection the significance of Dr. Vonderlehr's recent statement becomes increasingly important "evidence shows that late and late latent syphilis now receives more attention in public clinics than is justifiable from a public health standpoint. It is essential that everything possible be done to provide adequate medical treatment for early patients and to discourage the attendance of the others, beyond the time when adequate treatment has been given. This idea should also guide the case holding." The problem of the patient with infectious or potentially infectious syphilis who lapses treatment before being rendered permanently non-communicable is emphasized.

The author and the Joint Social Hygiene Committee of the Cleveland Academy of Medicine and the Cleveland Health Council, which sponsored

this study, are to be commended on an important contribution to the literature of syphilis control in this country.

THEODORE ROSENTHAL

Discovering Ourselves—A View of the Human Mind and How it Works—By Edward A. Strecker, M.D., and Kenneth E. Appel, M.D. In collaboration with John W. Appel, M.D. (2nd ed.) New York: Macmillan, 1943. 434 pp. Price, \$3.00.

There can be little or no question concerning the need for more general dissemination of the methods of maintaining emotional health. Nor can there be question about the difficulty of communicating these methods to the public. In the second edition of the authors' popular presentation attempts are made to reduce the tabu of emotional and mental phenomena by recourse to simple definition and description of human emotions. These attempts are illustrated by clinical anecdotes and graphs. The additional chapters which concern emotion, anger and fear are of timely significance in the present world crisis with the need for adaptation to unrest and change.

In an appendix a series of questions are asked in an attempt to test one's understanding of the topics discussed. While it is quite possible, as the authors state, that one will experience a practical exercise in psychiatric therapy and promote one's own mental health, asking and answering questions may be far afield from the goal of effective emotional insight. One always has to consider the plight of the starving man who found a menu card of little value in appeasing his hunger.

The therapy that is favored throughout the book is that of greater self-knowledge concerning both the nature of mental conflict and the various means of dealing with it. The authors express confidence that such self-knowledge will do much toward attaining more

constructive methods of emotional adjustment.

JOHN ROMANO

Building Morale—By J. B. Nash. *New York: Barnes, 1942.* 154 pp. Price, \$1.00.

This book is unfortunately representative of a considerable number of publications and utterances upon morale. Written in an ecstatic, rambling style, it proceeds in a series of exhortations and emotional crescendo to its end without at any time bringing forward either valuable theory or practical planning concerning morale.

This phenomena of human behavior, morale, has attracted the liveliest attention from men of the most varied experience and attainment. Fascinated apparently with what has been accomplished by the Nazis through psychological warfare, representatives of the clergy, the army, journalism, women's clubs, and those interested in the cultivation of victory gardens have all hastened to express themselves. The results, as here, have been almost uniformly unfortunate. Morale is a part of human behavior and can only be dealt with informatively by those who have a background of training in the sciences which are concerned with that field.

D. EWEN CAMERON

Social Hygiene Year Book—1942. The Program in Action in the States and Communities. *New York: American Social Hygiene Association, 1943.* 252 pp. Paper. Price, \$1.00.

This paper bound volume collects, under one cover, a series of summaries of "current events and progress on the forty-eight fronts" which appeared in the *Journal of Social Hygiene* for April, May, and June, 1942. It aims to report the work of official and voluntary agencies since the last report, in 1938, and it is described, further, as "No. 1 in a new Journal series on Social Hygiene in Wartime."

State by state, in alphabetical order, it reviews the expansion of the programs of state and large city health departments and social hygiene societies, primarily as they are related to the war. It ranks each state according to population, indicates the number of A. S. H. A. members in each, provides a directory of state and national official and voluntary agencies concerned with social hygiene, and the names of their current executive officers.

The program material provides a fair indication of the current direction of the social hygiene program. Being a "progress report" it does not attempt to present the over-all social hygiene program of each state, although in some instances, this is woven into the progress report. Thus, the material is rather "spotty" in that it permits a view of some of the high points of the superstructure, but relatively little of the main edifice or its foundation.

There are four appendices, which outline the A. S. H. A. program, reproduce "important letters and documents," present and discuss certain "social hygiene laws and regulations," and display a collection of charts, tables and propaganda.

N. A. NELSON

Public Health and Preventive Medicine—By Morton C. Kahn, M.A., Ph.D., D.Sc. *Oxford Medical Outline Series. New York: Oxford University Press, 1942.* 2 Vol. 534 pp. Price, \$4.00.

An attempt to condense the entire field of public health into two pocket size 250 page books is a difficult feat. The author's solution has been to devote 390 pages to the Transmissible Diseases, but only 77 pages to Environmental Hygiene, and 48 pages to Public Health Administration. Obviously, the Transmissible Diseases overwhelm the rest of the Outlines. As an example, the 5 pages devoted to Anthrax and the 7 to Botulism outnumber the entire

presentation of Industrial Diseases. The latter discussion consists merely of 4 pages assigned to Silicosis, Asbestosis, and Lead Poisoning, and of 7 pages wherein are listed inorganic and organic chemical poisons with their industrial exposures. In the section devoted to the Environment, there is no presentation of illumination, no mention of food and restaurant inspection under Food Sanitation. Three full pages are devoted to Certified Milk, and 1 to the New York City milk supply, without mention of the phosphatase test. Under *Water*, no allusion is made to softening nor to taste and odor control. Orthotolidine is mentioned under *Sewage* but not in *Water*. The discussion of nutrition is confined to listing the vitamins and outlining their sources, requirements, stability, effects of deficiency and therapeutic doses, and to listing the essential amino acids.

Public health workers and students desiring an outline of communicable diseases will find these Outlines useful. These various diseases are presented under the headings of Etiology, Symptomatology, Epidemiology, Transmission and Prevention, with appropriate subheads. There are few inaccuracies in these sections. However, some appear. On page 404 yellow fever vaccine is rightly claimed to be produced from chick embryo, while on page 346 it is said to be grown on the chorio-allantoic membrane. One would hardly concur with the suggestion (page 464) of waiting for a Widal test to eliminate typhoid fever in the differential diagnosis of trichinosis. In the section on typhoid fever the importance of blood cultures in early diagnosis is properly stressed, although the technic (page 222) is poorly described: "During the first 10 days take several specimens of blood and plant in nutrient agar." Furthermore, one does not obtain fecal specimens from the duodenum.

The section of Environmental Sani-

tation has gross inaccuracies. Mussel poisoning (page 14) "may be a sex toxin due to spawning" (no mention of *Gonyaulax*). "All ground which cows traverse should by proper drainage be kept free from mud, puddles and manure" (page 29) is a statement which could have been eliminated with benefit. In Refuse Disposal the method used with success from New York to San Francisco, Fill and Cover, is not defined specifically. Its closest approximation is "mixing organic refuse with ashes." The description of an Imhoff tank is as follows (page 49): "A large cylinder has an upper chamber connected to a lower chamber by a funnel with a slit in the bottom . . . Gases thoroughly mix the old and new sewage in the upper chamber." The description of the activated sludge process would make it a discontinuous instead of continuous process.

Public Health Administration is also weak. Allocation of space is without much discrimination. Ten pages are given to the United States Public Health Service with only 3 pages to State, 5 to County, and 6 to City Health Departments. Actually, state and local venereal disease control is outlined under the United States Public Health Service. The Outline is inaccurate in listing as separate categories in Personnel of the State Department of Health both a Commissioner of Health and a State Health Officer.

Unqualified, sweeping statements consequent to outline form are particularly objectionable in this section on Administration. It is declared unwise to have a commissioner appointed by a governor, although, properly safeguarded, many would disagree with this opinion, and no alternatives are mentioned. On the other hand, the State Health Officer "selects and discharges subordinates" (page 482) (without regard to Merit System?). "School children should be tuberculin tested and

x-rayed" (page 470) (including grammar school children?). "Medical examination and treatment must be provided for workers" (page 472) probably alludes to industry, but is so presented that apparently it refers to the Municipal Health Department. On page 477, laboratories are dogmatically forbidden to County Health Departments while "at least $\frac{1}{4}$ of the budget" of County Health Departments "should be permanently subsidized by the State" (even in large, wealthy counties?).

The Outlines are well printed and have an excellent index. Blank pages are interspaced every 5 to 8 pages for notes. However, aside from the sections on Transmissible Diseases, the books will have a very restricted usefulness.

CHARLES E. SMITH

Transactions of the Ninth Institute on Public Health Education—*New York: American Public Health Association, 1943. 56 pp. Price, \$1.00.*

This volume is a valuable contribution to material on health education. We were asked the other day where and how one would find the best examples of health education in this country that might be visited and studied, or that might be reviewed by correspondence. We expressed the opinion that when this volume appeared it would constitute such a source of information and guidance, and we believe that it does.

In this report of the proceedings of the Health Education Section in St. Louis, one will find the products of up-to-date conference methods—informal group discussions with well selected panel leaders, assembling and interpreting information regarding community activities as laboratory material, all based on a recognition that maximum results necessitate a community plan, though not a universal standard pattern.

The "large urban area" is ap-

proached from many angles, including the participation of the schools in teaching health behavior and the rôle of the public health nurse as an educational influence in the home. The "smaller urban area" discussion brings out interesting references to the "Bridgeport Plan"; to the development in a populous community of volunteer workers, assisting the public health nursing personnel; to the organization, in certain southern areas, of district or block neighborhood groups (going back, perhaps unconsciously, to the Cincinnati Social Unit Experiment of 1916). Explored, also, are the activities and needs of the "urban-rural area" and the "rural area."

Dr. Philip S. Platt, fresh from the National Health Council study of voluntary health agencies, interprets public health effort as a phase in public relations. School and health department relationships are summarized by authorities in that field, such as Dr. Mayhew Derryberry, and Dr. George M. Wheatley, while exhibit technics are expertly interpreted by Homer N. Calver and Dr. Bruno Gebhard—from the angles of both war and peacetime needs.

This report reflects that throughout this session there was a keen awareness of the current political implications of public health work in general and of health education in particular. In this country we are choosing afresh the methods of democracy which, in public health as elsewhere, must depend on education. The Institute feels that our problem in this country is to create among individuals and communities "an understanding of and a desire to take part in the solution of their own health problems." Professor C.-E. A. Winslow in his keynote address, "Health Education in a Democracy," said: "The problem today is 'Can we on our side achieve coöperative action by common consent? Can we

do it in the war? Can we do it in the peace that follows? ”

Finally, there is also indicated an awareness that if we are to have sound health education, we must have soundly trained health educators. Standards and qualifications must be recognized and met—a point stressed by Dr. William P. Shepard in his address at this session, on “Educational Qualifications for Health Educators”—a report of the Committee on Professional Education of which Dr. Shepard is Chairman, and which has subsequently become available through the *A.P.H.A. Journal* and otherwise. As Dr. Shepard points out: “A great advance will be made when educators and public health authorities can agree on the functions,

responsibilities, values, and training of those professional people who wish to devote themselves to the field of health education.”

Of course, we would expect such an Institute to be good under the direction of a committee and faculty that contains such additional names from the public health roster as Dr. Horning (director), Dr. Bauer, Dr. Coffey, Miss Connolly, Dr. Halverson, Dr. Hiscock, Miss Jean, Dr. Nyswander, Mrs. Routzahn, Dr. Turner, Dr. Wilson, Dr. Amyot, Dr. Clarke, Dr. Douglas, Dr. Gudakunst, and Mr. Marquette—to name only a few. The report also contains an excellent bibliography of 46 pertinent references.

Public Health on Land and Sea and Air—Some of the things the 1,800 full-time medical officers of the U.S. P.H.S. are doing at the ends, as well as the middle of, and above the earth are recounted by the one man who knows most about their various activities.

PARRAN, T. The United States Public Health Service and the War. *J.A.M.A.* 122, 16:1092 (Aug. 14), 1943.

It's about Scarlet Fever—Some quaint, isolated villages in Magda ("Red Head") Lupescu's Rumania—hamlets free from scarlet fever but in an area surrounding an endemic focus—were selected for a study of the population during preëpidemic, epidemic, and post-epidemic stages. The report upon this study covers seventy pages. Approaching senility, the need of a summer vacation, and a reprehensible incuriosity about the subject, all combine to unfit this annotator to do more than remind you that this wealth of epidemiologic enlightenment knocks at your door for attention.

SCHWENTKER, F. F., *et al.* The Epidemiology of Scarlet Fever. *Am. J. Hyg.* 38, 1:27 (July), 1943.

Healthy Soldiers—In no month has the venereal rate in this country even approached the lowest monthly rate of the last wartime period. In general it may be said that the health of the army here and overseas is satisfactory. Statistics are presented to convince Doubting Thomas.

SIMMONS, J. S. The Present State of the Army's Health. *J.A.M.A.* 122, 14:916 (July 31), 1943.

Who Talked First and Why—Here ye'are! Read all about it! The

ding-dong, the bow-wow, the pooh-pooh, the yum-yum, and the babble-babble theories of speech beginnings. It isn't public hygiene but it's entertaining.

THORNDIKE, E. L. *The Origin of Language*. Science. 98, 2531:1 (July 2), 1943.

Radiant Disinfection of Air—Exploring the hypothesis that the spread of communicable disease depends upon deficiencies of the atmosphere, the authors present evidence to show that a tenfold increase in winter ventilation (or its equivalent in ultraviolet irradiation) does prevent the spread of air-borne contagion.

WELLS, W. F., and WELLS, M. W. *Dynamics of Air-Borne Infection*. Am. J. Med. Sci. 206, 1:11 (July), 1943.

Professional People Are Also Citizens—As it tosses out a bold challenge to the sanitary engineers to

look beyond their technology and to take part in finding political, legal, and fiscal answers to post-war problems, this sparkling address should be read and taken to heart by all the specialists in the broad field of public health.

WOLMAN, A. *The Post-war Rôle of the Sanitary Engineer*. Sewage Works J. 15, 3:445 (May), 1943.

Influencing Human Eating Habits—Food store sales of the protective foods were used as a measure of the effect of an educational project in nutrition carried on in one section of a city. Marked gains in sales of a greater number of the protective foods were reported in the experimental area than in the control region. The advantages and limitations of this measuring device are discussed.

YOUNG, A. *A Method for the Evaluation of a Community Nutrition Program*. J. Am. Dietet. A. 19, 6:420 (June), 1943.

Wellington, 7th Avenue and 55th Street	2.50- 4.00	3.50- 6.00

MEETING OF THE COMMITTEE ON PROFESSIONAL EDUCATION

The Professional Education Committee of the Association held a meeting in New York City on June 11 under the Chairmanship of William P. Shepard, M.D., of San Francisco. Important action of this session included a resolution concerning the emergency shortage of public health personnel. The committee invited Dr. Joseph W. Mountin, Assistant Surgeon General of the U. S. Public Health Service, Washington, for counsel regarding the acute shortage of personnel in all branches. Dr. Mountin pointed out that in many states federal grants-in-aid remain unexpended because the local health departments are unable to fill positions. The Service had advocated filling at least some of these positions with auxiliary personnel, but response to this method had so far not been encouraging. He expressed the opinion that there was no justification for allowing the level of health work to fall on the theory that we must maintain preconceived notions with respect to the qualifications of personnel. The seriousness of the situation was illustrated by several members of the committee who cited instances where sanitary sewage was seen running in open ditches through heavily populated streets, areas where there is a great lack of maternity care, and frequent attacks of gastroenteritis among travelers because of the overburdened food handling facilities. It was further pointed out that supervision of water and sewage treatment plants and of milk pasteurizing facilities have been notably weakened by the withdrawal of those trained and experienced in this work.

In responding to Dr. Mountin's request for the committee's aid in the solution of this problem, the committee asked that this subject be considered in the program of the Annual

Meeting and the Committee on Professional Education formulated a memorandum for publication in the *Journal* and general circularization, indicating its awareness of this problem and advocating certain steps to be taken in its solution (see page 920 of the July, 1943, *American Journal of Public Health*).

The Committee on Professional Education received a report from its subcommittee on Merit Systems indicating that definite progress had been made and that the committee was now prepared to offer and was offering examinations for all classes of public health nurses and for most classes of medical health officers. The preparation of material for examinations of laboratory personnel was shortly to be undertaken.

The committee received and approved for publication a report on the Educational qualifications of Public Health Laboratory Workers (see page 882 in the July, 1943, *American Journal of Public Health*).

Similarly, a report on the Educational Qualifications of Health Educators was approved for publication (see page 998 in the August, 1943, *American Journal of Public Health*).

The committee considered further a report on Educational Qualifications of Medical Administrators which will include workers in maternal and child health, in tuberculosis control, in venereal disease control, in cancer control, and in mental and industrial hygiene.

A report was received from a new subcommittee under the Chairmanship of George J. Nelbach, New York, N. Y., on the Educational Qualifications of Executive Secretaries of Voluntary Health Agencies. The report, in the form of a first draft, was received and ordered circulated.

Further consideration was given to a report on the Educational Qualifications of Public Health Dentists, and

consideration was given to revision of the existing report on the Educational Qualifications of Health Officers.

A summary was presented of a preliminary report on the Educational Qualifications of School Physicians which has been prepared under the Chairmanship of C. C. Wilson, M.D., of New York, N. Y.

Progress reports were received by the committee on the Educational Qualifications of Professional Personnel in Sanitation, on the Qualifications of Public Health Nurses, of Public Health Nutritionists, and of Public Health Statisticians.

On the recommendation of Henry F. Vaughan, Dr.P.H., Referee, it was voted to defer action on the preparation of a report on crippled children's specialists for the present.

The Committee on Professional Education considered a request from the American Association of Colleges of Pharmacy that the A.P.H.A. define the position of pharmacy among the public health professions.

Further consideration was given to a resolution regarding levels of compensation commensurate with professional qualifications.

The Committee on Professional Education considered a possible survey of the field of graduate education in public health and voted to continue the present liaison with the Council on Medical Education and Hospitals of the American Medical Association. It was the opinion of the committee that steps should be taken immediately to secure a greater uniformity in graduate degrees in public health. Attention was called to the fact that during the academic year 1941-1942, 27 different public health degrees were granted. Inquiry was made of the Association of Schools of Public Health as to steps that were being taken to correct this situation. The committee also considered the possible certification of schools of public health.

ISABEL B. LANDY
Associate Secretary

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

' Health Officers Section

Vernon F. Anderson, M.D., D.P.H., Government Medical Service, Belize, British Honduras, Senior Medical Officer

Francis H. Cole, M.D., Memphis and Shelby County Health Dept., Oakville, Tenn., Director, Div. of Tuberculosis Control

C. J. Fisher, M.D., M.P.H., City Hall Bldg., Tuscaloosa, Ala., Tuscaloosa County Health Officer

Frank F. Furstenberg, M.D., Bay Area Health Center, Valparaiso, Fla., P.A. Surgeon (R), U. S. Public Health Service and Physician, State Health Dept.

Dr. G. Harold K. Gentle, M.P.H., St. Georges, Grenada, British West Indies, Medical Officer in charge of Health Centers

Gunnar Gundersen, M.D., 1836 South Avenue,

LaCrosse, Wis., Member, State Board of Health

Clarence E. Houston, City Bldg., Washington, Pa., City Health Officer

Benjamin Ron Monroy, Av. Mexico No. 328, Tepic, Nay, Mexico, State Health Commissioner, Federal Dept. of Health

James P. Moon, M.D., 44 Vine St., Winchester, Tenn., Director, Franklin and Coffee County Health Dept.

Fritz Plotke, M.D., M.P.H., State Hospital, Chicago, Ill., Public Health Adviser, State Dept. of Public Welfare

Joseph J. Saia, M.D., Hoopa General Hospital, Hoopa, Calif., Physician, Senior Grade, U. S. Indian Service

Alice M. Waterhouse, M.D., 3557 86th St., Jackson Heights, L. I., N. Y., Junior Health Officer, New York City Dept. of Health

Laboratory Section

William F. Bloom, 224 81st St., Brooklyn, N. Y., Jr. Bacteriologist, Sea View Hospital
 Helen B. Brumbaugh, M.S., 4609 Bayard St., c/o Mrs. Price, Apt. 4, Pittsburgh, Pa., Serological Technician, Pittsburgh Public Health Lab.

Margaret J. Carlson, 824 West Ionia, Lansing, Mich., Bacteriologist, State Dept. of Health Labs.

Ivory L. Clinton, State Dept. of Health Lab., Lansing, Mich., Bacteriologist

Adrien S. DuBois, Richards Chemical Works, 190 Warren St., Jersey City, N. J.

Louis C. Felger, City Health Labs., San Antonio, Tex., Laboratory Director

Kathleen L. Gay, P. O. Box 727, Selma, Ala., Assoc. Bacteriologist, State Dept. of Health Laboratories

Lieut. Irving J. Greenblatt, Sn.C., Camp Stoneman Hospital, Calif., Asst. Chief, Laboratory Service, Army of U. S.

Laura M. Huntley, 312 W. Grand River, East Lansing, Mich., Bacteriologist, State Dept. of Health

Mildred Jefferies, State Dept. of Public Health, Montgomery, Ala., Assoc. Bacteriologist, Bureau of Labs.

Arden H. Killinger, Ph.D., Parke, Davis & Co., Detroit, Mich., Sr. Research Virologist, Research and Biological Labs.

Lieut. Peter J. Knaus, Sn.C., 4322 5th Ave., So., Minneapolis, Minn., Sanitary Officer, 279th Station Hospital, Camp Bowie, Tex.

Major Clarence F. Nave, Sn.C., Station Hospital, Fort Benning, Ga., Asst. Chief of Laboratory Service

Harry Pearse, M.S., State Sanatorium, Wal-lum Lake, R. I., Laboratory Director

Lieut. William S. Proudfit, Sn.C., 320 South 15th, Lincoln, Nebr., Sr. Bacteriologist, State Health Dept.

Hermann Sommer, Ph.D., Hooper Foundation, U. C. Medical Center, San Francisco, Calif., Asst. Professor of Medical Research

James L. Terrell, 4080 Detroit St., Beaumont, Tex., Director, Jefferson County Health Unit Laboratory

Mae L. Watts, M.S., 406 No. Ardmore Ave., Los Angeles, Calif., Bacteriologist, State Dept. of Public Health

Paul A. Wolf, Ph.D., 2010 Ashman St., Midland, Mich., Biochemist, Dow Chemical Co.

Vital Statistics Section

Mary C. Macdonald, 156 Allen Place, Hartford, Conn., Secty. of Tumor Record Registry, Cancer, Div., State Dept. of Health

Engineering Section

Leon S. Blankenship, 2736 E. Magnolia Ave.,

Knoxville, Tenn., Director, Div. of Sanitation, Knoxville-Knox County Health Dept.

Charles E. Cotton, Jr., District Health Unit, Twin Falls, Ida., Milk Sanitarian, State Dept. of Public Health

Vernon P. Crockett, 603 BMA Bldg., Kansas City, 8, Mo., Asst. Engineer (R), U. S. Public Health Service

Morton S. Hilbert, 818 John St., Apt. 1, Sault Ste. Marie, Mich., Sanitary Engineer, Chippewa County Health Dept.

Ladislaus T. Jodaitis, 458 State Office Bldg., Madison, Wis., Asst. Engineer (R) U. S. Public Health Service, (Assigned to State Board of Health)

James A. King, Jr., 1613 Pineola Ave., Kingsport, Tenn., Actg. Jr. Sanitation Consultant, Sullivan County Health Dept.

Capt. Wilburn H. Kittrell, Sn.C., New Orleans Staging Area, New Orleans, La., Survey Unit, Army of the U. S.

William B. Schreeder, Box 58, LaFayette, Ga., Public Health Engineer, Walker County Health Dept.

Charles T. Starkey, State Board of Health, Houston, Miss., District Milk Sanitarian

Norman S. Stearns, 16 Fuller St., Brookline, Mass., Sr. Sanitary Engineering Aide, State Dept. of Public Health

Rulon S. Tueller, Bannock County Health Unit, Pocatello, Ida., Sanitarian

Leonard P. White, Basement, City Hall, Houston, Tex., Sanitary Engineer, Water Div., Utilities Dept.

Charles L. Wood, Box 175, Marlboro, Md., Sanitary Engineer, State Health Dept.

Industrial Hygiene Section

Bruno Allary, M.D., D.P.H., Roberval, P.Q., Quebec, Canada, Medical Officer of Health

Mary Grebas, R.N., 3501 Garrison Blvd., Baltimore, 15, Md., Industrial Nurse, Bendix Radio

William Brice Pinder, East Bay St., Nassau, Bahamas, Member, Board of Health

Food and Nutrition Section

Richmond K. Anderson, M.D., Calle Viena, 26, Mexico, D. F., Mexico, Staff Member, International Health Div., Rockefeller Foundation

W. Hazel Bean, M.S., Reg. Office, State Health Dept., Jackson, Tenn., Regional Nutrition Consultant

Lola T. Dudgeon, M.S., University of Arizona, Tucson, Ariz., Extension Nutritionist

Henry R. Kraybill, Ph.D., 59 East Van Buren, Chicago, Ill., Director, Dept. of Scientific Research, American Meat Inst.

Leslie J. Rosenberg, 4014 Kansas Ave., N.W.,

Washington, D. C., Food Inspector and Bacteriologist, D. of C. Health Dept.

Maternal and Child Health Section

Robert J. O'Neil, D.M.D., 1208 Faithful St., Victoria, B. C., Canada, Provincial Clinician, B. C. Dept. of Health

Ruth Tartakoff, M.S., Childrens Bureau, U. S. Dept. of Labor, Washington, D. C., Regional Medical Social Consultant

Mildred Van Cleve, M.D., 4509 Edgewood Place, Riverside, Calif., Pediatrician, State Dept. of Public Health

Public Health Education Section

George R. Bedinger, M.A., 2944 Macomb St., N.W., Washington, D. C., Chief, Health and Sanitation Section, Federal Public Housing Authority

Leon M. Childers, D.D.S., Manhattan Beach Coast Guard Sta., Brooklyn, N. Y., P.A. Dental Surgeon (R), U. S. Public Health Service

Mary L. Gladish, 262 Pulaski St., Lawrenceburg, Tenn., Student, Univ. of North Carolina, School of Public Health

Sister Marie B. Masterson, 8200 W. Outer Dr., Detroit, Mich., Sisters of Mercy, Hospital Division

Joseph J. Obst, D.D.S., 798 E. 34th St., Brooklyn, 10, N. Y., Dentist

Julius A. Olean, M.D., P. O. Box 553, Midland, Tex., Director, Midland-Ector-Howard County Health Unit

M. Virginia Parsons, R.N., P. O. Box 547, Savannah, Ga., Assoc. Health Education Consultant, U. S. Public Health Service

Ruth D. Rains, 1014 Monroe St., Charleston, Ill., Student of Public Health Education, Univ. of North Carolina

Lucretia A. Saunders, 520 E. 54th St., Indianapolis, Ind., Public Health Educator, State Board of Health

Gordon H. Sears, M.A., 9108 Burning Tree Rd., Bethesda, 14, Md., Medical Care Adviser, U. S. Public Health Service

Agnes H. Thomson, 128 Spadina Rd., Toronto, Ont., Canada, Medical Officer, Provincial Dept of Health

Lieut. Julius H. Winer, M.C., 480 Lexington Ave., New York, 17, N. Y. Chief of Urological and Laboratory Dept., Armed Forces Induction Station

William E. Woods, Driskill Hotel, Austin, Tex., Health Education Consultant, State Health Dept.

Public Health Nursing Section

Marie R. Audet, R.N., 120 Grande Allee, Quebec, P. Q., Canada, Social Service

Worker, Div. of Venereal Diseases, Ministry of Health

Francis Frazier, R.N., 706 Huntington Ave., Boston, Mass., Student, Harvard School of Public Health

Edith Hetteima, City Health Dept., Portsmouth, Va., Venereal Disease Control Nurse

Ida McRoberts R.N., M.A., 131 S. Barry St., Olean, N. Y., Supervising Nurse, Cattaraugus County Dept. of Health

Della M. Poe, 210 E. Kathleen, Sikeston, Mo., Senior Nurse, Southeast Missouri Health Service, Inc.

Esther Porter, 829 Hampton Ave., Toledo, Ohio, Asst. Director of Nurses, City Board of Health

Ethelwyn H. Saxild, R.N., City Hall, Richmond, Calif., Supervisor of Public Health Nursing, Richmond Health Dept.

Mildred Tuttle, M.S., 216 N. Mulberry, Marshall, Mich., Consultant in Nursing Education, W. K. Kellogg Foundation

Epidemiology Section

J. Franklin McVeigh, M.D., M.P.H., 204 Plymouth Ave., S., Rochester, N. Y., Asst. District Health Officer, State Health Dept.

Elsmere R. Rickard, M.D., M.P.H., State Dept. of Health, Univ. Campus, Minneapolis, Minn., Director, Influenza Laboratory

School Health Section

Lewis S. Harris, Sr. High School, Orchard St., Belmont, Mass., Director, Dept. of Health and Physical Education, Belmont Schools

Esther T. Melrose, R.N., 1005½ W. Mullen, Waterloo, Iowa, School Nurse, Waterloo Public Schools

Unaffiliated

William T. Clark, M.D., 317 Hayes Bldg., Janesville, Wis., Member, State Board of Health

Capt. Harold M. Deane, V.C., APO 862, Postmaster, New York, N. Y., Veterinary Corps, U. S. Army

Stephen E. Gavin, M.D., 104 S. Main St., Fond du Lac, Wis., Member, State Board of Health

Lillian D. Long, Ph.D., 40 W. 67th St., New York, N. Y., Psychometrician, Merit System Study, American Public Health Assn.

Albert E. Rector, M.D., 103 W. College Ave., Appleton, Wis., Member, State Board of Health

Hildegard Wagner, 340 E. 52nd St., Apt. 3D, New York, 22, N. Y., Field Director, Local Health Preparedness Committees, New

York State Health Preparedness Commission

Harrison A. Walker, M.D., 735 Penn Ave., N.E., Atlanta, Ga., Senior Surgeon (R), U. S. Public Health Service and Regional Medical Officer, Office of Civilian Defense

DECEASED MEMBERS

John W. Alvord, Chicago, Ill., Elected Member 1899, Charter Fellow 1922, Engineering Section

A. T. McCormack, M.D., Louisville, Ky., Elected Member 1919, Charter Fellow 1923

Orville H. Brown, M.D., Arcadia, Calif., Elected Member 1937

Leo F. Hall, M.D., Helena, Mont., Elected Member 1920

WILLIAM J. RYAN, M.D., Pomona, N. Y., Elected Member 1934, Maternal and Child Health Section

LESLIE T. WEBSTER, M.D., New York, N. Y., Elected Member 1935, Elected Fellow 1940, Epidemiology Section

ROBERT S. WESTON, Boston, Mass., Elected Member 1896, Charter Fellow 1922, 40 year member, 1938, Engineering Section

CORRECTION

On page 893 of the *Journal* for July, there is an outline of Bristol's method of treating verminous heads. It is stated in the item that lethane is a derivative of arsenic preparations. This is an error. Lathane 384 Special, according to the manufacturers, Rohm & Haas Company, Philadelphia, Pa., is a synthetic organic chemical product widely used as an insecticidal agent in household and industrial sprays. It contains no arsenic nor is any arsenic compound used in the process of its manufacture.

Further references to the use of this

method for controlling the head louse can be found in the *British Medical Journal*, April 11, 1942, volume 1, page 464, and in a memorandum on Control of Head Lice issued in 1943 by the British Ministry of Health, No. 230A.

JOURNALS URGENTLY NEEDED

It will be much appreciated if readers will send spare copies of the July, 1941, January, 1942, January, 1943, and March, 1943, issues of the *American Journal of Public Health* to the Stock Clerk, American Public Health Association, 1790 Broadway, New York 19, N. Y.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

THE MERIT SYSTEM COUNCIL OF WEST VIRGINIA ANNOUNCES EXAMINATIONS FOR THE FOLLOWING POSITIONS IN THE WEST VIRGINIA STATE HEALTH DEPARTMENT

<i>Position</i>	<i>Salary</i>
Public Health Nurse (Class A)	\$1,680-\$1,980
Public Health Nurse (Class B)	1,500-1,860
Public Health Nurse Trainee	1,380-1,500
Graduate Nurse	1,380-1,620
Junior Engineer	2,160-2,640
Chemist	1,620-2,100
Sanitarian	1,500-2,100
Sanitarian Trainee	1,200-1,500
Junior Bacteriologist	1,920-2,400
Junior Serologist	1,920-2,400
Technical Laboratory Assistant	1,500-2,100

Age limits and residence in West Virginia have been waived in consideration of applicants for these positions. Appointments may also be made at a salary above the minimum. Applications will be ac-

cepted continuously and examinations given whenever enough applications are filed to assure adequate competition. Persons interested should make application to the Merit System Council, 212 Atlas Building, Charleston, W. Va.

Announcement is made of the following examinations to be held by the State Personnel Board, Seattle, Wash., for positions in the State Department of Health and County Health Departments:

<i>Position</i>	<i>Salary Range Entrance Maximum</i>	
Bacteriologist B	\$160	\$190
Laboratory Helper D..	120	140
Laboratory Assistant C	140	160
Laboratory Technician	140	170
District Public Health Officer V	380	440
Public Health Nurse B	160	190
Asst. Venereal Disease Investigator B	160	190
General Sanitarian A ..	190	220
Milk Sanitarian A	190	220
Chief of Public Health Education	280	320
Senior Milk Sanitarian..	220	250
Obstetric Consultant VI	440	500
Pediatric Consultant VI	440	500
Senior Bacteriologist A	190	220

Council of Social Agencies in large Midwestern city is seeking person to fill position of assistant secretary in its health division. Responsibilities include coordinating, planning, and promoting of adequate community health services. Involves working with medical and health agencies and organizations and with committees. Beginning salary \$3,000. Applications should indicate training and experience and references. Box R, Employment Service, A.P.H.A.

Wanted: Two physicians, immediate appointment, full-time venereal disease clinician, conduct several small clinics rotating schedule. Experience preferred.

Salary \$3,600 plus actual expense not to exceed \$1,200. Write State Health Department, Santa Fe, New Mexico.

Wanted: Laboratory technician, tuberculosis hospital. 130-150 beds. Salary \$175 per month and full maintenance. Opportunity to do research. Nice surroundings, good living quarters. Write Dr. Paul D. Crimm, Boehne Hospital, Evansville, Ind.

Physician—public health pediatrics. To assist director of maternal and child health in large California County Health Department. Major duties, conducting of infant and preschool health conferences and school examinations. Beginning salary \$350 and travel allowance. California license required. Training and experience in pediatrics or public health or both. Immediately available. Address William C. Buss, M.D., Kern County Health Department, Bakersfield, Calif.

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$3,900-\$4,500 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Tuberculosis Association in large eastern city will accept applications for position on staff as statistical research secretary. Requirements: basic training in vital statistics, ability to plan and carry out statistical studies in the field of public health. One month's vacation. Five day week, with occasional work on Saturdays. Address Box C, Employment Service, A.P.H.A.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in coöperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Linck, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

Wanted: Competent, thoroughly trained bacteriologist, woman or draft exempt man to take complete charge of splendidly equipped small industrial laboratory. Connecticut location, country environment, pleasant surroundings, excellent working and living conditions. Must have Ph.D. training or equivalent. Apply Box D, Employment Service, A.P.H.A.

Merit System for Personnel Administration in Delaware will set examinations for 3 positions in the Delaware State Board of Health shortly. The positions open for examination, together with the beginning salaries, are: Deputy State (County) Health Officer (\$3,800), Pediatrician (\$3,600), and Medical Social Consultant (\$2,400).

These examinations will be unassembled, but successful candidates will be expected to appear in Delaware for an oral interview which will be a weighted part of the examination. Appointments may be expected soon after the examinations are conducted.

Information and specifications as prepared for each position may be secured by communication with the Merit System Supervisor, P. O. Box 1911, Wilmington, Del., and application for examination must be made on the official form.

The Department of Health, New Jersey, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual opportunities for gaining experience in occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Physicians interested in these positions should write to the Department of Health, Trenton, N. J.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5.00 per month each year until \$135 has been reached. To this

basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus maintenance. Apply to Dr. G. F. Burhardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Woman bacteriologist for midwestern research organization. Industrial experience not necessary. Applicant should have had basic training in bacteriology. Apply Box P, Employment Service, A.P.H.A.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Wanted: Public health statistician for large California County Health Department. College degree with training in statistics. Salary \$200. Position open. Address William C Buss, M.D., Kern County Health Department, Bakersfield, Calif.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK 19, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

Physician, M.D. Yale, with private practice industrial medicine. Age 39 and draft exempt. Seeks opportunity as public health physician. A-505

Woman physician, well prepared in pediatrics, M.S.P.H. DeLamar Institute, Columbia University. 1943, seeks employ-

ment in the field of maternal and child health, preferably administrative in pediatrics. Excellent references. A-507

Physician, M.D. University of Arkansas, M.P.H. Harvard, experienced as county health officer. Age 35. Will consider position as city or county health officer or director of a bureau. A-506

NEWS FROM THE FIELD

NEW APPOINTMENTS TO STAFF OF THE CHILDREN'S BUREAU

Alice Brackett has been appointed as assistant director of the nursing unit in the Division of Health Services of the Children's Bureau. Since October 1, 1939, she has been regional consultant nurse for the Children's Bureau in San Francisco.

Joy B. Stuart has succeeded Miss Brackett as regional consultant nurse in the San Francisco office. Miss Stuart was consultant nurse in maternal and child health in the State Department of Health in Utah for several years and recently organized the nursing services of the War Relocation Authority.

Lucile Perozzi, former director of public health nursing in the State of Oregon, has been appointed as regional consultant nurse for the Children's Bureau in the Midwest area.

Ruth Doran, former regional consultant nurse for the Children's Bureau in the Southern area, has been appointed as consultant nurse in maternal and child health and nurse midwifery.

Hattie Hemschemeyer, assistant director of Maternity Center Association, New York, N. Y., and lecturer in nursing education at Teachers College, has been appointed as part-time consultant to the Children's Bureau in special problems of maternity nursing and nurse midwifery.

NEW YORK CITY CERTIFIED MILK TO BE PASTEURIZED

The New York City Board of Health recently passed the following amendment to Section 156 of the city Sanitary Code restricting the sale of raw certified milk and of certified raw milk products to persons presenting a phy-

sician's prescription. The new regulation will become effective January 1, 1944.

"Regulation 15. Sale of certified milk, skimmed milk or cream (raw) on physician's prescription only. No certified milk, skimmed milk or cream, other than 'Certified Milk (Pasteurized),' 'Certified Skimmed Milk (Pasteurized),' or 'Certified Cream (Pasteurized),' shall be sold or distributed in the City of New York except in those cases where a physician's statement, prescribing unpasteurized (raw) certified milk, skimmed milk or cream, is filed by the purchaser with the milk dealer. The physician's statement shall bear the date of issuance, the name and address of the consumer and shall be valid for one year from the date of issuance. Such statement shall be kept on file by the milk dealer and shall be open at all times to inspection by a representative of the Department of Health."

Health News, New York State Dept. of Health, 20, 30 (July 26), 1943.

DR. BLACKERBY APPOINTED KENTUCKY STATE HEALTH COMMISSIONER

The Kentucky State Board of Health has announced the election of Philip Earle Blackerby, M.D., who has served for years as Assistant State Health Commissioner, to the position of Secretary and State Health Commissioner to succeed Arthur T. McCormack, M.D., who died on August 7. Dr. Blackerby is a graduate of the University of Louisville School of Medicine in 1904. He joined the American Public Health Association in 1933 and is associated with the Health Officers Section.

DR. HUTCHESON APPOINTED COMMISSIONER OF HEALTH IN TENNESSEE

R. H. Hutcheson, M.D., who has served for some years as Assistant Commissioner of Health in Tennessee, was recently appointed Commissioner of Health by Governor Prentice Cooper,

succeeding W. Carter Williams, M.D., who has been called to military duty and commissioned a Lieutenant Colonel in the Medical Corps of the U. S. Army.

Dr. Hutcheson is a graduate of the University of Tennessee, M.D., 1930, and received his C.P.H. from Johns Hopkins School of Hygiene and Public Health in 1934.

MARYLAND STATE COURT OF APPEALS
SUPPORTS BALTIMORE CITY
HOUSING ORDINANCE

The Maryland Court of Appeals recently handed down a decision approving the constitutionality of Baltimore's health ordinance relating to housing. The ordinance was passed in 1941, according to the *Baltimore Sun*, in response to a strong public sense of outrage against slum conditions in Baltimore, and was designed to strengthen the hand of the Health Department in enforcing minimum housing standards. A case under the law was appealed on the ground that the ordinance was unconstitutional and gave illegal power to the Health Commissioner.

In its decision the Court of Appeals declared that "The only purpose of the ordinance is to protect and preserve the health of the people of Baltimore," and that "the city has the power under its charter to preserve the health of the city and to prevent and remove nuisances. The exercise of charter powers by a city is not discretionary but is a duty."

Baltimore Health News for August publishes the decision in full.

ROYAL COLLEGE OF PHYSICIANS ELECTS
MEDICAL OFFICERS OF HEALTH TO
FELLOWSHIP

Announcement recently has been made that the Royal College of Physicians in London has elected to Fellowship Dr. James Macintosh of Glasgow, Dr. Robert Hughes Parry of Bristol, and Dr. John E. Gordon, Professor of

Preventive Medicine and Public Health at Harvard University Medical School, Boston, Mass. This recognition of health workers with Fellowships is said to be extraordinary in the history of the Royal College.

PERSONNEL CHANGES IN THE TERRITORIAL BOARD OF HEALTH, HONOLULU

As of June 5, 1943, Dr. Marion F. Haralson of the staff of the U. S. Public Health Service, who had been Commissioner of Public Health, was transferred from Honolulu, and on June 25 Charles L. Wilbar, Jr., M.D., was appointed to succeed him. A recent session of the Territorial Legislature has changed the title of the position from Commissioner of Public Health to President of the Board of Health.

Dr. Wilbar was released from active duty as a Major in the Medical Corps of the U. S. Army to accept this position. Previous to entrance into the Army he was Director of the Bureau of Maternal and Child Health of the Territorial Board of Health.

During the interim Richard K. C. Lee, M.D., Deputy Commissioner of Public Health, was in temporary charge of the department. He now serves as executive officer under Dr. Wilbar.

SOUTHERN BRANCH, A.P.H.A.

The Southern Branch of the American Public Health Association will have no formal meeting in 1943, but will have a meeting of the officers of the Association and the Governing Council.

CORRECTION

In the report "Check Anthrax" in the July *Journal*, page 855, it was erroneously stated that "it is regrettable that the U. S. Public Health Service has ceased to make anthrax in this country reportable to them." The facts are that detailed case records are no longer required, but weekly numerical reports are still received from the

states. The impression of certain individuals, referred to on page 856, that anthrax was no longer a particular hazard, grew rather from the fact that Department of Agriculture regulations regarding the importation and treatment of animal by-products, designed to prevent the dissemination of anthrax, were discontinued in 1940.

COURTENAY DINWIDDIE DIES

Courtenay Dinwiddie, sociologist and general secretary of the National Child Labor Committee, died September 13 in New York of a heart attack at the age of 60. Formerly director of health programs under the American Child Health Association and under the Commonwealth Fund, Mr. Dinwiddie was also consultant on child hygiene for the New York City Department of Health and at one time a teacher of community organization at Johns Hopkins University. He has been a member of the A.P.H.A. since 1916 and a Fellow since 1922.

PERSONALS

Central States

ERWIN C. CARY, M.D., of Reedsville, Wisc., has been reappointed Health Officer for the Village of Reedsville and also for the towns of Rockland and Franklin. He was recently re-elected President of the Manitowoc County Health Officers' Association.

VIDA H. GORDON, M.D., M.P.H.,† Director of the Sanilac County (Mich.) Health Department since June, 1941, has been appointed Director of Crippled Children Activities in Arkansas, with headquarters in Little Rock. Dr. Gordon was recently elected President of the Sanilac County Medical Society.

WILLIAM T. GROVE, M.D., of Eureka, Kans., has been appointed Health Officer of Greenwood County, to succeed WALTER S. MOONLIGHT, M.D., of Eureka, resigned.

ALICE M. HEATH, C.P.H.,† formerly Health Education Consultant for the Wisconsin Anti-Tuberculosis Association, has accepted a position as Director of Health Education of the Peoria County Tuberculosis Association, Peoria, Ill.

SAMUEL N. MALLISON, M.D.,† of El Dorado, Kans., has resigned as Health Officer of Butler County, to become Superintendent of the Southern Illinois Health District with offices in Harrisburg, Ill.

Eastern States

MARY M. ATCHISON, M.D., M.P.H.,† of Concord, N. H., has been appointed Acting State Health Officer of the State Department of Health of New Hampshire, to act during the leave of ALFRED LEO FRECHETTE, M.D., M.P.H.,† State Health Officer.

AMELIA H. GRANT, R.N., who has been Director of the Bureau of Nursing in the New York City Department of Health since 1928, retired recently. Commissioner E. L. Stebbins stated that no successor has yet been named. Miss Grant has been associated with the Henry Street Visiting Nurse Service, with the Department of Nursing Education at Teachers College, Columbia University, with the Yale School of Nursing, New Haven, and the Bellevue-Yorkville Health Demonstration. Miss Grant has twice been President of the N.O.P.H.N.

ROSE KOSHETZ† (M.S. in public health, Yale, 1928) has enlisted in the U. S. Army and after completing officer training expects to receive a commission. She has enlisted for overseas service and expects to return to the Middle East where she spent four years working as a dietitian in a large hospital in Palestine.

* Fellow A.P.H.A.

† Member A.P.H.A.

FREDERIC W. NORDSICK,* who for 5 years has been associated with the American Institute of Baking, New York, N. Y., has resigned to accept an appointment in the Department of Applied Research of Standard Brands, Inc., at the home office, New York City.

ANTHONY J. SPARTA, M.D., has been named Health Officer of Easton, Pa., succeeding the late REUBEN S. RAUB, M.D., who died May 28.

DONALD K. TRESSLER, PH.D.,* since 1933 Chief of Research and head of the Division of Chemistry, New York State Agricultural Experiment Station, Geneva, N. Y., has joined the staff of the General Electric Company. He will be concerned chiefly with research on refrigeration and the freezing preservation of foods, working in the laboratories at Bridgeport, Conn.

HELEN M. WALLACE, M.D., M.P.H., who completed the course at the Harvard School of Public Health in May, has been appointed Junior Health Officer in the New York City Department of Health.

Southern States

MARYLAND E. B. BYRNE, M.D., has been appointed Director of Maternal and Child Health of the Dade County Health Unit, Miami, Fla.

TURNER E. CATO, M.D.,† has been appointed Director of the Dade County Health Unit, Miami, Fla., following the recent resignation of THOMAS H. D. GRIFFITTS, M.D., D.P.H.†

ELIZABETH HARVEY, of Silver Springs, Md., has been appointed Health Secretary to the Council of Social Agencies of Washington, D. C. and vicinity, effective September 15.

GLEN J. HOPKINS,† formerly Assistant Public Health Engineer of the Mis-

souri State Health Department, has been commissioned as Past Assistant Engineer of the U. S. Public Health Service Reserve, and has been assigned to the South Dakota State Health Department as Director of the Division of Public Health Engineering. Mr. Hopkins also served as Secretary of the Missouri Public Health Association, and his successor as Secretary of this A.P.H.A. affiliated society is J. WARREN SMITH, Assistant Public Health Engineer, State Health Department, Jefferson City, Mo.

GORDON E. MCCALLUM,† Sanitary Engineer, U. S. Public Health Service, who has been Acting Chief of the Sanitary Engineering Section of the Medical Division of the Office of Civilian Defense since January, 1943, has been designated Chief Sanitary Engineer in charge of the Section. Mr. McCallum was assigned to the Medical Division in 1941 as Regional Sanitary Engineer for the Third Civilian Defense Region (Maryland, Virginia, Pennsylvania, and the District of Columbia) and the States of Ohio and West Virginia, and later was made Assistant Chief Sanitary Engineer.

HARCOURT A. MORGAN, JR., M.D.,† of Lewisburg, Tenn., head of the Bedford County Health Unit, has been placed in charge of a seven county area including the six adjacent counties of Grundy, Franklin, Warren, Bedford, Marshall, Moore, and Coffee, with headquarters at Manchester, Tenn.

JOHN E. OFFNER, M.D., of Weston, W. Va., was recently appointed State Health Commissioner.

B. M. PRIMER, M.D., M.P.H.,* formerly Health Officer in the Amarillo, Tex., Department of Health, is now Lieutenant Colonel, M.C., U.S.A., and is Commanding Officer of the

Immediate Wartime Outlook and Indicated Post-War Conditions with Respect to the Control of the Venereal Diseases*

THOMAS B. TURNER, LT. COL., M.C., F.A.P.H.A.

*Chief, Venereal Disease Control Branch, Preventive Medicine Division,
Office of The Surgeon General, U. S. Army, Washington, D. C.*

I WISH to refer to what has been accomplished in venereal disease control in the Army since mobilization, mention briefly the tasks that lie immediately ahead, and then discuss some of the things we have learned that might with profit be carried over into the post-war management of this problem.

In general, the venereal disease situation in the Army has steadily improved since the first months of mobilization. The venereal disease rate for 1940 was 42.5 per 1,000. While current rates are not entirely comparable because of certain changes in administrative procedure, the rates for the past few months for infections acquired after entry into the service have been in the neighborhood of 25 per 1,000 per year. The syphilis rate has been under 5. When

these rates are further computed according to race, age, and sex they appear to be no higher than the attack rates for comparable groups of civilians during the past decade. In other words, there is no evidence that a young man in the Army today stationed in the Continental United States is subjected to a higher risk of venereal infection than he would be as a civilian.

Even more striking, and perhaps more significant, are the data on days lost from duty because of venereal disease. In 1940 each 1,000 men lost a total of 1,278 days; current rates are at a level of 368 days lost per year. For each million men under arms this represents a saving over the rate prevailing in 1940 in hospital costs alone of approximately \$4,000,000 each year—quite a saving considering the size of our present Army. Continuing advances in preventive measures, and in new methods of treatment, give promise

* Presented at a meeting of the New York State Committee on Tuberculosis and Public Health, June 3, 1943.

of further reducing the non-effective days.

Since October 1, 1942, through June, 1943, over 55,000 men infected with venereal disease as civilians have been taken into the Army, hospitalized until non-infectious, given adequate treatment under decent conditions, and turned over as functioning members of the Army. Over 20,000 of these have been individuals with syphilis.

Abroad, in some areas where there are large bodies of troops, the venereal disease rate has been very low; in other theaters of operation it has been high. The latter areas are receiving concentrated attention and we can only hope that our efforts will bear fruit.

The accomplishments thus far may be attributed we believe, to the recognition of venereal disease as primarily a medical problem, to the unfailing support of the control program by those in places of highest authority, and to the effective coöperation received from civilian authorities and community groups. I do not wish to give the impression that we are satisfied with the present situation. Indeed, the goal has been set at a level of rates much below those obtaining at present.

What tasks lie immediately before us?

First, we must afford protection to our troops abroad. I shall not dwell on this except to say that the problem is receiving close attention.

Second, much greater effort must be made by all concerned, both military and civilian, to bring the rate for Negro troops more in line with the rates for the Army as a whole. Recent experience indicates that this is not an impossible task.

Third, research—in the laboratory, in the hospital, in the field—must be pressed forward with all possible speed. Competent work is in progress under sponsorship of the Committee on Medical Research of the Office of Scientific Research and Development, on prophylaxis and on new therapeutic agents. We

need better epidemiological data and improved diagnostic tools.

Fourth, we must expand our educational efforts, particularly as directed to the young women of the community. Progress has been made in teaching the soldier to understand and avoid the hazards of venereal disease. The material assistance in this aspect of the program of the U. S. Public Health Service, the American Social Hygiene Association, many state health departments, and other groups is gratefully acknowledged. The responsible citizens of the community, too, are much better informed than they used to be. But this educational process is not reaching down to the young girls who are the companions of our soldiers. They give the impression of being sophisticated and knowledgeable in these matters, but actually they are sadly lacking in useful information.

We are often criticised on the grounds that instruction in sex hygiene and venereal diseases tends to lead to sexual promiscuity. I know of not the slightest evidence to support that view. Moreover, it is less than just to assume that fear of venereal disease is the principal reason that men and women adhere to the accepted moral code. We need not be afraid of the effects of knowledge concerning sex hygiene and venereal disease; for knowledge will carry with it an understanding and an orientation from which only good can flow. This is a job for all of us, the armed forces, health departments, and voluntary groups.

Fifth, the gains made against organized prostitution must be maintained. Prostitution is a hardy weed and constant attention is required to keep the gardens reasonably clean. It can be done only with and through the full support of the citizens of the community. Law enforcement and investigating machinery must be adequate of

course, but we have seen few communities that could not inaugurate and maintain a satisfactory program when the substantial citizens willed it so. It is not within my province to debate the moral issues involved, but it is my business to protect soldiers from venereal disease, and it has been amply demonstrated during this war period, if further evidence is necessary, that prostitution is a potent breeder of these diseases.

We have repeatedly to answer questions based on skepticism concerning the value of the repression program. Many worthy citizens believe that men must have prostitutes, that prostitutes can be made safe and sanitary by medical control, and that segregation and regulation rather than repression is the way to handle this problem. These beliefs are based on misinformation. It is not anticipated that prostitution will be wiped out any more than we expect that malaria will be eradicated in any foreseeable time, but it is certain that prostitution can be reduced in extent. To date the results have been far from discouraging and no one in authority would wish to return to the conditions that existed in many communities in the early days of mobilization.

There are numerous instances which lead one to believe that a more sensible approach is being made to the prostitution problem. While the prostitute herself is certainly not without blame, it is the third party in the boy-girl-facilitator combination that makes prostitution dangerous to the health of soldiers. It is a question of mathematics. A girl, regardless of how depraved her morals or how strong her desire for money, can expose relatively few soldiers without the aid, whether wittingly or not, of so-called facilitators, such as madams, taxi drivers, bellhops, proprietors and owners of cheap hotels and rooming houses. With the assistance of these facilitators, who are often

financially interested, she may have the opportunity of exposing many more individuals, thus greatly increasing the number of men subjected to the risk of infection. It is obvious that repressive measures should be directed to the apprehension of the facilitator, and not to the medically unprofitable activity of jailing prostitutes.

Finally, we are faced with the problem of the sexually delinquent young girl. This is not a prostitution problem and should not be confused with it. It is not even primarily a law enforcement problem, but a social and a medical one. I do not know the solution for it and I am not sure that anyone else does. But it is imperative that facts be accumulated quickly, in the hope that these might point the way to a more rational approach to the problem.

It is very disturbing to see misguided young girls, often bedraggled and undernourished, without family or friends, caught up in the prostitution repression program—jails and courts—when the whole situation might be handled by a stern father and a good doctor. Here is an opportunity for wise community leadership. The development of detention houses with facilities for medical treatment and possible rehabilitation is wholly sound. But something in addition is required. These girls need a flag around which to rally. They need to have some job to do and a feeling of personal responsibility toward the war effort. Possibly the expansion of community organizations of one sort or another to include these young girls in a democratic fashion may afford a partial answer. In any case, the energies of law enforcement personnel should not be diverted from the important and difficult job of the repression of true prostitution; that would please only those interests that profit from prostitution.

From this wartime experience in venereal disease control what lessons

are to be learned that may be useful when the time comes to reestablish our peacetime society? What new approaches to this old problem may be indicated in order to extend the civilian program so gallantly launched a few years ago?

First, I believe we should more fully exploit our medical resources in the attack on these diseases. No one will deny that moral factors play an influential rôle in the occurrence of syphilis and gonorrhea. But it is equally obvious that applications of the principles of epidemiology will lessen the toll of venereal disease quite out of proportion to the results obtained by the moral approach alone.

Army experience is emphasizing the value of prompt diagnosis and prompt treatment to render the individual non-infectious. The value of contact investigation in discovering sources of infection and, more important perhaps, *places* where infection is acquired; the value of prophylaxis as a preventive measure; the importance of obtaining accurate data on the distribution of disease to the end that control measures may be more sharply focused.

The best results can be obtained only by greater utilization of specially qualified medical personnel. A most important step was taken by the War Department when it authorized the assignment of qualified venereal disease control officers to large camps, to the major headquarters of the Army, and to all theaters of operation. Merged into the regular medical service of the Army, the influence of this handful of specialists is far-reaching. They study the problem, determine where and under what circumstances soldiers are being infected; why rates are high in one organization and low in another; what new forms of treatment or improved administrative methods may reduce the days lost from duty. They serve as advisers in these matters to their

superior officers, and assist in coordinating the efforts of military and civilian groups. They thus act in the military organization as a catalyst, making it possible more fully to utilize the available resources in combating these diseases.

I enlarge upon this feature of the Army's efforts because it seems to me no less important that a civilian program be built around medical specialists in this field. This has already been done in some states, but in too many states and cities in this country an effort has been made to do a big job with personnel inadequate both as regards quality and quantity. It is true that the Army has taken many well qualified men in this field from civilian life, but I can assure you that eventually the Army will repay this debt many times over.

A second noteworthy lesson to be drawn from Army experience is an understanding of the fundamental importance of the acceptance by the individual of some measure of personal responsibility in the control of these diseases. Related to this are questions concerning education and leadership.

Reference has already been made to the importance of education. The influence of that intangible quality called leadership is less well understood. In the Army it is a well established principle that the commanding officer is responsible for the health and welfare of his troops. Just as in civilian life, some diseases such as tetanus and small-pox can be prevented by purely medical measures. Whenever the individual must assume a measure of responsibility in his own protection, however, the rôle of the commanding officer cannot be overestimated, for in the Army this is related to discipline and morale, both of which stem from leadership. The same elements are present in civilian life. Civic leaders can do much to strengthen in the ordinary citizen the

desire to do the right thing, a pride in one's place in life, and a deep conviction concerning the dignity of the individual. I feel that our community leaders should play a more prominent part both as individuals and through groups in furthering measures that lead to good health. This must be done by leading, not by driving. I hope the day will come when the venereal diseases are universally regarded as diseases, not crimes. Punitive measures invariably promote concealment and operate directly against the best interest of the affected individual and the public health.

We are witnessing in many communities the successful control of disease through close integration of health, law enforcement, welfare, and other civic agencies. This is dynamic social action, which can be just as effective in peace as in war. Venereal disease control is essentially a local affair. Programs and funds may originate centrally, but in the final analysis we get only that amount

of control which the local community is willing to support. Blood test surveys on selectees have turned the light of day on venereal disease conditions in every community in the land. It is to be hoped that these data will be a stimulus to action at the earliest possible moment.

And, finally, I believe that this total mobilization for war has given us a new concept of the relation of health to welfare and efficiency. Time and again we see how the illness of one man may seriously cripple the team—a bomber crew, a tank crew, or a specially trained combat unit. The Army cannot afford the waste occasioned by venereal disease; our civilian economy now and after the war can no better afford it. We are developing, through this necessity for total effort, a new understanding of the individual's responsibility to stay well, of the community's responsibility to help him stay well, and of the physician as an integral and responsible part of community life and effort.

Fatal Staphylococcus Intoxication from Goat Milk

LYLE A. WEED, PH.D., M.D., AMOS C. MICHAEL, M.D., AND
ROLLA N. HARGER, PH.D.

*Departments of Bacteriology, Pathology, and Biochemistry and the Research
Division, Indiana University School of Medicine, Indianapolis, Ind.*

DURING the past decade there have been numerous reports of outbreaks of food poisoning due to Staphylococci. While such outbreaks are relatively common and frequently involve large numbers of people, fatalities are rare. In the timely summary entitled "Food Poisoning," by Dack² the statement is made that "Staphylococcus food poisoning in otherwise normal individuals is not fatal." While the incidence of fatalities is very small indeed, we believe there are records of apparently valid cases of fatal intoxication due to the ingestion of Staphylococci and their toxic products.

Dorling⁴ cites the case of an elderly individual dying 24 hours after eating the remainder of a can of soup opened 1 week previously. The patient had a whitlow on the left thumb at the time the can was opened. The soup had been kept at room temperature after opening the can. The onset of illness began with violent vomiting and diarrhea 3 hours after eating the soup. Post-mortem examination showed an inflammation of the gastric and intestinal mucosa. The gastrointestinal tract was filled with a thin ochre-colored fluid containing many Staphylococci similar to the organisms found inside the tin can. No Salmonella or similar pathogens could be isolated. The evidence in this case strongly suggests but does not prove that Staphy-

lococci were etiologically related to the illness.

Blackman¹ describes the case of a 12 year old colored girl who developed "vomiting, fever, headache, diarrhea, vertical nystagmus, fine tremor of the iris (hippus), spasticity and general collapse" 5 hours after eating a large Thanksgiving dinner. Death occurred 36 hours after the onset of illness. Post-mortem examination revealed "acute diffuse enteritis of ileum and jejunum, 'diphtheric membranes,' molds of ileum and jejunum, septicemia (*Staphylococcus albus*), thrombi in small vessels of intestine, liver, lung, kidney, vagina and lymph nodes, focal necroses in liver, spleen and bone marrow. Small hemorrhages in the stomach, colon, vagina, brain and meninges." There is some question in this case as to the fundamental nature of the etiology of the illness. The septicemia with numerous small thrombi and areas of focal necrosis diffusely distributed in the various organs suggest the condition was not due alone to the ingestion of many organisms and pre-formed toxins but more probably followed some unrecognized intra-abdominal staphylococcic infection.

Denys³ reported in 1894 one fatality in an outbreak involving several families, only two of which were interviewed for epidemiologic data. In this instance illness followed the eating of meat from

a cow which had suffered from puerperal sepsis. Symptoms included malaise, nausea, vomiting, diarrhea, abdominal pain, and prostration, with death following on the 3rd day. Bacteriological studies revealed many *Staphylococci* of both aureus and albus varieties, the latter predominating. Post-mortem examination in the one fatal case 3 days after death revealed much decomposition, moderate congestion of the peritoneum and intestine, with marked congestion of the trachea, larynx, and bronchi. The respiratory mucosa was red and infiltrated with "sanguinous suffusions."

Finnel⁵ cited in 1856 the case of a woman "who had died from poisoning by eating soup made from mutton, which had been cooked in the house for five or six days. The entire family, consisting of five persons, were poisoned; but all except the mother recovered. After eating the soup, the patient vomited and purged violently and died in a collapsed condition. The tongue throughout the attack was white." The details of the autopsy findings were not given. While the clinical findings were compatible with what is now recognized as *Staphylococcus* intoxication, there are not enough data to substantiate this interpretation.

Taylor¹¹ one hundred years ago recorded a case clinically typical of *Staphylococcus* intoxication with severe abdominal griping, vomiting, purging, and prostration, with the onset 3 hours after the meal. Since this was 40 years before Rosenbach demonstrated the relationship of *Staphylococci* to purulent lesions there are not sufficient data to prove they were the cause of the illness.

Epidemiologic data *—In the familial outbreak to be reported it would appear that two fatalities were due to the

drinking of raw, unrefrigerated milk drawn from a goat suffering from a unilateral mastitis.

On March 16, 1942, at 6:00 P.M. the goat was milked and nothing unusual was noted except that 6½ pints were obtained in place of the usual 8 pints. At 9:00 P.M. Ernest H., father of Ruth and Robert mentioned later, drank ½ pint of the milk. At 10:30 P.M. he became acutely ill with continuous vomiting and purging. At 11:00 P.M. he called the local physician and, after treatment by him, the vomiting and purging ceased. However, he continued to feel exhausted and complained of blurring of vision and of difficulty in focusing for the next few days.

On the morning of March 17, 1942, approximately 12 hours later, Mrs. E. H. used part of the milk (unrefrigerated) to make biscuits and gravy. This was served to 7 adults and 4 children (16, 8, 4, and 3 years of age). In addition Ruth and Robert (3 and 4 years old, respectively) each drank ¼ pint of the milk. Cream from the milk was served in the coffee which the adults drank. One and one-half hours later Ruth and Robert, suddenly while playing on the floor, and without warning, started vomiting. Robert had marked purging. There were no other complaints. At 11:00 A.M. the local physician was consulted and a prescription was obtained. The nature of this is unknown. Their condition continued to become worse and another physician was called to the home. At 6:00 P.M., which was the regular milking time, the goat was found dead. At 3:00 A.M. on March 18, 1942, Ruth died without convulsions. Robert died on the way to the hospital at 7:00 A.M., less than 24 hours after drinking the milk.

All the persons involved had been accustomed to drinking goat milk daily. The owner, mother of Ernest H., recalled that the animal had had a scratch on a teat two weeks previously.

* Taken mainly from the formal report of the district health officer.

This had been treated with a carbolic salve until March 15, 1942.

Chemical examination of the viscera of the goat and of these two children failed to detect any type of recognizable poisons which might have given rise to the gastrointestinal symptoms. Tests for fluorides, oxalates, arsenic, mercury, and other heavy metals were made.

Gross Pathological Findings—The significant gross findings in the goat were limited to the udder, one side of which was greatly swollen, red, and firm. The teat from this side had been removed post-mortem, presumably by the local veterinarian who had been consulted concerning the cause of death. An incision into the swollen side revealed marked congestion with numerous dilated lactiferous ducts containing a light reddish-brown fluid suggestive of bloody milk. No definite grossly visible abscesses could be found. The kidneys showed a small amount of cloudy swelling.

In the two fatal human cases the hearts, lungs, livers, spleens, and kidneys showed no significant demonstrable gross abnormalities.

Microscopic examination—(Goat) The sections of the udder showed numerous small abscesses containing Gram-positive cocci. In many areas the lumina of the lactiferous ductules contained purulent material composed of polymorphonuclear leucocytes and many Gram-positive cocci. The liver showed a moderate amount of fatty degeneration around the central veins but no abscesses or focal collections of leucocytes were found. Sections of the kidneys showed necrosis of the tubular epithelium in the cortical portion with cell outlines being completely obliterated. The glomerular loops contained a moderate number of polymorphonuclear leucocytes. There was a diffuse polymorphonuclear infiltration between the tubules in the cortical region. There was only an occasional sub-capsular

collection of leucocytes suggestive of beginning abscess formation.

(Children) The lungs showed a moderate amount of pulmonary edema with marked congestion of the alveolar vessels. In a few areas there appeared to be definite hemorrhages into the alveolae. The heart showed no demonstrable histopathology. There was a small amount of leucocytic infiltration—mainly polymorphonuclear—in the peri-portal areas of the liver with a moderate amount of fatty degeneration around the central veins. There was a slight increase in the nuclear content of the glomerular loops but no cortical necrosis as was seen in the goat kidneys. The cortical necrosis reported⁶⁻¹⁰ to be found in the kidneys of animals dying from the effects of *Staphylococcus* toxin was not present in the organs from the children.

Bacteriological examination—Smears made directly from the part of the udder showing the mastitis revealed myriads of Gram-positive cocci in clusters. The organisms appeared to be as numerous as found in a full grown fluid culture of *Staphylococcus aureus*. Plates streaked for isolated colonies revealed enormous numbers of colonies of hemolytic *Staphylococcus aureus*. No other type of organism was found by smear or culture.

By careful aspiration and by making several sections through the udder it was possible to obtain about 10 ml. of light reddish-brown fluid suggestive of blood tinged milk. This was used for animal inoculation. The material was centrifuged to obtain a supernatant fluid free of bacteria and leucocytes. Kittens injected with this material reacted with vomiting and diarrhea typical of the reactions described as being due to *Staphylococcus* toxin.*

* Monkeys were not available for testing the material although they would have been preferred. Fresh normal goat milk was likewise not available but the need for this was obviated as shown in the immunological data.

It would have been interesting, in the light of epidemiologic data, to have determined whether the enterotoxin in this supernatant fluid recovered from the udder was thermolabile or thermostabile. However, the amount of material available was not sufficient to test both its thermolability and its immunological properties. Since our main problem was to demonstrate whether such material from the udder might be related to the cases of intoxication, it was decided to use the material for the immunization experiment.

Immunological investigations—*Staphylococcus* toxin was prepared by growing the homologous strain in semi-solid agar under 20 per cent CO₂. The filtrate injected into kittens produced typical syndromes of vomiting and diarrhea. A series of 6 kittens was divided so that 3 were immunized over a period of 4 weeks by starting with small doses subcutaneously and gradually increasing the amount until 0.5 ml. amounts were given. The other 3 served as controls. At the end of this time they were tested for immunity to the toxic principle in the material taken from the udder. Three immunized kittens injected with the supernatant fluid of the material taken from the goat's udder did not develop any gastrointestinal symptoms. The 3 control kittens receiving aliquot portions of the supernatant developed typical reactions with vomiting and diarrhea in 1 to 2 hours.

DISCUSSION

The symptoms exhibited by the patients were typical of those which have been produced in human volunteers consuming known cultures of *Staphylococci*. The history of injury to the teat, the presence of an extensive acute suppurative mastitis due to *Staphylococcus aureus*, the reproduction of the symptoms in kittens, the immunization against this toxic material in the udder

by using a filtrate of a culture of the homologous strain of *Staphylococcus aureus*, all indicate that the symptoms in the patients were due to the toxin of this organism. It is generally accepted by most investigators of this subject that a separate entity called enterotoxin is responsible for the symptoms of diarrhea, nausea, vomiting, and abdominal pain. Dack, *et al.* have not been able to produce gastrointestinal symptoms with filtrates not containing enterotoxin. However, this does not mean that under proper circumstances similar symptoms may not, at least sometimes, be effected by the so-called "lethal factor" which is thought to be responsible for the death of rabbits when injected intravenously. Whether the symptoms of collapse and prostration are related in part or entirely to the vomiting and diarrhea or to the effect of the lethal toxin is not certainly known. The production of symptoms in Ernest H. 3 hours after drawing the milk suggests but does not prove that the toxin was present in the milk at the time it was drawn. The cortical necrosis in the kidneys of the goat were similar to the reactions previously described as resulting from injury by the toxin of *Staphylococcus aureus*. The pathological findings in the children under the conditions of examination did not reveal anything which could be logically considered the cause of death.

SUMMARY

Data are presented to indicate that 3 patients developed food intoxication by drinking milk of a goat suffering from an acute suppurative mastitis due to *Staphylococcus aureus*. Two of the patients (3 and 4 years old) died within 24 hours after each drank $\frac{1}{4}$ pint of the milk. Individuals consuming the cooked milk did not develop symptoms. The goat died within 24 hours after the milking related to the onset of symptoms. Material taken

from the udder post-mortem reproduced the symptoms in kittens. It was possible to immunize the kittens against this material by repeated injections of a filtrate from the homologous culture. The evidence suggests the possibility that if an enterotoxin was present it was thermolabile or that the lethal factor was responsible, at least in part, for the symptoms.

Rationing Milk in New York City

Ernest L. Stebbins, M.D., Commissioner of Health of New York City, recently declared himself as being opposed to reductions in the current fluid milk consumption in New York City which may be contemplated under recent orders of the War Food Administration. Commissioner Stebbins stated that, in his opinion, cuts in current milk consumption should be made only as a last resort, and that no reduction should be made in the milk supply of schools and other institutions nor in the amount of milk sold at stores or through retail deliveries for home use.

If cuts in fluid milk consumption prove absolutely necessary, it was recommended that they should be made first through further reduction in uses for whipped cream, table cream, candy and frozen desserts. If still further reductions are absolutely imperative, a possible curtailment would be to take out from the fluid milk served to restaurants and soda fountains, even though this may affect the nutrition of some industrial workers.

Dr. Stebbins gave the following broad classifications of milk uses in New York City in order of relative importance:

	Number of Persons	Quarts of Fluid Milk Daily
1. Children in institutions (under 15 yrs. of age)	30,000	30,000
2. Penny milk and free lunch milk	150,000
3. Balance of child population (under 15 yrs.)	1,413,000	1,060,000
4. Adults in institutions	50,000	30,000
5. Other institutional use (cooking, staff use, etc.)	15,000
6. Balance of adult population	6,131,500	1,915,000
Total	7,624,500	3,200,000

Classification of Types of Milk Delivery Services in order of relative importance:

	Estimated Quarts Daily
1. To institutions	75,000
2. To schools (penny milk and free lunches)	150,000
3. To retail stores and direct to houses	2,545,000
4. To restaurants and soda fountains	430,000
Total	3,200,000

The Sanitary Privy and Its Relation to Public Health

E. S. TISDALE AND C. H. ATKINS

Sanitary Engineer, and Assistant Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

IN the early part of the 20th century it was discovered that the prevention or control of typhoid fever, diarrhea, dysentery, hookworm, and other enteric diseases was dependent upon the sanitary disposal of human excreta. The facilities developed to break the chain of transmission of these diseases between the patient or carrier and the susceptible host were sewerage systems, septic tanks, and sanitary privies. In areas where sewers or septic tanks were impracticable, sanitary privies came to be recognized as essential facilities in the protection of the public health.

During the period 1910 to 1913, state boards of health became active in the control of hookworm. These agencies were assisted by the U. S. Public Health Service and volunteer health organizations. The Rockefeller Sanitary Commission, which was established in 1909 to combat hookworm disease, sponsored hookworm control programs in the South. Sanitation and infestation surveys made in 11 southern states confirmed the presence of hookworm disease in every one of the 700 counties investigated, and indicated that soil pollution was the chief factor in the spread of this disease. Programs for the control of hookworm disease followed these surveys. These programs involved free examination and treatment of patients, installation of sanitary privies, and promotion of their use. Emphasis was placed on the use

of sanitary privies as a means of protection against typhoid fever and dysentery as well as hookworm disease. Concurrently the Public Health Service carried on rural sanitation demonstration projects.

In 1914-1917, Dr. L. L. Lumsden of the Public Health Service and his coworkers made house-to-house sanitation surveys in 18 representative counties in 16 states, the work being financed by a federal appropriation. These rural sanitation enthusiasts convinced local authorities in West Virginia, Indiana, Washington, and other selected states that sanitary privies were a good investment. As a result, local funds were provided for employment of public health personnel whose major duty it was to see that throughout the community human excreta were disposed of in a sanitary manner. This rural sanitation activity provided the groundwork for organization of the early full-time county health units in the United States. Thus, the lowly privy may be considered a primary factor in the development of a movement of tremendous health significance to the nation as a whole.

The public health personnel with experience in the conduct of such rural sanitation projects served as the nucleus for the extra-cantonment sanitation program during World War I. There were at that time few well organized state and local health departments;

hence the Public Health Service assigned medical and sanitation personnel to the extra-cantonment zones. It was one of their duties to organize and direct local efforts toward obtaining safe water, safe milk, and, above all, sanitary disposal of human excreta. The construction of several thousand sanitary privies was a major part of this program. In addition to protecting the health of the armed forces and civilians in the war areas, perhaps the most significant result of this close coöperation between the Public Health Service and state health departments was the further stimulation of the development of full-time local health services.

During the interval between the first World War and the economic depression in the early 1930's, state health departments were strengthened, additional local health services were organized, and sanitary privy construction was carried on as an important function of these agencies. Plans, specifications, and regulations governing the construction and maintenance of septic tanks and sanitary privies were developed. Personnel were assigned to conduct sanitation surveys and educational campaigns, enforce the sanitary laws where necessary, and supervise the construction of septic tanks and sanitary privies. Thus the foundation was laid for the future nation-wide privy construction program undertaken to protect the public health and give employment to relief labor.

In December, 1933, the Civil Works Administration was established to relieve unemployment. The U. S. Public Health Service recognized in this program an opportunity to improve rural sanitation work, and secured an allotment of CWA funds for the construction of sanitary privies. This was the beginning of the "millennium" for the men who had spent years in promoting construction of sanitary privies through education, exhortation, persuasion, and

enforcement of sanitary laws. The CWA furnished the necessary labor, and property owners provided the materials. Technical supervision of the community sanitation projects was provided by the Public Health Service through personnel assigned to the state health departments. This program, although of short duration, demonstrated that the construction of sanitary privies was a desirable work-relief project in the field of public health. Similar community sanitation projects were continued under the Federal Emergency Relief Administration and the Work Projects Administration.

Observation of privies constructed prior to the inception of the federal work-relief program revealed that practically all pit privies had wood floors and risers which rapidly decayed and were difficult to keep clean. Recognizing the need for a more permanent type of construction, the Public Health Service developed a concrete slab and riser type of privy. A majority of state health departments either adopted this design or developed a similar type of concrete slab and riser earth pit privy. After observing advantages afforded by concrete slabs and risers a number of states made this type of construction mandatory. About 90 per cent of the privies constructed during the fiscal year 1939 under the Community Sanitation Program were of this type.

During the period from December, 1933, through June, 1942, 2,911,323 sanitary privies were constructed in 38 states and in Puerto Rico through the coöperative effort of the CWA, FERA, WPA, state health departments, and the U. S. Public Health Service.

To appreciate the magnitude of the Community Sanitation Program conducted by the work-relief agencies during the last 10 years it is only necessary to indicate the materials required and the funds involved in the construction of nearly three million privies. The

amounts of materials used were roughly as follows:

Lumber	1,000,000,000 bd. ft.
Cement	6,000,000 bags
Sand and gravel	1,000,000 cu. yds.
Reinforcing steel	12,000 tons
Roofing	110,000,000 sq. ft.
Nails	24,000,000 lbs.
Hinges	6,000,000 pairs

It is assumed that the average costs of material and labor were \$15 and \$20 respectively, and that supervisory costs were 5 per cent. On this basis it is estimated that the sum of \$110,000,000 was expended for the construction of sanitary privies under the various work-relief programs. Of this amount, approximately \$45,000,000 was provided for materials by the property owners concerned.

What benefits, in addition to affording employment to an estimated average force of about 15,000 men, accrued from this sizeable expenditure? Concurrently with the Community Sanitation Program remarkable progress was made in the construction of municipal water and sewerage systems, in milk sanitation, and in other aspects of environmental sanitation through the federal grants-in-aid system designed to further public health activities. Therefore, it is impossible to claim for any one activity a predominant rôle in the reduction of intestinal diseases. Nevertheless, in states such as West Virginia, Tennessee, North Carolina, and Mississippi, where the greatest number of sanitary privies were constructed, there were significant reductions in the incidence of typhoid fever, dysentery, and other intestinal diseases. In view of the large number of persons employed on the projects and the fact that in "selling" 3,000,000 privies it was necessary to explain to at least 15,000,000 persons the reasons why sanitary excreta disposal was essential to protect the public health, it cannot be doubted that the Community Sanitation Pro-

gram contributed significantly to public understanding of the importance of this phase of environmental sanitation.

Further impetus to the sanitation of rural areas was provided by the Farm Security Administration, whose public health program was organized and directed by officers of the Public Health Service. The FSA realized that farmers ill with typhoid fever, dysentery, or malaria could not maintain adequate farm production or repay crop loans. Therefore, a farm sanitation program was organized, the basic elements of which involved provision of sanitary privies, safe domestic water systems, and screening of homes. Under this program approximately 92,000 sanitary privies were installed, 45,000 domestic water supplies were protected, and 58,000 homes were screened. Work was carried on in all 48 states, and, since the FSA assisted farmers whose financial resources were extremely meager, the work was done on properties where it was most needed and where sanitation paid the greatest dividends. Many of the farms on which improvements were made had previously lacked privies of any kind. State and local health departments participated in the FSA program, and their policies were adhered to and respected by the federal agency.

During the present emergency state and local health agencies are in a much better position with regard to extracantonment sanitation than they were during the first World War. Sanitation personnel have been recruited and trained by the Public Health Service and have been assigned to the states to assist in maintaining and improving environmental sanitation in war areas.

Although outstanding progress has been made in the construction of sanitary privies, much remains to be done in providing sanitary excreta disposal facilities where water carriage sewerage systems are impracticable. Reconnaissance

sance surveys made by the Public Health Service indicate that about 165,000 additional sanitary privies are needed in the war areas. Thus it is apparent that privy construction is an important part of the present extra-cantonment sanitation program. The 1940 census revealed that there are 14,778,360 rural homes in the United States. Of these, 9,631,762 are served by outside toilets and 907,923 have no toilet facilities. The 3,000,000 privies constructed under the work-relief programs, and 50 per cent of the remainder of the privies serving rural homes, or a total of about 6,300,000, now are assumed to be reasonably satisfactory. On this basis it is conservatively estimated that more than 4,000,000 additional sanitary privies are needed in this country. The construction of these basic sanitary facilities should be included in any post-war public works program which may be instituted to relieve unemployment. In any event, after the present emergency, state and local health departments should assign sufficient personnel to rural sanitation activities to conduct educational campaigns, to secure the enactment and enforcement of adequate sanitation ordinances, and to provide sanitary excreta disposal facilities for about 16,000,000 people now without these fundamental necessities.

The sanitary privy has a definite relationship to public health and in this

connection, the following points are significant:

1. In areas where water carriage sewerage systems are impracticable the privy is the facility relied upon to break the transmission chain of intestinal diseases.

2. Privy construction programs, originally undertaken in the hookworm and typhoid fever regions in the South thirty years ago, contributed substantially to the early development of full-time local health services. At present more than 1,800 counties in the United States have such services.

3. The 3,000,000 sanitary privies constructed under the various work-relief programs have had an important effect in reducing the incidence of intestinal diseases.

4. The close association of U. S. Public Health Service officials with state health departments in rural sanitation campaigns over a period of 30 years has been instrumental in developing the *esprit de corps* which now enables local, state, and federal health services to cope successfully with problems of sanitation, malaria, venereal disease, and industrial hygiene in critical war areas in America today.

5. The fundamental principles of federal-state coöperation, successfully demonstrated in the rural sanitation programs, are now being applied throughout the field of public health. In addition, coöperative plans for public health work among selected population groups have been developed by the Public Health Service with other federal agencies. The Farm Security Administration's health and sanitation program is an example of federal coöperative health work.

6. Approximately 4,000,000 additional sanitary privies are needed to serve about 16,000,000 persons now without sanitary excreta disposal facilities, who for the most part reside in areas having the highest incidence of typhoid fever, dysentery, and hookworm.

Further Studies on One Type of Paracolon Organism^{*}

C. A. STUART, PH.D., AND ROBERT RUSTIGIAN, PH.D.

Biological Laboratory, Brown University, Providence, R. I.

FOR many years continental bacteriologists, including the English, have considered the paracolon organisms as a group intermediate between the coliform and *Salmonella* bacteria. Topley and Wilson (1938) say of the paracolon group, "Certain of these species are definitely pathogenic for man. Others are under suspicion in this respect. Others again are almost certainly non-pathogenic." Stuart *et al.* (1943), after studying 465 paracolon cultures, isolated for the most part from gastroenteritis patients over a period of 4 years, came to identical conclusions. These investigators found that the paracolon group, like the coliform bacteria, could be divided into three sections: paracolon *Aerobacter*, paracolon intermediates, and paracolon *Escherichia* according to their IMViC reactions. Each section was again divided into a number of biochemical types according to their carbohydrate reactions.

Of all cultures studied biochemical type 32011,[†] a paracolon *Aerobacter*, offered the best evidence for pathogenicity. Thirty-one of the 35 strains investigated were isolated from gastro-

enteritis patients and 4 from food handlers in one or another institution in which the strain had been isolated during so-called food poisoning epidemics. In the course of 5 weeks in the Rhode Island Hospital 4 patients listed as "typhoid suspects" yielded almost pure cultures of biochemical type 32011 from the feces and one a pure culture from the blood.

At the April, 1942, meeting of the New England Health Institute the senior author read a paper on the paracolon group, emphasizing the probable pathogenicity of biochemical type 32011 (hereinafter called bio-type). Within one year 114 strains of this organism were received from a number of New England laboratories.

Bio-type 32011 ferments glucose, maltose, mannitol, and frequently salicin, in 24 hours. Strong acid reactions (brom cresol purple indicator) and 20 to 30 per cent gas are produced in glucose and, when positive, in salicin. In maltose, however, a moderate acid reaction with or without a bubble of gas and in mannitol a moderate to strong acid reaction and a bubble to 10 per cent gas are produced in 18 to 24 hours. Lactose and sucrose are fermented slowly or not at all; some strains ferment one or another or both of these carbohydrates in about 6 days and other strains only after 3 to 4 weeks. Some strains ferment salicin rapidly, others slowly, and some are negative. Growth, usually of the beaded type, occurs on citrate agar in 5 to 30 days

^{*} Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

[†] Biochemical type 32011 was previously described by Stuart, *et al.*, 1943. After their paper was published it was found that cultures with the biochemical reactions of 32011 could be divided into several different serological types as shown in Table 1. Biochemical type 32011—serological type 32611, for example, means that cultures of serological type 32611 have all the biochemical reactions of 32011 but differ antigenically from 32011.

and the Voges-Proskauer reaction is positive though usually weak with freshly isolated strains. A great majority of strains are motile. The only nonmotile paracolon *Aerobacter* encountered among 343 cultures studied in this laboratory to date were not only bio-type 32011 but also sero-type 32611 (Table 1). (One previously reported nonmotile paracolon *Aerobacter*, bio-type 32821, Stuart, *et al.* (1943), was found to be bio-type 32011 and sero-type 32611.) Because of the relatively slow action on maltose and mannitol in 18 to 24 hours bio-type 32011 almost always can be distinguished easily from other paracolon types of any section.

Table 1 shows that 58 strains were sero-type 32011 while 21, 15, 9, 9, 7, 6, and 2 were sero-type 26311, 44311, 32611, 63511, 56211, 70811, and 64811, respectively. All eight sero-types possessed interlocking somatic, and in some instances flagellar, antigens. Three sero-types had minor, unlabeled somatic antigens in common with *Salmonella choleraesuis* and *Salmonella rubislaw*.

Twenty-two of the 149 strains did not belong to any of the eight sero-types. These strains, however, possessed antigens in common with one or another of the eight sero-types. Fourteen of them agglutinated to high titers with one or another of the eight antisera (five to

TABLE 1
Serological Types of Biochemical Type 32011

	Sero-types								
Number of strains	32011	26311	44311	63511	32611 °	56211	70811	68411	Unknown
	58	21	15	9	9	7	6	2	22

° = All strains nonmotile

Of the 35 strains isolated from gastroenteritis patients as mentioned above, 32 were antigenically identical or closely related. As new cultures were obtained, however, it was evident that bio-type 32011 was serologically heterogeneous. Biochemical reactions were of no value in establishing different sero-types in this bio-type. Several strains of bio-type 32011 agglutinated in serum dilutions of 160 and a number of others in dilutions as high as 1280 of 32011 antiserum, but failed to reduce the homologous titer when used to adsorb the antiserum. Antisera were prepared from one culture agglutinating to 160 and from one agglutinating to 1280. Thus two new sero-types were established. By agglutination and adsorption tests with the three antisera, and the preparation of additional antisera, eight sero-types were identified in bio-type 32011.

Of a total of 149 strains of bio-type 32011, 127 (85.2 per cent) fell into one or another of eight sero-types.

the homologous titer) but in no instance was the homologous titer of any antiserum reduced upon adsorption.

Unfortunately, adequate information could not be obtained about the source of all of the 114 new strains. Eighty-six were from gastroenteritis patients (81 from feces and 5 from blood), 7 from food handlers, 2 from apparently normal contacts of patients, 1 from milk, 1 from pastry, and 17 from fecal specimens of unknown history. Eleven strains of sero-type 32011 and 3 of sero-type 26311 were isolated from patients listed as "typhoid suspects" which, with the 4 previously cited, make a total of 18 strains of bio-type 32011 isolated from patients suspected of having typhoid fever.

DISCUSSION

Adequate methods for the accurate determination of the toxicity and pathogenicity or aggressiveness of the *Enterobacteriaceae* are lacking. Despite this the pathogenicity for man of certain

Salmonella and *Shigella* species is well established if for no other reason than by the large mass of *in vivo* evidence. The pathogenicity of other species in these genera has been questioned. Because, for example, *Shigella alkalescens* (Andrews 1918) has been isolated occasionally from normal individuals, it usually is considered nonpathogenic. Both Neter (1942) and Weil (1943), in their reviews on *Shigella* agree that sufficient evidence has accumulated to show that under certain conditions this species can cause gastroenteritis and other infectious processes.

In view of the foregoing it seems that the pathogenicity of paracolon bacteria will not be established easily. Some bacteriologists will concede that a paracolon culture and a *Salmonella* type with identical somatic antigens will possess the same endotoxins, but the two cultures may have entirely different aggressive properties. For paracolon cultures such as bio-type 32011 having no major antigens in common with *Salmonella* the evidence for pathogenicity must rest on the sources and frequency of isolations.

Where epidemics have occurred in institutions a careful search has nearly always located a food handler carrying the organism. In specimens from food handlers plated on eosin-methylene-blue agar bio-type 32011 comprised only a small fraction of the flora while specimens from patients after onset of symptoms usually gave almost pure cultures of the organism. The loss of symptoms coincided with the disappearance of almost pure cultures from the feces.

The close association of the organism with gastroenteritis is shown by the following example: In a neighboring hospital 28 cases of mild to acute gastroenteritis occurred among patients and staff over a period of several hours on one day. A milk supply was the

only common factor other than water. The 48 hour milk plates which had been counted the day before the epidemic had not been discarded; and isolations were made from these plates. Because of the loss of personnel due to the war only 2 fecal specimens from patients reached the laboratory. Several cases were reported in the city, emanating from a restaurant using the same milk supply as the hospital. A fecal specimen from one patient and cream filling from pastry were sent to the laboratory. From the cases in the hospital and city, the milk plates of the hospital, and from the cream pastry organisms of bio- and sero-type 32011 were isolated. Two laboratory infections have been caused by this organism, one in a student frequently working with bio-type 32011 and the other in a technician washing glassware, who had an acute gastroenteritis attack 4 days after a number of broth tubes of this organism had been placed by mistake in a basket marked "nonpathogenic."

Each year for the past 7 years fecal specimens from about 50 normal students have been examined. A few paracolon cultures have been isolated from these specimens but never bio-type 32011.

It hardly can be coincidence that 116 bio-type 32011 strains were isolated from known gastroenteritis patients and 11 from food handlers involved in epidemics, or that the same organism was isolated from milk or milk products involved in an epidemic or that 18 strains were isolated from typhoid suspects.

SUMMARY—Strong evidence has been found of the pathogenicity for man of one type of paracolon *Aerobacter*.

Neutralization of SK Murine Poliomyelitis Virus and of Theiler's Virus of Mouse Encephalomyelitis by Human Sera^{*}

Columbia University, New York, N. Y.*

IT is generally accepted that a majority of normal human sera contain substances which are capable of inactivating various strains of monkey poliomyelitis virus. It is also commonly agreed that the frequency with which such sera neutralize the virus tends to be appreciably higher than that observed with sera obtained from poliomyelitis convalescents. The nature of this phenomenon is by no means clearly understood. Nevertheless, the neutralization test has often been used in surveys as an epidemiological tool to indicate the distribution of latent immunity, and hence presumable exposure to the disease, in human populations.

The possible occurrence in human sera, both normal and convalescent, of similar neutralizing substances against rodent poliomyelitis virus was first explored with the murine Lansing strain. The work of Harford and Bronfenbrenner,¹ Kramer,² and Toomey and Takacs,³ reflecting extensive experience with mice or cotton rat experiments, suggested that virucidal antibodies may develop, though not regularly, during

convalescence from an attack of poliomyelitis. Somewhat analogous observations were recorded by Plotz, Reagan, and Hamilton,⁴ who employed virus of the Lansing strain adapted to the Syrian hamster. Different conclusions, however, were reached by other authors, including Armstrong and his coworkers.^{5, 6} Thus, while from 65 to 75 per cent of all human sera examined were capable of neutralizing the Lansing murine virus in intracerebral tests in albino mice, it appeared that the determining factor for the production of such antibodies was age rather than the individual's experience with clinically recognized poliomyelitis. A similar opinion was expressed by Hammon and Izumi⁷ as well as by Turner and Young,⁸ the former authors also stressing the difficulties which surround the interpretation of results obtained with a not too well adapted virus, such as Armstrong's mouse strain.

There seems fair agreement, then, that neutralizing substances against the Lansing murine virus are widely distributed among human beings, but that the presence of these substances is no reliable measure of known previous contact with the actual disease. In other words, the picture is very much the same as had previously been assembled

^{*} Aided by grants from the Warner Institute for Therapeutic Research, the Philip Hanson Hiss, Jr. Memorial Fund, and gifts from anonymous donors.

from the prolonged study of neutralization tests with human sera, both normal and convalescent, against simian strains of poliomyelitis virus in rhesus monkeys. It may therefore be said that the neutralization test, carried out with rodent poliomyelitis virus, fails to offer any constructive aid in the diagnostic problems of the disease. By further implication it becomes apparent that tests of this kind are of little value in determining the etiological position within the poliomyelitis group of a given neurotropic murine virus.

Little information has yet been gathered on neutralization of the murine strain of SK poliomyelitis virus by human sera, normal or convalescent. In a previous communication⁹ it had been reported that normal human serum (3 samples) failed to inactivate SK murine virus, whereas convalescent serum (1 pool) proved capable of bringing about partial neutralization of small doses of virus (2 m.f.d.). These tests were carried out in mice by the intraperitoneal method.

Comparable data referring to neutralization of Theiler's virus of mouse encephalomyelitis by human sera are very scanty. Following Olitsky's¹⁰ original report that pooled convalescent serum possessed no neutralizing power against Theiler's virus, Young and Cumberland¹¹ recently stated again their inability to demonstrate any neutralizing capacity in either normal human sera or in sera from poliomyelitis convalescents. All of the above tests were carried out in mice by employing the intracerebral route for the injection of virus-serum mixtures.

In view of the limited character of these earlier observations, it seemed of interest to examine a larger number of human sera, both normal and convalescent, for their ability to neutralize SK murine poliomyelitis virus. Since the murine SK strain possesses a fairly high and uniform potency on intra-

peritoneal injection, the latter route was chosen for injecting virus-serum mixtures. At the same time it was thought advisable to review the possibilities of obtaining neutralization of Theiler's virus by human serum with the intraperitoneal method of testing. The reasons which prompted this reinvestigation were: (1) that it had been found difficult—if not impossible—to secure satisfactory evidence of neutralization of Theiler's virus, in intracerebral tests, by specific rabbit hyperimmune serum, whereas the same serum proved extremely potent in intraperitoneal tests; and (2) that by utilizing the intraperitoneal route for the injection of mixtures of virus and hyperimmune sera it had been possible to disclose the existence of a broad serological relationship between the various viruses belonging to the poliomyelitis group, i.e., Theiler's virus, SK murine poliomyelitis virus, MM murine poliomyelitis virus, and monkey poliomyelitis virus.^{12, 13}

The results obtained in the investigation of the problems referred to above are presented in two sections of this paper.

EXPERIMENTAL

1. NEUTRALIZATION TESTS WITH SK MURINE POLIOMYELITIS VIRUS AND SERA FROM NORMAL INDIVIDUALS OR FROM POLIOMYELITIS CONVALESCENTS

Material—SK murine virus was harvested from the brains of paralyzed mice, representing the strain in its 219th and subsequent mouse passages. The sera comprised samples from both normal individuals and poliomyelitis cases and contacts. The normal sera were obtained from Beth Israel Hospital, New York, N. Y., or from the State Laboratory, Albany, N. Y. They had been inactivated for $\frac{1}{2}$ hour at 56° C. prior to being used in routine Wassermann tests. The New York

TABLE 1

Neutralization of SK Murine Poliomyelitis Virus by Human Sera from Normal Individuals and Poliomyelitis Convalescents or Contacts

Type of Serum	Number of Sera	Positive			Negative
		20 m.f.d.	10 m.f.d.	1 m.f.d.	
Normal urban population	102	3	8	10	81
Normal rural population	30	0	0	1	29
Poliomyelitis cases (early)	10	0	0	2	8
Poliomyelitis cases (late)	9	0	0	1	8
Poliomyelitis contacts	16	0	0	2	14
Total	167	3	8	16	140

City sera came preponderantly from adult urban individuals, the Albany sera from adult persons with rural residence. The sera from poliomyelitis patients, or from healthy family members who had been in contact with such cases, had been collected by Dr. Gilbert Dalldorf during an outbreak of the disease in Westchester County in the fall of 1941; they included sera from both children and adults. Some patients' sera represented repeat samples taken during the early stages of the attack and again later in convalescence.

Methods—Undiluted sera were mixed with variable virus dilutions in a ratio of 1:10, yielding final dilutions of virus which were 10 times higher than the original test dilutions employed. Serum-virus mixtures were incubated for 1½ hours at 37° C. and then injected intraperitoneally, in a volume of 0.1 ml., into each of 3 young Swiss albino mice. Each test was controlled by including similarly incubated mixtures which contained the same dose of virus together with normal guinea pig serum. Normal guinea pig serum rather than saline was used since virus, in high dilutions, tends to deteriorate rapidly in salt solution, whereas serum affords some protection against this deterioration. All the sera were run against two initial virus dilutions, i.e., 1:10,000 and 1:100,000;

one-half of the sera were also tested against initial virus dilutions of 1:5,000 and 1:500,000, respectively.

Absence or presence of neutralization was appraised on the basis of a simple system which allowed due consideration for any periodic fluctuations that might occur in the level of potency of the virus. This pattern was as follows:

Control Serum	Test Serum	Result
3/3	3/3	Negative
3/3	2/3	"
3/3	1/3 or 0/3	Positive
2/3	2/3	Negative
2/3	1/3	"
2/3	0/3	Positive
1/3	1/3	Negative
1/3	0/3	"

Numerator = number of mice paralyzed;
denominator = number of mice injected.

Results—The ceiling of infectivity of the virus, under the conditions of the test, was in the neighborhood of 1:1,000,000 *final* virus dilution. In other words, up to and including this dilution, practically all of the control mice injected with mixtures of virus and normal guinea pig serum became paralyzed, whereas paralysis occurred irregularly with the next higher dilution. For the purpose of this test, therefore, a level of 1:1,000,000 *final* virus dilution was considered as repre-

senting one minimum fatal dose.* Table 1 will show the frequency and the degrees of neutralization obtained with the various human sera.

These figures demonstrate that the great majority of the sera examined possessed no neutralizing power whatsoever against SK murine poliomyelitis virus. Thus, of a total of 167 sera tested, 140 were completely negative while 27 were listed as positive. However, inasmuch as virus inactivation of only 1 m.f.d. represents a borderline phenomenon, with little or doubtful significance, there remain only 11 clearly neutralizing sera which were capable of inactivating 10 m.f.d., or in excess of 10 m.f.d., of virus. The latter sera were all encountered in a series of 102 specimens obtained from normal urban residents. The incidence of positive sera was therefore approximately 10 per cent for this particular series against about 6 per cent for the entire group. By contrast, the other two series, i.e., samples from normal rural residents or from poliomyelitis cases and contacts, were made up of sera which were essentially negative.

2. NEUTRALIZATION TESTS WITH THEILER'S VIRUS OF MOUSE ENCEPHALOMYELITIS AND SERA FROM NORMAL INDIVIDUALS

Material—The virus was the GDVII strain, originally received from Dr. Max Theiler of the Rockefeller Foundation. The strain has since been maintained in this laboratory by continuous transfer from mouse to mouse.¹⁴ The virus was obtained from the brains of paralyzed mice, representing the strain in its 120th and subsequent passages. The sera were samples which had been submitted for routine Wassermann tests to the diagnostic services of either Beth

Israel Hospital or Presbyterian Hospital. All sera had been inactivated for $\frac{1}{2}$ hour at 56° C. The donors were presumably all residents of New York City.

Methods—Neutralization tests were performed in young Swiss albino mice, using either the intracerebral or intraperitoneal route for injection of the virus-serum mixtures. Thirty sera were examined by the intracerebral method and another 100 sera by the intraperitoneal method. For the intracerebral test the undiluted sera were mixed with virus dilutions varying from 1:1,000 to 1:1,000,000 in a ratio of 1:10; the mixtures were held for $1\frac{1}{2}$ hours at 37° C. and were then injected intracerebrally into each of 3 mice in a volume of 0.03 ml. For the intraperitoneal test, serum-virus mixtures were prepared by combining undiluted serum with a standard virus dilution of 1:10 in equal proportions; after incubation for $1\frac{1}{2}$ hours, the mixtures, in a volume of 0.4 ml., were injected intraperitoneally into each of 3 or 5 mice. The level of 10^{-1} virus dilution was chosen because, although paralysis occurred occasionally with smaller doses of virus, it represented the only dilution which paralyzed mice fairly regularly upon intraperitoneal injection.* Adequate controls consisting of virus in combination with either normal adult mouse serum, normal guinea pig serum, or normal rabbit serum accompanied both series of tests.

Results—Of a total of 30 normal human sera examined, not a single specimen was capable of inactivating Theiler's virus in intracerebral tests. Inasmuch as the amounts of virus used extended well into the range of border-

* The intraperitoneal infectivity of the virus, at the indicated level, was well maintained over serial passages throughout the year, except during the summer months. Attempts to run additional tests between June and September had to be abandoned, in two successive years, because of loss of potency or marked irregularities in the intraperitoneal titer of the virus.

* Current passages of SK murine virus (300th and subsequent passages) titrate about 10 times higher intraperitoneally.

line infectivity, as determined by the response in control mice, the lack of neutralization cannot be attributed to excessive dosage of virus. Different results, however, were obtained in intraperitoneal tests, as will be gathered from Table 2. If neutralization be con-

DISCUSSION

The results obtained in this study reveal that in the neighborhood of 6 per cent of all human sera examined, normal or convalescent, were capable of inactivating SK murine poliomyelitis virus. This percentage of neutralization

TABLE 2
Neutralization of Theiler's Virus of Mouse Encephalomyelitis by Normal Human Sera (Intraperitoneal Test)

Series	Sera	Incidence of Paralysis as Observed with Individual Sera

* Numerator = number of mice paralyzed; denominator = number of mice injected.

sidered positive in case none of the mice receiving a particular serum-virus mixture developed paralysis, whereas between 60 and 100 per cent of the control mice receiving normal cotton rat, rabbit, or guinea pig serum-virus mixtures became paralyzed, it will be found that of a total of 100 normal human sera examined 9 neutralized Theiler's virus. An additional 4 human sera may have possessed slight virucidal power since more than three-fourths of the injected mice remained free from paralysis; but in view of the fact that the mortality among control mice varied from test to test and rarely reached the 100 per cent level, it would seem safer to ignore the latter reactions at present. The neutralization observed with the two normal adult mouse sera is, of course, characteristic of this virus and in line with previously established facts.

is substantially lower than has been recorded for the Lansing strain. It is impossible to say at present whether this difference is due to technical reasons—greater uniformity in virus activity and more rigid interpretation of the results—or to a more limited dissemination of the SK strain as an immunizing agent among human populations. While the actual percentage of positive sera was very low indeed, nevertheless the data follow a trend which has been firmly established by previous experience with simian strains of poliomyelitis virus; thus, the peak frequency of neutralization, i.e., about 10 per cent, occurred in a group of normal adult urban sera. Inasmuch as none of the sera examined here had been tested for virucidal power in monkeys, no basis exists which would allow a point for point comparison. It

may be of interest, however, in this connection to mention that one of the children included in the group of healthy contacts apparently carried active poliomyelitis virus as shown by the development of paralysis in one monkey following intracerebral injection with Duponol-treated feces collected from this individual. In spite of such proven carriage, no virucidal substances could be detected in the serum of this child.

Our observations relating to Theiler's virus harmonize with earlier reports to the extent that they confirm the inability of demonstrating the presence of any virucidal antibodies in normal human sera by intracerebral tests in mice. They differ significantly, however, from the current belief that such sera fail altogether to neutralize Theiler's virus, since definite neutralization occurred in about 9 per cent of all sera tested, provided the tests were carried out with the intraperitoneal method. The above figure represents the average from four individual series of tests. These series differed among themselves not only in technic (in series I, 3 mice were employed for each sample of serum as against 5 mice in series II-IV), but they were also subject to considerable variations (60-100 per cent) in the infectivity of the virus for controls. Had it been possible to standardize the test by using throughout virus of maximal potency with a uniform technic, an appreciably lower over-all percentage of neutralization would probably have been recorded. The data collected here, therefore, make no claim to be statistically valid. They seem to indicate, however, that a small fraction of normal human sera carry substances capable of inactivating Theiler's virus. The selectivity of this neutralization contrasts sharply with the regularity with which normal adult mouse sera neutralize the same virus.

Two alternate hypotheses suggest

themselves for the interpretation of the above data. One, that Theiler's virus may, on occasion, operate as a specific immunizing agent among human populations as it does so regularly among mice; the other, that the virucidal action of normal human serum is due to a nonspecific principle which acts in a similar manner on both monkey and rodent strains of poliomyelitis virus. Whatever the correct explanation, the findings reported here furnish additional evidence of the intrinsic relationship that exists between the various simian and rodent viruses that belong to the poliomyelitis group.

SUMMARY AND CONCLUSIONS

1. Among a total of 167 human sera, normal or convalescent, which were examined for their ability to neutralize SK murine poliomyelitis virus in intraperitoneal tests in albino mice, 11 were found to neutralize this virus. These neutralizing sera occurred all in a group of 102 normal sera obtained from urban residents.

2. A total of 30 normal human sera were examined for their ability to neutralize Theiler's virus of mouse encephalomyelitis in intracerebral tests in albino mice. None showed any neutralizing power.

3. Among a total of 100 normal human sera obtained from urban residents, which were examined for their ability to neutralize Theiler's virus in intraperitoneal tests in albino mice, 9 were found to neutralize this virus.

4. The significance of the above findings is discussed in the light of the available data on the neutralization of simian and murine strains of poliomyelitis virus by human sera.

Wartime Health Education in Secondary Schools

RUTH E. GROUT, PH.D., F.A.P.H.A.

*Associate Professor, Preventive Medicine and Public Health, and Education,
University of Minnesota, Minneapolis, Minn.*

SECONDARY schools today have become the nation's most vital centers in the preparation of youth for wartime services. It is generally agreed that a basic part of this preparation should be to help youth to become physically and mentally fit for the rôles they will play as members of the armed forces, or as workers in industry, agriculture, and in community service. For those high school youth who already are engaged in wartime services the need is immediate and urgent. For youth in training for some future service, health preparation should become an essential part of the training.

In recognition of the need for increased attention to fitness of youth, the U. S. Office of Education, in the fall of 1942, called together two committees to consider the problems involved and to outline appropriate suggestions for action. These committees consisted of leaders from the fields of health education and physical education, and representatives from the Army, the Navy, the Public Health Service, the Children's Bureau, and the Office of Education. Out of the deliberations of these committees, two manuals were prepared. The first, *Physical Fitness through Physical Education for the Victory Corps*,¹ was published early in 1943; the second, *Physical Fitness through Health Education for the Victory Corps*,² has recently come off the press.

The first manual, as its name implies,

outlines physical education activities for high school boys and girls, especially adapted to wartime requirements. The program proposed in the manual was one immediate answer to the demands of the military services for young men who possess the "strength, stamina coördination, endurance, and agility" required for efficient performance, and even for survival, in combat duty. The strenuous physical activities outlined are for healthy boys and girls. As a guard against indiscriminate participation by those unfit for such activity, a carefully worded chapter was prepared by the Public Health Service on "Selection of Pupils for Training." As a guard, also, against any tendency to consider this a total physical fitness program, a section is devoted to a brief discussion of other phases of the school program which help in the development of physical fitness.

Since the physical education manual is now well known, discussion here will be limited to the considerations of the health education committee and the manual which was the outgrowth of these considerations.

The job before the Committee on Wartime Health Education for High Schools was clear. Six and one-half million young people are in secondary schools today, 6½ million pupils who are the nation's major source of wartime man power. What immediate action could the schools throughout the nation take toward producing "the

sound and well functioning bodies, the wholesome attitudes of mind, and good habits of living necessary to the development of physical strength and endurance and the specific knowledge and skills demanded of youth " today?

Obviously, more is needed than an expansion of health services and medical care programs, important as these are. Moreover, under wartime conditions professional health and medical services may necessarily be curtailed rather than increased. Yet here is a group of young people suddenly faced with adult responsibilities. The secondary school health program must be concerned not alone with doing something for them. It must give them opportunity to act for themselves—to develop in themselves a responsibility for their own health and the protection of the health of others. This is important not only in relation to general measures for health protection and improvement, but also as preparation for specific wartime services, whether civilian or military. High school boys and girls need experience in identifying sanely their own health problems, the health problems in their schools, homes, and community, and those in the services for which they are preparing. They need also experience in learning how to meet these problems intelligently. Sound health education is essential to accomplish these results.

This, then, was the task of the committee—to give what stimulus it could, through the medium of a wartime manual, to the development of more adequate and more dynamic health education in secondary schools in accordance with wartime needs. The committee, though focusing on the special contributions of the school, recognized that health education responsibilities in respect to secondary school problems must be "shared by all members of the school staff as well as by health departments, medical

groups, parents and others in the community." Fully as important, it recognized that no manual, however much it reflected the best thinking on a problem, could in and of itself be the magic wand which would effect health improvement. The desire for improvement and the will to act must be within the local communities themselves. A health education manual prepared for nation-wide use could at the most be only supplementary to local action. It could help direct attention to major problems in wartime, but even these vary widely in different sections of the country and in different communities. It could suggest specific courses of action to meet common problems, but here again the steps developed locally through coördinated planning are those which are likely to work best because of their local applicability.

The health education manual thus prepared within these recognized limitations is designed to serve as a curriculum guide for teachers, and as a source of ideas for administrators who are responsible for putting health education programs into action. Six major health objectives were selected for emphasis in the manual. They are: correction of remediable defects, prevention and control of disease, better nutrition, prevention of accidents, efficient daily routines and sound mental attitudes. There is nothing new in these objectives. They are as important in peace as in war. Certain aspects of each, however, when considered in a wartime setting have potential value in motivating young people for better health behavior. Consequently, for each objective pertinent information on the problem as it relates to high school youth in wartime is given, and "suggestions for action" which are in fact ideas that may be incorporated in a health instruction program by direct or integrated teaching.

An important section of the manual

contains suggestions for helping students meet health objectives for special wartime services. Material appropriate for use in preinduction training in health and sanitation for military services was contributed by the Army and Navy. Other material dealing with health problems now confronting youth in industry and agriculture was furnished by vocational leaders and by the Children's Bureau. A public health nurse was responsible for a chapter devoted to health preparation for community services, such as child care and clinic services and home care of the sick. No attempt will be made here to outline the content of the manual in any detail, for it would only be repetitive of the manual itself. Illustrations from the fields of nutrition, and of preparation for military services will suffice to indicate the type of emphasis given.

The significance of good nutrition as a factor in maintaining the nation's man power through its contribution to efficiency and health is widely recognized today. Less recognized perhaps is the part which high school students can play in a broad nutrition program. It was the committee's belief that student participation may be threefold: (1) improving personal nutritional status by following day by day the practices leading to good nutrition; (2) cooperating in the national and home food conservation program, and (3) assisting with such wartime nutrition programs as group feeding or school lunches.

Many high school students today are doing most of the family food shopping and cooking. Therefore, the committee felt that a practical health education program in the school should give students knowledge and training to assume this responsibility with efficiency. For example, students may design a meal record card to use in appraising their own or their family's eating habits.

They may plan meals for members of the family working in the "swing shift" or the night shift, and they may demonstrate the packing of a suitable noon-hour lunch for themselves, for a younger brother or sister, or for a member of the family working in industry. An appropriate school or home activity for students living in congested war areas, or for those soon to be living on their own would be to plan and prepare simple meals that require minimum working facilities, little work space, and a limited amount of time. Activities like these, if intelligently carried out, will require careful study and research on food values and food requirements, and thus have real educational value.

In the nation-wide food conservation program high school students may find a thoroughly practical field for wartime service, the performance of which will contribute in a realistic way to their own, their family's, and the community's nutritional needs. Growing and using victory garden products; canning, drying, and storing foods; preparing foods to conserve their food value and learning how to buy wisely, are all tangible activities suitable for high school students. To illustrate, students may figure how to plan nutritious meals under rationing and with food shortages and find it as much of a game as the busy housewife does a puzzle. In some schools such projects are carried on through organized groups, as the Victory Corps, in recognition of the need at this age level for doing things together with others of the same age or interests.³ In the health education manual are found many suggestions for student participation in worth while nutrition projects such as these just described.

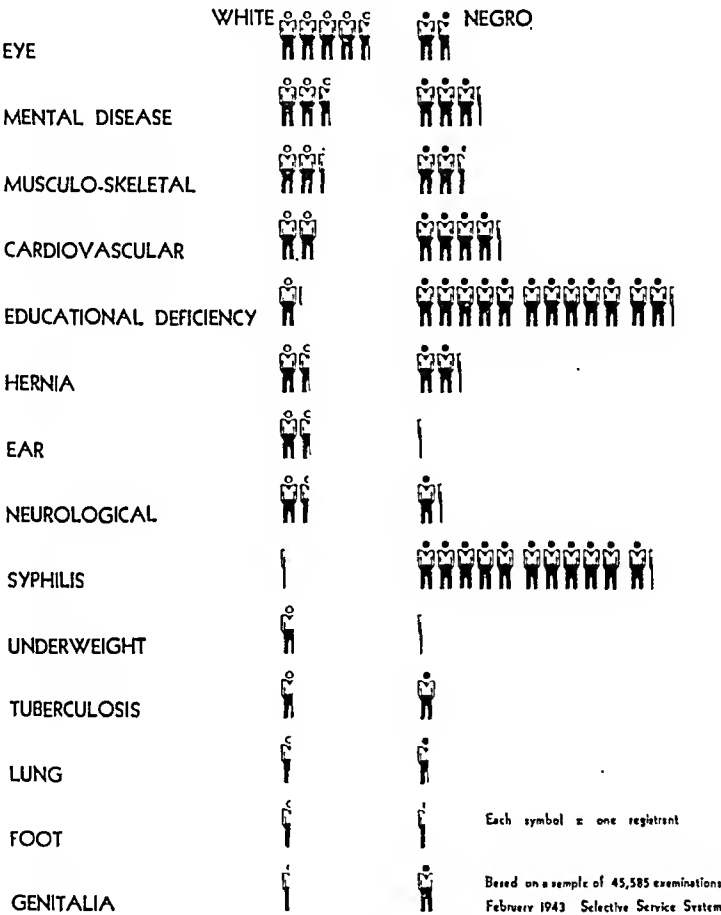

"The problems inherent in military life indicate that pre-induction training in health and sanitation will be of definite assistance. This opinion represents the thinking of military officers with field experience as well as those

MAJOR CAUSES OF REJECTION AMONG

U. S. OFFICE OF EDUCATION

charged with training responsibilities. Time is restricted in the Army and Navy for the teaching of health. Consequently, any reinforcement which can be given to this instruction prior to entrance to military services will be of great aid."

Five fields of training as suggested by Army and Navy representatives are discussed in the manual. They are:

1. A knowledge of the body with emphasis on organs especially susceptible to disease and injury.

2. A knowledge of the common communicable diseases, and steps needed for group and individual protection against their spread. Development of a readiness to cooperate in disease control measures.

3. Development of attitudes and skills needed to prevent accidents and to give emergency care.

4. An adjustment to military life which will involve willing acceptance of responsibilities and cooperation with other men in all activities.

5. Intelligent action in respect to other problems of military hygiene that will result in protection and promotion of individual

health and in the maintenance of group health.

These fields, similar in many respects to the objectives outlined previously, were determined through an analysis of military needs, and represent a common denominator as valuable in the training of an infantry gunner as of a pilot. In certain services, such as the air corps or tank corps, special health training may be needed over and above the basic training, however.

The differentiated kind of instruction believed desirable as a background for those soon to enter the armed services can be well illustrated in connection with education in the prevention and control of disease. All high school students, the committee felt, need instruction in regard to such specific diseases as the common cold, tuberculosis, malaria, smallpox, syphilis and gonorrhea, typhoid fever and typhus, all of which may have special significance in wartime and an understanding of which will give concreteness and reality to the cause, spread, prevention, and control of diseases in general. As a part of preinduction training, however, additional problems particularly pertinent to military life need emphasis. These include: (1) understanding of conditions which exist at training centers and at the battle front that are conducive to the spread of infections; (2) understanding of measures taken to protect the men and women in the services and consideration of how one may cooperate in these measures; and (3) special responsibilities of the individual soldier or sailor on field service in such matters as purification of water supplies, sanitary disposal of body wastes and self-protection from disease-carrying insects. Many details in regard to such problems will wisely await instruction after induction. However, a degree of conditioning now should help create a willingness on the part of future

inductees to cooperate in the military health program. According to the committee, worthwhile experiences for the students while still in school may include assistance to local health departments in disease prevention and control activities, and also week-end field marches and camping trips under trained leadership during which principles of sanitation and personal conduct required of military men may be applied.

Another preinduction problem of major concern is the development in men and women of the ability to maintain sound mental attitudes in situations which are inevitable in military life. Young people need to learn how to face facts realistically and to become aware of situations they must meet, as well as of possible ways of adjusting to and finding their places in the armed services. This of course is equally important in civilian life. The times demand that young people grow up quickly. The school program as indicated earlier, must therefore provide opportunity for them to make decisions and take responsibilities. The health education manual contains many suggestions for ways of doing this in respect to the solution of health problems. Guidance counseling to help each find the place where he can most effectively serve in the war program is also essential. A recent Victory Corps publication⁴ deals with this problem in detail.

Administrative provisions generally recognized as essential for effecting a dynamic health education program were outlined in the manual by the committee. Briefly summarized they are:

1. *Fixing responsibility*—Acting on the belief that "what is everyone's business soon becomes no one's business," the committee recommended that in each school "one person be given the responsibility for coordinating all school health activities and for relating them to other health activities in the

community. The individual chosen for this task may be the school medical adviser or nurse, or the best qualified teacher available. Whoever is selected should be given time for this work and should have the support and advice of a school health committee.

2. *Providing time and opportunity for health instruction*—In order to accomplish this important wartime job of helping young people become fit, as well as of laying the foundation for future good health, there is great urgency for carefully planned instruction based on the needs and interests of the students. Students during the 9th and 10th grades need orientation in the high school health program. They need assistance in analyzing their own health problems and in working out plans for personal health improvement. During the 11th and 12th years they need, in addition, help in planning ways of living which will enable them to meet the demands of adult life, and now particularly to meet health and safety problems associated with military services, industry, agriculture, and community services. Direct health teaching, the committee believed, is essential in order to fulfil these responsibilities. Ample preparation, they stated, would involve 5 periods of direct teaching per week, or the equivalent, for at least one semester during the 9th or 10th grades, and a similar amount of time again during the 11th or 12th grades. In addition, implications for health teaching should be fully explored in all subject matter fields.

3. *Finding health needs and problems and providing follow-up procedures*—Teacher observations, special tests, and medical examinations all aid in discovering individual health needs, and form an integral part of a functional health education program. With a depletion of civilian medical and nursing services, more and more responsibility for this phase of the health program is already falling on teachers. This fact makes it important that they receive instruction on how to observe students for deviations from normal health. In follow-up procedures special attention should be given now to students seeking to qualify for particular wartime services. A boy with marked visual defects, for example, should be discouraged from preparing to be a pilot. Students attempting some form of war work in out-of-school hours will require close observation and supervision to make certain this work is not proving detrimental to their health.

4. *Providing a school environment conducive to health*—Physical conditions of the school plant as well as the emotional at-

mosphere of the school have an influence on student health. These receive emphasis in the manual, but will not be summarized here.

5. *Training of personnel*—One of the greatest obstacles to an effective health education program is the lack of adequately trained teachers. The committee, accepting the fact that many schools will not have specially prepared health educators available, suggests specific ways in which persons chosen for the task may secure additional in-service preparation. Further and more detailed suggestions are contained in a recently published report of another committee appointed by the U. S. Commissioner of Education to consider this problem. This report, "Preparation of Teachers for the Program of Physical Fitness through Health Education" appears in the June 15, 1943, issue of *Education for Victory*, the official bi-weekly publication of the U. S. Office of Education.⁵

6. *Community relations*—The health education manual ends with many specific suggestions for contributions to the health education program by community groups.

In health education no activities of the school can be thought of as apart from those of home and community. Joint action, carefully planned, is paramount in the improvement of student health. In this action the health department should hold a prominent place through helping schools determine the most significant health problems which education can help to solve and through making its technical services available to schools for consultative services on technical matters, and for in-service teacher training.

Health Education in Action

A. OPPENHEIM, M.D.

Director, Bienville Parish Health Unit, Arcadia, La.

BEFORE April, 1942, Roberson Community, a typical rural Negro settlement in Bienville Parish, La., had barely utilized the services of the county health unit. Of the 55 families that made up this community, several had brought infants and youngsters to child health conferences; first graders had been visited annually by the Health Director for purposes of vaccination; some few had received typhoid vaccine, and a few others were undergoing treatment for syphilis. This constituted the total contact with the health unit. The majority of families were hardly aware of its existence. The fact that the health office was 40 clay-road miles distant, with only a part-time suboffice in the nearest town (6 miles away) did not help.

But one year later this same community had built its own health building, had someone from each family actively engaged in health work, and had changed the name of its school to include that of the new health clinic. The Roberson Colored School, center of community activities, is now known with pride as the Roberson Consolidated School and Health Clinic.

How was this change from comparative apathy to deep interest effected? Chiefly by drawing on the resources of the community itself and by accompanying every step of a planned health program with an educational campaign designed to make each community member "health-active" and "health-literate." Since this community is typical of many in the South, a study

of how this program was put into action may stimulate health efforts in similar groups, and is hence reported in some detail.

COMMUNITY BACKGROUND

Roberson Community is composed of 45 families, numbering about 300 people. The homes and farms spread over several square miles of cotton country, with a central church and school which serve as assembly-places for this closely knit group. The typical head of family is a share-cropper or small independent farmer who has lived all his life in Louisiana, most of it in this community. He has a family of 4 or 5, and rarely sees more than a few hundred dollars each year in cash. He may own a few chickens and have his own garden. Sanitary conditions are inadequate—no bathrooms or indoor toilets—screening in only six of the homes—water drawn from wells often poorly constructed—milk unpasteurized. This composite picture is based upon social studies made of each family, the details of which were painstakingly gathered on form sheets by the Executive Health Committee which was elected by the community.

GROUNDWORK

The health clinic project in Roberson Community was a direct outgrowth of a parish-wide observance of National Negro Health Week (April, 1942). It has always been our policy to work very closely with the schools, both negro and

white. Through them, we are able to reach every family. In addition, we have the coöperation of leaders trained in technics of education and publicity. We therefore requested the Negro supervisor of schools to call together the parish faculty members, and we suggested to them a variety of suitable activities to be initiated by the schools in each community for Negro Health Week.

Reports on the week's activities were sent in to the health unit by 40 of the 56 Negro schools in the entire parish. The following is a sample report from the high school attended by Roberson Community children, among others.

I. Total communities participating	10
II. Total homes participating	78
1. Cleaned house	78
2. Cleaned toilets	55
(others needed repairs, and promised to make them)	
3. Repaired and built window screens	35
4. Repaired windows and built same	36
5. Repaired and built steps	43
6. Filled in low places	44
7. Planted flowers	60
8. Piled and hauled cans	77

Assemblies and discussions on "Health and the War," exhibits and playlets, and health sermons in church were other activities. To stimulate further interest, each school (negro and white) was asked to submit a prize essay on Immunization. Parish awards of \$5 in War Stamps (donated by the local Tuberculosis Association) were given to the negro and white winners. Both essays were published in the *County Bienville Democrat*.

Interest in these various projects throughout the parish was so deep that we were encouraged to plan for a long-range program. We felt this could best be accomplished by a project in a selected community, using widespread publicity of its achievement as an incentive to other groups. Roberson Community was chosen because of its outstanding work during National

Negro Health Week. It had already laid the groundwork for a long-range program by setting up adult health committees.

THE PROJECT IS BEGUN

The adult health committees were asked to prepare reports for the Health Day exercises at church. Some of the topics covered were "Need for use of more milk," "House care in contagious diseases," "Home gardens and the war." As Health Director, I was invited to give the health sermon. I analyzed the local health needs, and suggested that the community plan with us a year's program of health activities. To engage the immediate interest of every member I proposed that the community build its own health clinic. Besides "interest" value, this would enable the group to receive more intensive services and would eliminate the long trip to the county health office. This suggestion was accepted with enthusiasm.

The school, as center of the community life, became the leading spirit in the program. The principal of the school and an elected committee of five undertook to design the plan for the clinic building and to raise the necessary funds. After the plans were approved by the Director of the Division of Health Education of the State Department of Health, volunteers from the community did the actual work of building. The committee decided to tax each member 50 cents. Since it knew intimately every family involved, greater leniency was shown to larger families and to those with lesser means. Fund raising was made the occasion for education on the need for and value of health services. Group meetings were held in the church; moving pictures were shown; families were visited individually by committee members when questions were answered. The few "contrary" members were con-

vinced. It cannot be overemphasized that this tax meant a real monetary sacrifice. Some of the farmers sold chickens to get the cash. A sum of \$75 was finally raised within the community. The balance needed (\$25) was secured from white people of the parish who were sympathetic to the project.

The clinic is a one-room structure, located near the church and school, in the cotton-fields, and easily accessible from the highway. Although it was not until March, 1943, that the building was completely finished, with glass windows and paint, it was sufficiently set up within 3 months after the Health Day exercises to be put to use.

HEALTH SERVICES FOR THE YEAR

No one in the community was able to afford *adequate* medical care, as we had discovered from our family studies. Therefore, health services were planned for all. Community leaders interested the members and secured their coöperation. The record of services for the year is a tribute to their resources of enthusiasm and coöperation.

The schedules for examinations and meetings were posted in advance in the health building, and announced throughout the school. Despite heavy cotton-picking time, clinics were well attended. The health unit personnel (2 nurses, 1 sanitarian, 1 secretary) assisted with the work, as needed. For a 2 week period the services of a physician from the State Department of Health were secured and those of a mobile dental unit promised. Examinations were accompanied by recommendation for correction, with request that appointment be made with private physicians where correction was needed. Tonsillectomies and adenoidectomies, however, were arranged for with Shreveport Charity Hospital at no charge to the community. Twenty-eight (all that were needed) were performed. As a

result of the tonsillectomies, 3 cases of hearing defect were also cleared up. The results of other activities of the unit are summarized in Table 1.

TABLE 1
Results of Work of Health Unit from April, 1942, to April, 1943
(Population of Community 300)

	Per cent of Total Number
<i>General Physical Examinations</i>	
Adults	65
Infants	100
Preschool children	90
School children	92
<i>Special Examinations</i>	
Chest x-rays (above 4 years of age)	75
*Wassermann tests on adults	65
Wassermann tests on high school students	100
Eye, ear, and dental examinations (children)	100
<i>Immunizations (Program for children only)</i>	
Smallpox	100
Typhoid fever	91
Diphtheria	100
Pertussis (infants under 1 year)	92
<i>Regular Health Supervision</i>	
Maternity cases	90
Infant and Preschool children	94
* 100 per cent of clinical cases under regular treatment 10 wells, 12 privies, and 3 houses were improved or rebuilt.	

VALUES OF THE PROJECT

The community attained a new level of understanding and interest in public health work. Each aspect of the program was used as an opportunity for clarification and education on such topics as immunization, serological tests for syphilis, prenatal care, etc.

The community developed a set of health standards and a respect and pride in its own capacity for achievement of specific health goals. The concrete acquisition of a central health building directed the health planning into long-range paths. The following

excerpt from "next year's plans" recorded by the school principal shows how much this group can now do on its own.

The committees are still functioning, along with another group that has been set up for this year. This latter committee is composed of school children located in different sections of the community, and we have 10 of them working in pairs, which make a total of 5 groups working the entire community. I have appointed them as leaders for their section. I have sub-divided the community into 5 health circles, and these girls will be busy, each pair in their respective districts trying to educate the people to the fact that it is necessary that they destroy all breeding places of flies and mosquitoes. We are giving prizes to the two girls who get the largest group of people to carry out these health objectives. Each two girls that are working together have 10 families or more under their care.

The interest of the white members of the parish was secured on the premise that health is indivisible; and that the health of any one family in a

community is necessarily the concern of all. Articles in the county paper, reports to the elected governing body of the parish, and coöperative planning with the school board promised interest in the project. The work of the local Red Cross in helping set up nutrition classes under the direction of Negro high school teachers, the request of the governing body for a report of National Negro Week activities; the donation of an award for the winning Negro essay on immunization, and the contributions made toward the health clinic building, all attest to the growing interest of the entire community.

CONCLUSION

From our work in this project we are convinced that there are many untapped resources of initiative, enthusiasm, and coöperation to be drawn on in both negro and white communities for successful health service and education projects centered on local needs.

Post-War Malaria Prevention by the County Health Department

WILFRED N. SISK, M.D., M.P.H.

Medical Director, Buncombe County Board of Health, Asheville, N. C.

THERE are large areas of the United States which have had known cases of malaria only infrequently during the past twenty-five years. These areas gradually became rid of malaria due to a combination of circumstances. Better farming and the passage of the small water-driven mill, together with increased efficiency of medical attention, have been factors. However, the present war is bringing about conditions which make it imperative that these large areas of the United States be reëxamined as to their potentialities for the spread of malaria.

The record of the last war gives us a lead as to what to expect during the course of and particularly following this war. During the last war very few American troops were engaged in any tropical territory. Our army fought in areas almost free of malaria and, as a consequence, we had no subsequent malaria problem. However, certain British and Russian troops fought in malaria infected areas. They took malaria to their homes, and the spread of the disease was recorded for the first time within the Arctic Circle in Russia.¹

In this war tremendous numbers of American troops are fighting in areas heavily infected with malaria. It is a distinct possibility that a large portion of the American troops who go overseas will spend at least some part of their service in tropical areas where they may well become infected with malaria. This being the case, it behooves those

of us in places where malaria does not ordinarily occur to be thoroughly familiar with the potentialities.

The first consideration is the possibility of the return to the United States of troops still harboring the malarial parasites. This brings up the question of the efficiency of the present treatments for malaria. There are three drugs of value: quinine, atabrine, and plasmochin. These drugs admittedly do not give us adequate control over the disease. Relapses are frequent and unpredictable.

A good illustration of the fact that troops do and will return still harboring the malaria parasite is the experience at the Moore General Hospital at Swannanoa, N. C., which is about six miles from Asheville. In a small contingent of injured troops returning from the South Pacific, 42 men had malaria infection as shown by blood smears.² These 42 cases were distributed according to type as follows: *P. vivax*—30, *P. falciparum*—3, *P. malariae*—1, and unidentified or unclassified—8. Twenty-six of the 42 men had attacks while they were at Moore General Hospital. Ten of this 26 had their first attack while they were here. One additional soldier had his first attack while enroute two days before arrival. The remaining 15 attacks represent relapses. It is interesting to note that in one of the cases of *P. vivax* infection the individual had his first attack 4 months after leaving the South

Pacific. Thus in a small group of soldiers, 42 were infected with malaria and 26, or more than half, had either their first attack or a relapse after reaching this country. In fact, there was an average of 4.5 relapses per patient. One patient has already had 12 relapses. If this is a sample of what will occur in the remainder of the war, it will be a small county indeed which will have as few as a hundred cases of malaria among returning soldiers.

The second condition, and perhaps the more important one, is the potential means of spread of malaria from the infected reservoir to the general population. It is at this point that the problem demands the close scrutiny of the health department. Even though his estimate may be in error, the health officer owes it to himself and to his community to make an estimate of the potential danger in his community. For his own protection he should make this estimate a matter of record and present it to his local board of health.

Before going into detail in the discussion of this estimate, it might be well to consider one additional factor present in areas where little or no malaria has occurred in recent years. That factor is the lack of familiarity of the practising physicians with the disease of malaria. Lest it seem far-fetched to think that physicians might not be on the watch for this disease, let me cite an example. A relative of mine was trained as a laboratory technician in a part of the South where malaria is not uncommon. Later she was employed in a large New York hospital where she became ill. She had the usual attacks of chills, fever, and prostration. Numerous specialists were called in, but none made a diagnosis. During her periods of prostration she was completely out of her head. In between her attacks she called for a microscope and blood smear and made her own diagnosis. As it happens, she

contracted malaria in the New York harbor while visiting friends aboard a boat which had just returned from the Caribbean. She was bitten by a mosquito on this boat.

In making a survey of any area it is necessary to have exact knowledge concerning the distribution of mosquitoes in that area. Mosquitoes, of course, cannot spread malaria unless infected persons are present. In most of the areas under consideration, malaria was greatly reduced, if not eliminated, by the reduction in the number of mosquitoes. In recent years, however, there may have been a great change in the mosquito population without being reflected in cases of malaria. The only way to be sure is to make an actual field survey. The U. S. Public Health Service has sufficient entomologists to aid the local health department in making the primary survey and to give the local personnel sufficient knowledge so that they can carry on the needed follow-up work.

In the case of Asheville and Buncombe County, North Carolina, the problem has come more quickly than in most places. We have a 1,500 bed Army hospital in the Moore General Hospital at Swannanoa. The Navy is represented by a convalescent hospital designed to care for an additional 500 men. A branch of the Army flight control is located in Asheville. Certain personnel of this branch go to and from tropical areas frequently. Additional facilities for convalescent military personnel are in prospect. Thus, while only 42 known cases of malaria have been imported into this county, the probability is that many more will come.

Three additional pertinent facts were known to the local health department. The medical staff at the Moore General Hospital reported that they had found *Anopheles* mosquitoes in the vicinity, and several years ago 10 cases of ma-

laria were definitely known to have been contracted locally following the importation of one case from Eastern Carolina. Mortality records for Buncombe County are available from 1919 to 1943. While no deaths from malaria have occurred since 1937, there were 13 deaths from this cause between 1919 and 1937. Seven of these occurred between 1933 and 1937. Thus the possibility of the spread of malaria was definitely realized.

An entomologist from the State Board of Health spent several days on two occasions with the Health Department investigating the probable future problem. The survey included the search for adult mosquitoes as well as breeding places. Needless to say, the local personnel had never had occasion to look for *Anopheles* mosquitoes. It was pointed out that the *Anopheles quadrimaculatus* was the only mosquito in this area likely to spread malaria, and the identification of this mosquito was explained in detail. Likely resting places of adult mosquitoes were inspected in all parts of the county. Numerous culverts, bridges, stables, and pig pens were carefully gone over. As is well known, the *Anopheles* mosquito seldom flies more than a mile from its breeding place. Consistent with this knowledge was the finding of adult mosquitoes within a mile of certain lakes and nowhere else. It is perhaps significant that the 10 cases known to have been contracted in this county during 1936 all lived within less than a mile of one of these lakes. Repeated visits to this particular lake have never failed to show the presence of *Anopheles quadrimaculatus*.

Numerous dippings were made in still waters along creeks and in various lakes. Many *Anophelene* larvae were found, some of which turned out to be *Anopheles quadrimaculatus*. Since the differentiation between the larvae of the various species of *Anopheles*

mosquitoes is rather difficult, it was decided to send any later collections of *Anophelene* larvae to the State Board of Health for final identification.

The climate of the particular community under consideration must be taken into account in making the survey. The mountain waters around Asheville stay sufficiently cold to prevent much mosquito breeding until the latter part of June. Monthly inspections are to be made each year at numerous scattered points throughout the county from the latter part of June until the end of the breeding season, which is usually about the first of October. The night temperatures during September range as low as 36°, thus definitely limiting mosquito breeding. More frequent inspections are being made in areas where *Anopheles* mosquitoes are known to exist.

Definite action is being taken in the two places where the *Anopheles quadrimaculatus* has been found. As it happens, these two places are in localities frequented daily by military personnel. One place is within 400 yards of the Moore General Hospital, and the other is adjoining the municipal recreation park. A combination of oiling and variation of the water level of the lakes is being used.

This survey has shown the local health department some interesting things. Six major lakes and two pools were known to the Health Department before this survey was made. In going over the county with mosquito breeding in mind, three additional small lakes and four areas where water collects in wet weather were found. A practice which is growing in popularity is the making of small fish ponds to grow edible fish. Several of these were found with considerable vegetation around the edge. As it happens, no mosquitoes were found breeding in these fish ponds, probably because of the fact that the mountain waters feeding them usually

stay at a temperature of about 50° F. These fish ponds are potential menaces, however, and do cause trouble in other sections of North Carolina.

SUMMARY

1. It has been shown that there is an almost certain possibility that troops infected with malaria will return to all sections of the United States. It is very likely that there will be numerous infectious relapses among these men.

2. The need for a resurvey of the potential malaria spreading mosquito population was shown. It was pointed out that large changes in the mosquito

population, both as to numbers of mosquitoes and types, are possible in many areas without being reflected in increased cases of malaria.

3. The method of making a survey consists in looking for both adults and larvae of *Anopheles* mosquitoes. Expert help will be needed in areas where mosquito control has not been necessary in recent years.

Removal of Poliomyelitis Virus from Sewage by the Activated Sludge Process and the Separation from Sludge of an Antibacterial and Antiviral Substance

HARVE J. CARLSON, M.S.P.H., AND CHARLES F. MCKHANN, M.D., F.A.P.H.A.

Department of Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor, Mich.

IT was reported in a previous communication that activated sludge as used in sewage disposal processes largely removed poliomyelitis virus from the supernatant liquor. Sludge in amounts of 1,100, 2,200 and 3,300 p.p.m. at 6 and 9 hour aeration periods, removed the virus sufficiently from the supernatant to make it almost completely noninfective when injected intracerebrally into mice.¹ The present report describes the separation from activated sludge of an antibacterial and antiviral substance.

SEPARATION OF AN ANTIBACTERIAL AND ANTIVIRAL SUBSTANCE FROM ACTIVATED SLUDGE

Antagonistic relationships¹⁴ between different types of microorganisms have come recently into prominence. Fleming¹⁵ and others¹⁶ have found an active substance in the filtrate of cultures of *Penicillium notatum*, which is active against many Gram-positive organisms both *in vitro* and *in vivo*. Dubos¹⁷ isolated an enzyme from soil bacteria which was active against the pneumococcus and other Gram-positive or-

ganisms. Later Dubos and coworkers¹⁸ produced a specific antibacterial compound in crystalline form from spore-forming bacteria. It is possible that there may be such antagonistic relationships between organisms in sewage and the agents in activated sludge mixtures. *Eberthella typhosus* and *Salmonella paratyphi* have been observed¹⁹ to exist only a short time in sewage sludge, while a reduction of 99 per cent in the numbers of these organisms was noted to occur in activated sludge after 6 hours' treatment.²⁰

As noted above, poliomyelitis virus has been found to be removed or destroyed in sewage by the activated sludge process. The separation from sewage sludge (mixed liquor) of a substance with antibacterial and antiviral activity is herewith described.

PREPARATION OF EXTRACTS

Fresh activated sludge and return sludge were obtained from the local sewage treatment plant. These materials were collected in sterile 4 liter containers and brought immediately to the laboratory.

Numerous preparations derived from dried activated sludge were made through extraction with various solvents, but all proved ineffective when tested for bactericidal and virucidal activity. Wet activated sludge was tried in a similar manner, again with negative results.

In the second phase of the study, fresh activated sludge was incubated at 37° C. for varying periods. In some samples, the effluent or supernatant was transferred to suitable containers and incubated separately. The settled solids (floc) were used to fortify other samples. The sludge was thoroughly mixed for 15 minutes to obtain an even suspension before being transferred to flasks for incubation.

The time necessary for the development of maximal antibiotic effect was found to be approximately 100 hours' incubation at 37° C.

At the end of the incubation period, the effluent was siphoned off into 250 ml. centrifuge bottles and centrifuged at 3,000 r.p.m. for 30 minutes. The supernatant, free from particulate matter, was transferred in 100 ml. amounts to separatory funnels. To each was added 15–20 ml. of ethyl ether and the funnel was then shaken for 3 minutes. After the period of agitation, three layers separated, an ether layer, an aqueous layer, and a jelly-like interphase layer. The ether layer was found to contain an active substance and was designated Extract A. This material, from which the ether has been removed by evaporation at room temperature or at 50° C., was called Extract C.

Extractions were made with chloroform (Extract B) in much the same manner as with ether. Evaporation of chloroform was accomplished at 85–90° C. in a water bath.

Samples of ether extract (C) were taken up in a 2 per cent sodium bicarbonate and then neutralized with acid (5 per cent acetic) to a pH of 7.0 (Extract D).

Each of these 4 types of extracts, ether (A, C, D) and chloroform (B) was tested for antibacterial properties, and the two ether preparations (A, D) were tested for antiviral activity.

METHOD OF TESTING ANTIBACTERIAL ACTION

The concentrated ether extract (A), the chloroform extract (B), ether extract residue (C), and sodium bicarbonate treated residue (D) were tested for antibacterial properties as well as were similarly prepared extracts of two bacterial cultures, *Escherichia coli* and zoögleal.

Twenty-four hour broth cultures of recently isolated strains of *Staphylococcus aureus* hemolyticus and *E. coli* were seeded to nutrient agar plates. Sufficient numbers of organisms (0.3–0.6 ml. of broth culture) were used so that a 24 hour incubation gave growth that masked the plate. The surface of the agar was allowed to dry in air for 15–30 minutes to remove all visible moisture.

The extracts were placed directly on the top of the seeded agar. Several drops (2–3), Extract A, B, were allowed to evaporate before the Petri dish lid was replaced. Extract C taken up with nichrome loop was also placed on the seeded agar surface. The amount taken up was that portion that remained on the edges of the nichrome wire. These plates were incubated at 37° C. for 24 hours and inhibition areas were noted.

The amount of antibacterial substance present was indicated by the degree and extent of inhibition. The presence of an active substance would be indicated by complete inhibition or destruction of the growth of all organisms on the exposed area through the depth of the agar. Fanning out of the inhibition zone from the exposed area could be recorded in terms of cm. of inhibition.

METHOD OF TESTING ANTIVIRAL ACTION

A strain of poliomyelitis virus adapted to mice was used. Inoculations were made intracerebrally in amounts of 0.03 ml. of virus suspension (1:300) unless otherwise stated. Mice were observed at least once daily for paralysis or other evidence of illness. All groups were observed for a period of 30–40 days following the inoculations before the protocol was completed. The original virus suspension was obtained by removing the brains and the cords of mice paralyzed in two or more extremities. These were ground in refined silica and suspended in sterile broth. After centrifugation for 5 minutes at moderate speed, the supernatant (1:5) was removed and used as virus concentrate from which dilutions were made.

In Experiment I, Extract A was mixed with virus to yield a 1:300 virus suspension. This extract-virus mixture was thoroughly shaken and placed in the refrigerator for 2 hours. Ten minutes before the end of the test period, it was again thoroughly mixed. The aqueous layer was then inoculated intracerebrally into mice. Another portion of the virus suspension was treated with ether in a similar manner to serve as a control.

In a second experiment, smaller amounts of Extract A were mixed with the virus suspension and the contact period was increased to 18 hours. The amount of Extract A used was 10–15 per cent of the total virus suspension. After the addition of Extract A to the virus suspension, it was shaken gently for 30–45 minutes, following which it was placed in the refrigerator for 18 hours. The aqueous layer was then removed aseptically for intracerebral inoculation into mice.

Aeration is part of the activated sludge process of sewage treatment, and it was thought that this might be necessary to enhance the activity of an

antiviral substance derived from sludge. With this in mind, Experiment III was set up using Extract D. Extract D was mixed 1:1 with the virus in three portions. To the first was added a minute amount of 30 per cent hydrogen peroxide (Superoxol). The second tube was aerated by passing air through the mixture for 4 hours. The third tube contained only the mixture of Extract D and virus suspension. The first and third tubes were placed for 2½ hours in the refrigerator while the aerated tube remained at room temperature. Controls employing virus suspension alone and virus plus an identical amount of 30 per cent hydrogen peroxide were also included. The lack of virucidal effect of aeration had been previously demonstrated.

DESCRIPTION OF THE EXTRACTS

The residue, Extract C, obtained when Extract A was evaporated, was a dark brown oily substance having a distinct, pungent odor. It was soluble in ether and chloroform but not in water. A faint yellow color was present and increased in intensity with concentrations.

Extract B appeared colorless, possibly due to the small concentration obtainable in chloroform. When Extract B was evaporated to dryness, minute amounts of oily residue were observed which had the same characteristic odor as Extract C. The material appeared to be thermostable since the separation of the Extract B was made at a temperature of 85–90° C. for 30 minutes.

A crystalline material has been separated from Extract C on several occasions. The antibacterial but not the antiviral properties of these crystals have been tested.

RESULTS

Antibacterial Tests

The ether extract (A and C) when placed on the surface of heavily seeded

FIGURE 1—Antibacterial Action of Extract A

FIGURE 2—Antibacterial Action of Extract C

agar plates, destroyed all the organisms in the areas exposed through a depth of $\frac{1}{8}$ in. or more of agar (see Figures 1 and 2).

In Figure 1, the ether extract (A) of the effluent from activated sludge was placed on the surface of the seeded agar. The area of inhibition is apparent. The residue precipitated on the agar within the inhibition area appears as a light grayish material. No growth of organisms was observed below or in the inhibition zone. Figure 2 depicts the action in two areas of the plate of the residue, Extract C, which was placed on the surface by a nichrome loop. The original inoculum was placed directly in the center of the plate and appears in the figure as a light line in the inhibited zone. The loop was again placed on the surface to the left of the original contact and appeared as a slight line in the inhibited zone.

The bactericidal activity of the substance appeared to penetrate into the agar. The zone of penetration was directly proportional to the amount placed on the agar surface.

Extract B gave similar results but the degree of inhibition was not as pronounced as that of Extract A. The inhibition was in the area exposed, with

penetration only partially throughout the depth of the medium used ($\frac{1}{8}$ in.).

The crude substance, Extract C, and the ether extract (A) appeared to be slightly more active against the Gram-positive organism than against the Gram-negative organism though there was definite inhibition of both.

Controls of ether and chloroform were used in all experiments in place of the corresponding extracts with no inhibition of growth taking place.

The antibacterial action of Extract D was not as pronounced as was the effect of Extracts A and C. Surface growth was inhibited but there was only partial penetration into the seeded agar.

Greater amounts of the substance were found in effluents in which extra quantities of activated sludge floc had been incubated than in the effluents incubated without floc. Similarly prepared extracts of *E. coli* and of zoögleal organisms did not appear to contain the antibacterial agent.

Antiviral Tests

Paralysis in one or more animals in any test group was deemed to be indicative that the virus had not been destroyed by the extracts. Animals

dying 1 to 3 days after inoculation were considered to have died from trauma or interfering toxic substances.

The results of all the tests for antiviral action on poliomyelitis virus are shown in Table 1.

paralysis, and 6 died without paralysis being observed. Three deaths occurred within 2-4 days after inoculation. In the control groups receiving virus treated with corresponding amounts of ether, of 20 animals, 8 were observed

P = Paralyzed
D = Died without Paralysis
Dis = Discards
* See Explanation in Text.

In Experiment I (Table 1), of 20 animals receiving virus suspension that had been in contact with Extract A for a 2 hour period, 1 animal was observed with paralysis, 5 died without paralysis being observed, and 14 remained alive. Four of the deaths occurred within 3 days after inoculation and were thought to be due to trauma or toxicity as the one animal developing paralysis did so only after 18 days' incubation. In the control group, of 20 animals receiving an ether treated virus suspension, 10 were observed with paralysis, 3 died without paralysis being noted.

In Experiment II, the length of contact between Extract A and the virus suspension was increased to 18 hours and the amount of extract was reduced to 15 per cent of the volume of the virus suspension.

Of 21 animals receiving the treated virus suspension, 3 were observed with

with paralysis while of the control animals receiving virus alone (1:250), 9 were observed with paralysis. Of the controls receiving the 1:5 virus suspension, all became paralyzed or died. The extract as used in this experiment seemed of little effect.

Extract D was prepared in order to try to increase the solubility of the material and hence to insure more thorough contact with the virus. Constant shaking and agitation was not employed when Extract D was used. The results of the action of Extract D against the virus are shown in Experiment III, Table 1.

Of 30 animals receiving Extract D-virus mixture, 10 were observed with paralysis, and 4 died without paralysis being observed. When hydrogen peroxide was added as a source of oxygen with Extract D-virus mixture, no animals, of a group of 30, were observed with paralysis and 2 died

without paralysis. Of the 30 mice used in the control group in which the virus was exposed to the same amount of hydrogen peroxide, 10 animals were observed with paralysis, and 3 died without paralysis. In the aerated Extract D-virus mixture, 1 animal of 30 was observed with paralysis, and 1 animal died without paralysis being observed. Aerated virus suspensions were not included as controls in this experiment, as aeration for long periods had previously been shown not to affect the virus. The untreated control (1:300 virus suspension) caused paralysis in 13 mice, with 3 mice dying without paralysis.

While it seemed that some antiviral effect was exerted by the ether extracts, much clearer results were observed when the ether extract residue treated with sodium bicarbonate was used in the presence of oxygen or aeration.

SUMMARY

The activated sludge process of sewage treatment in aeration periods of 6-9 hours has been found to remove or to destroy poliomyelitis virus. Efforts to separate from the sludge (mixed liquor) an active principle have yielded a substance which exhibits antibacterial and antiviral action. The yield of the substance is increased by incubation of sludge.

The substance is soluble in ether and chloroform and is relatively insoluble in water. It appears to withstand a temperature range of 4°-85° C. without denaturation.

The material was found to have antibacterial properties when placed in direct contact, on a seeded agar plate, with organisms both Gram-negative and

Gram-positive. Activity was diminished when the crude substance was treated with sodium bicarbonate and subsequently neutralized to pH 7.0.

The material in the form of an ether extract appeared partially to inactivate a mouse-adapted poliomyelitis virus. The ether extract residue treated for brief periods with sodium bicarbonate and subsequently neutralized seemed almost inert, but the activity of this fraction was enhanced by the presence of oxygen or by aeration.

The source of the material has not been determined but it is apparently not produced by *E. coli* or zoögleal organisms.

The Public Health Significance of the U. S. Cadet Nurse Corps

LUCILE PETRY

*Director, Division of Nurse Education, U. S. Public Health Service,
Federal Security Agency, Washington, D. C.*

THE country's nursing shortage must be attacked as a production problem. As essential to the war as are planes, guns, and ships, the nurse is a guardian of the national health and the welfare of our fighting men.

Passed unanimously by the Congress in June of this year, the Bolton Act is keyed in its administration to the production of more nurses in a record period of time. The production goal for 1943 has been set as 65,000 new student nurses.

To provide the same amount of nursing care per patient in 1944 as in 1941, 115,000 new students would have to be admitted to schools of nursing this year. The compromise number, 65,000, was necessitated by the realities of the situation. This figure is a minimum which must be met unless the machinery of the nursing services is to break down. By whatever number the goal is surpassed, hospitals and public health services will benefit in direct proportion. If the goal is not met, every hospital and public health service will feel the pinch more this year and even more next year.

Public health services are vitally concerned with the adequacy of nursing care in hospitals. The public health of the nation depends upon proper medical and nursing care. This care is a basic consideration in maintenance of the public health.

Most of the 1,300 nursing schools, or production plants, in the country are operated by hospitals. A complete business cycle is represented in this system of operation. The hospital is the owner and operator of the plant and among the chief consumers of the product, which is the graduate nurse, and of the by-product, the student nurses' services. Hospitals without nursing schools are dependent on the 1,300 manufacturing plants. The success of the 1,300 schools in meeting the 65,000 goal will have a very direct bearing on the continuing existence of some of the 6,500 hospitals and of the continuing services of many.

During wartime, the federal government becomes a large consumer of nurses and leaves the hospitals with a shortage. Also, the government is concerned with the public health on the home front in its application to industrial production and its effect on the morale of the armed forces. As a consumer, necessarily concerned with the output, the government, through Congressional action, has stepped in as a financial investor in the nurse production plants.

In giving financial assistance in the production of nurses, the government has found it wise to use existing schools operating their own policies. The schools are responsible, under the Bolton Act, for admitting more students

and preparing them in shorter time. Production in the U. S. Cadet Nurse Corps of the same quality of nurses as before should evolve from this acceleration. Educational standards will be maintained.

Under the accelerated training programs required for the Corps by the Bolton Act, all essential instruction and experience must be condensed into 24 to 30 months. An extra 6 to 12 months of supervised practice is provided if required for registration by the state or for graduation by the school. This additional time is known as the Senior Cadet period.

The Senior Cadet may be transferred to a civilian hospital, federal hospital, public health agency, or may remain in the "home" hospital to replace a graduate nurse.

Public health and visiting nurse services will benefit directly by procuring Senior Cadet nurses, who have received full classroom and clinical experience and are available for full-time practice under supervision. It should be understood that the type and kind of supervised experience must be acceptable to the home school and the State Board of Nurse Examiners. Public health agencies, desirous of procuring the services of Senior Cadet nurses, should deal directly with the nursing schools in their areas.

On reaching the senior period, Cadets leave the ranks of students and make way for new students. Production will be increased through accelerated programs only if the Senior Cadet is removed from the school's housing and educational facilities. Retention of the Senior Cadet in the school would be comparable to the clogging of an assembly line with completed planes for six months.

Thus, shortening of the time element is the first step toward achievement of wartime production. Raw material to feed the processing machine must be

amassed next to make the speed-up economically sound. The U. S. Cadet Nurse Corps recruitment program is progressing very satisfactorily. By the end of September, almost 800 schools of nursing had been accepted into the Corps program. Approximately 80,000 students in these schools were expected to join the Corps, with about 41,000 of that number new students. More applications are being approved every day.

Recruitment has been supported by national, state, and local nursing councils, schools, hospitals, and others interested in the nursing profession. Information centers have been established in all hospitals to provide candidates with material on the Corps and on schools of nursing.

Acceleration and recruitment by themselves will not accomplish the production goal. They must be accompanied by expansion of educational facilities. As a beginning, existing facilities must be used to their greatest capacity, a capacity which is greater than many schools have yet recognized. Then, many schools have one bottleneck service which hinders maximum output. These must be removed by affiliation. Schools participating in the Corps must provide clinical experience in surgery, pediatrics, obstetrics, and medicine. Additions of a psychiatric affiliation by every school in the country would produce a 10 per cent increase in student enrollment in the year, if at the same time, the nurses' residences were kept filled. By negotiating new affiliations, the school improves and increases nursing services for its own patients and provides nursing service in the affiliating institution. Obviously, nursing care in psychiatric institutions would be greatly improved and the graduate nurse would be better prepared for the future. Other affiliations such as public health nursing and

communicable diseases offer parallel advantages.

Insufficient housing facilities must not be permitted to curtail student enrollment. Just as the factories of the country have met wartime demands, so the schools of nursing must avail themselves of every facility. They must expand their physical boundaries if necessary. Financial assistance for new construction or for alterations on a leased or purchased building may be secured quickly from the Federal Works Agency through the Lanham Act.

Schools are faced with still another impediment to expansion in the shortage of instructional personnel. The shop foreman is indispensable in the factory. The nurse educator must be considered in the same light. She should not be hindered by administrative or clerical work. Her efforts should be rewarded by ample salaries and recognition. Non-nurse instructors should be used as much as possible. Schools might pool personnel. Married nurses could work on a part-time teaching basis. Senior Cadets may act as assistants to nursing arts and clinical instructors.

All-expense scholarships in nurse education courses at colleges and universities have been made available through Bolton Act funds. Nursing schools have been urged by the Division of Nurse Education, U. S. Public Health Service, administrator of

the Corps program, to choose graduates to study for advanced positions and return to the "home" school to teach.

It is apparent, therefore, that all of these bottlenecks on the production front can be solved. The goal can be reached.

Great progress has been made in the program since the appropriation became available on July 16. Rules under which the Bolton Act is administered were formulated by an Advisory Committee, meeting with Dr. Thomas Parran, Surgeon General, U. S. Public Health Service. Represented on this committee were hospitals, nursing schools, universities; medical, administrative, and nursing professions.

The program has been publicized widely in all media of expression. Great credit is due the State Boards of Nurse Examiners for their work in liberalizing admission requirements, aiding in acceleration programs, recruiting students, and in placement of Senior Cadets. Coöperation in these problems has also been given by state and local nursing councils.

Success at the outset of the program has been realized. Now we must look to the future. There is more work to be done before the nurse shortage problem is solved. Continued coöperation by all professional groups is necessary to the success of the program. We cannot afford to fail.

A PROPOSED VITAL RECORDS ACT (S. 1096)

THIS bill, introduced in May, 1943, brings to focus a long and detailed discussion of vital records and statistics. In effect, it provides for transfer of the functions of the Division of Vital Statistics, Bureau of the Census, to the U. S. Public Health Service, and for expansion of these functions. The objectives of the bill are stated as being "for the purpose of coördinating the vital records and vital statistics offices of the State into a coöperative vital records system, including improvement of the registration procedures of such States for the purpose of guaranteeing complete and accurate registration, preservation, and availability of certificates and related records of births, deaths, marriages, divorces, legal separations, annulments, changes of name, adoptions, and legitimations within the United States." It would create, in the Public Health Service, a "Bureau of Vital Records which shall be under the immediate supervision of an Assistant Surgeon General." Very wisely the bill specifically provides that "Nothing contained in this Act shall be construed to modify or supersede in any way the powers, duties, and responsibilities of the various States for the registration of vital statistics."

A full discussion of the background of this proposed legislation can be found in a Message from the President, published as *House Document 242, 78th Congress, 1st Session*. This document, incidentally, is an excellent text on vital records and among other things contains the Report of the Commission on Vital Records, Office of Defense Health and Welfare Services, and the Report of the Vital Records Committee of the Association of State and Territorial Health Officers. Here appears, too, a Report of the Bureau of the Budget Relating to Vital Records and Vital Statistics. All these emphasize the desirability of focusing federal activities in vital records and statistics into a single agency, the need for strengthening and coördinating federal, state, and local activities in this field, and the necessity of enlarging their scope.

The bill in question is designed to do these things, and there appears not to be that type of opposition which was encountered when the Committee on Public

Health Organization, White House Conference on Child Care and Protection, called by President Hoover, recommended in its majority report that certain health activities, scattered in the federal government, be transferred to the Public Health Service. Some of those recommendations created such violent emotion and opposition that Mr. Hoover is to be pardoned for indicating that he was sorry he ever raised the question. Since then the Public Health Service has itself been lifted out of its ancient but anomalous position in the Treasury Department and is now a part of the Federal Security Agency. There it continues its excellent work but we suspect that at times its more grizzled veterans must wonder about some of the strange fellows with whom they are now bedded down.

Even though there is general concurrence that the objectives of S. 1096 are sound, there are certain elements of the bill that need careful scrutiny and, we feel, revision. For example, while the functions of the Division of Vital Statistics of the Bureau of the Census would be transferred to the Public Health Service, the direction of the new Bureau of Vital Records in that Service would be under an Assistant Surgeon General rather than the Surgeon General, thus: "The Assistant Surgeon General [not the Surgeon General] is authorized," "the Assistant Surgeon General shall compile," "the Assistant Surgeon General shall provide . . ." Occasionally, there is reference to "approval of the Surgeon General" but this relates essentially to fiscal procedures. Such tricky tongue-in-the-cheek legislative expressions will tend to defeat what the bill states is its purpose, for organization is jeopardized and administrative confusion assured whenever a subordinate has authority and responsibility neither delegated to him by his chief nor possessed by that chief. If the Public Health Service is to be responsible for federal activities in vital records and statistics, then it is not only desirable but essential that full authority for this activity be vested in the Surgeon General and not in a subordinate. The present bill's ambiguity in expressing this intent constitutes what, in less refined circles, might be designated as double-talk.

Another questionable feature is that the bill would create a "Bureau of Vital Records" in the Public Health Service. It is to be remembered that the principal administrative units of the Public Health Service are *Divisions*. It is difficult to appreciate the necessity for making this new activity a *Bureau*, which administratively is of higher caliber than a Division. Other important services function satisfactorily and on a par with each other as Divisions, and while the Public Health Service might in future profit by reorganization of its structure, there seems no good reason why this new activity should administratively dwarf others to the detriment of the whole. Granted that Vital Records and Statistics are important, so are the Divisions of Scientific Research and States Relations, and Venereal Disease Control.

One must commend this attempt to improve federal activities in vital records and statistics, and must approve an effort to place these functions, administratively, under the principal health agency of that government. One cannot, however, look with equanimity on legislation which by its very language promises deformity of organization and difficulties in administration. If autonomy and isolation of vital records activities are the prime considerations, then keep such activities in the Bureau of the Census; if they are to be placed in the Public Health Service, put them there and have done with it.

Senate Bill 1096 is badly in need of revision.

POLIOMYELITIS REMAINS AN ENIGMA

SOME five years ago Lumsden, who is a hard-bitten epidemiologist of the realistic school, active in field work and incisive in his thinking, presented a paper entitled *Poliomyelitis: Facts and Fallacies*. He opened his paper with this significant quotation: "'What is truth?' asked Pontius Pilate, and did not tarry for an answer." He closed it convinced that not only was the then existing knowledge of poliomyelitis insufficient to permit a statement as to mode of transmission but so meager as to demand continuing exhaustive and intensive research. More recently the same author reviews poliomyelitis in *Texas Reports on Biology and Medicine* and again cautions against authoritarian opinions and deprecates premature conclusions. The articles in question are well worth study and the subject demands serious thought.

Since Lumsden's frank avowal of the limitations of knowledge as to poliomyelitis, no inconsiderable amount of research has been carried on, particularly in relation to the means of transmission of the disease. Reports of the presence of the virus in stools, in sewage, in flies, in a mouse, have stimulated further investigations and speculations; and more and more there is questioning of the correctness of statements as to *Source of Infection* and *Mode of Transmission* of poliomyelitis as set forth in the American Public Health Association's *Control of Communicable Diseases*. Officially, as it were, the source of infection is essentially the nose and throat discharges of infected persons and carriers, "or articles recently soiled therewith"; and as to mode of transmission, it is laid down that "the virus enters the brain by way of the olfactory nerves and bulb when introduced into the nose or nasopharynx of a susceptible person, presumably from a carrier in most instances."

Thus today, with a poliomyelitis season just ending (we hope), the epidemiologist is not much further along than he was two decades ago. Actually, but scant new epidemiological knowledge has been forthcoming. The presence of virus in flies is not truly new, for Rosenau and Brues, and Frost and Anderson more than twenty years ago reported the development of what they believed to be poliomyelitis in monkeys bitten by stable flies. As regards the presence of poliomyelitis virus in human excreta, Kling, *et al.*, in 1912, and Wilbur A. Sawyer, in 1915, reported this. Jungeblut's paper which appeared in the February, 1943, issue of the JOURNAL reported recovery of poliomyelitis virus from a mouse found dead in a home where there had just been a fatal case of poliomyelitis. This is a new note in the search for knowledge but its epidemiological significance cannot be completely interpreted at this time.

Viewed historically, one sees in the present epidemiological gropings in poliomyelitis many characters and gestures similar to those that have occurred in the past, particularly in relation to the yellow fever situation toward the end of the last century. One sees a general tendency to hang on to the respectable-with-age concept of person-to-person transmission, and also there are some non-contagionists. There are found, too, the typical authoritarians who tend to lay down the law with one hand and excommunicate non-believers with the other, and there are the rebels who invite this wrath. One finds in addition the full gamut of old arguments with insistent emphasis on one special feature or another: On constitution and diatheses, on lines of population movement, on the significance of geographic distribution, and the implications of season, temperature, humidity; upon the meaning of attack rates by age, by sex, by race, and rural and urban;

on water, milk, human excreta, beasts and birds and insects. Is there somewhere a Carlos Finlay waiting for a Walter Reed, or a pump-handle waiting for a modern John Snow? '

All in all, the situation strongly suggests a leanness of interpretable facts and a fatness of hard-headed opinions. In such circumstances only the open-minded may claim epidemiologic respectability and they, unlike Pontius Pilate, must tarry for an answer: unashamed to admit ignorance, unawed by authoritarian edicts, persistent and diligent in the search for truth.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

A Manual of Pulmonary Tuberculosis and an Atlas of Thoracic Roentgenology—By *David O. N. Lindberg, M.D., F.A.C.P.* Baltimore: Thomas, 1943. 219 pp. 189 ill. 145 plates. Price, \$6.50.

In this small volume the author has faithfully followed his avowed purpose of presenting "the subject of pulmonary tuberculosis with brevity and sequence, maintaining a closeness to experience in diagnosis, treatment and prevention." The introduction concisely depicts the historical background and enumerates the scientific discoveries and the fundamental methods which favor accurate diagnosis, successful management, and ultimate control.

Part one is devoted to a brief discussion of the essential factors having to do with diagnosis, treatment, and control. This section of the book contains 67 pages and is divided into 5 chapters. These chapters are accompanied by 44 illustrations, including valuable charts and tables. It is surprising how much of the available knowledge concerning the diagnosis and treatment of pulmonary tuberculosis has been crowded into the short space devoted to these subjects, yet the well informed reader may occasionally discover a certain degree of inadequacy because of the enforced brevity. This is particularly true of the chapter on diagnosis.

Roentgenologic technic and interpretation are well presented and in language which may be understood by the reader who is not expert in this field. The chapters on treatment are excellent. They deal briefly but comprehensively with the time tried principles of management, plus the varied methods

of collapse therapy. Finally, the brief chapter on control is logical, sound, and impressive.

Part two contains an Atlas made up of 145 reproductions of well chosen roentgenograms showing pulmonary tuberculosis in its various forms and many non-tuberculous pulmonary conditions. Each illustration is accompanied by a descriptive legend which is distinctly informative and authoritative, thus affording effective data for differential diagnosis. This Atlas alone constitutes a valuable contribution to our knowledge of pulmonary pathology.

The condensed information contained in this small manual should be made available to every medical student and every practising physician.

LEWIS J. MOORMAN

The Kenny Concept of Infantile Paralysis and Its Treatment—By *John A. Pohl, M.D., in collaboration with Sister Elizabeth Kenny. With a foreword by Frank R. Ober, M.D.* Minneapolis: Bruce Publishing Co., 1943. 368 pp. 114 ill. Price, \$5.00.

This book offers for the first time a comprehensive description of the conception and physical treatment of infantile paralysis as evolved by Sister Kenny and her American coworkers.

The main theme of the volume is presented in three parts: the acute stage, the convalescent stage, and the chronic stage. The first chapter in Part I deals with the symptoms of the acute stage under the Kenny concept: muscle spasm, mental alienation (more understandably described as nerve-muscle dissociation); incoördination of muscle action, and muscle weakness and paralysis. The other chapters in this

part include: clinical condition, nursing care, treatment of muscle spasm (preparation and application of hot fomentations), the respiratory system, and muscle stimulation.

The chapters in Part II are: the neuromuscular system (introduction to reëducation), muscle function, classification, type, action and synchronization of muscles, principles of treatment, practical considerations in the restoration of function in all parts of the body, balneotherapy, and the treated patient.

The very brief Part III deals with the rôle of orthopedic surgery and artificial supports in the chronic stage. A commentary by Dr. Miland E. Knapp, Professor of Physical Therapy at the University of Minnesota, concludes the volume. Everybody agrees that Miss Kenny deserves great credit for her original ideas in the conception and treatment of the acute stage of infantile paralysis. These ideas only evolved gradually, as shown by the fact that in her first book, published in Australia in 1937, nothing is said about muscle spasm or hot fomentations. The chief progress in this volume over those previously published is the absence of the large amount of controversy and argumentation which marred Miss Kenny's earlier writings, also the evident endeavor to present controversial issues and points of technic with clarity. Many illustrations add to the practical value of this timely volume which will be studied with equal advantage by physicians and physical therapy technicians, as by all those interested in the care of the victims of infantile paralysis.

RICHARD KOVÁCS

Review of Ethics for Nurses—
By Charlotte A. Aikens. (5th ed.)
Philadelphia: Saunders, 1943. 378 pp.
Price, \$2.50.

This readable 5th edition has as its

chief purpose the aiding of "teachers and students in the study of conduct and duty" as they relate "to nursing and nursing life." The text is designed primarily for the entering student. It aims to stress the importance of careful study of ethical principles and of the "drilling and disciplining of the woman inside the nurse." It emphasizes character as the *sine qua non* of a nurse. It presents in detail myriad carefully selected problems—situations which have troubled students. Frequently the author indicates solutions to these problems. Frequently, also, unanswered questions are designed to stimulate the student's consideration of all sides of problems.

The book consists of three units: (1) Orientation, Some Guiding Principles, which should help to orient the entering student to nursing, (2) Problems of Personal and Professional Conduct, with which the student may have to cope, and (3) Professional Obligations and Adjustments, which may face the graduate nurse.

In addition, questions for discussion or review follow each chapter. Several new chapters have been added, including the opening one on the basic principles of ethics. Many chapters have been expanded or rewritten, while new emphasis has been given the entire book. Suggestions to instructors on methods of teaching and the general handling of the course have been added in an appendix.

Questions which might be raised are:

1. Does the detailed presentation of the many problems help the student most effectively to develop a desirable "pattern for living" or should more emphasis be placed upon the development by the student of a philosophy within which her thought and conduct may be based primarily upon principles?

2. Should material be included which is studied in detail in other courses, as, for example, that in the chapter on "The Evolution of Nursing"?

3. Are the entering students able to ap-

preciate unit 3 which deals with graduate nurse obligations?

4. Would more specific sources of references add to the book's value?

5. Would "school of nursing" be preferred to "training school"?

One cannot read this text without deep appreciation of the author's fine sincerity and broad experience.

KATHARINE J. DENSFORD

Food for People—By Margaret G. Reid. New York: Wiley, 1943. 653 pp. Price, \$4.00.

Food for People opens with a consideration of food in the national economy and provides a clear picture of the present food situation in this country. It discusses food production, processing and preparation, with special reference to changes in methods and their bearing on nutrition and social control. In addition, food consumption, its status and factors affecting it, such as food preferences, food habits, nutrition education, food prices and advertising, are discussed at length.

Here is a well documented, concise, though broad in scope, contribution. It combines the subjects of economics and nutrition so that the movement of foods from production to consumption is discussed in relation to nutritional standards.

The author attempts to measure food consumption in terms of social welfare rather than in statistical trends and dollars and cents value.

However, there are those who will not agree with the sections relating to legislative and social policies. For instance, those who are cognizant of the practical problems underlying subsidies will not share Miss Reid's enthusiasm for this method of solving production and consumption problems. There are many of the measures which she presents that are still new enough and disputed enough to have statements partisan to both sides. There are

some measures that have already been shown to be impractical. Even though the author has presented an interesting treatment of these matters, she interprets many of them in the light of personal beliefs and prejudices.

This is an example of how quickly a book can become out-of-date. Many government offices mentioned, such as the Office of Defense Health and Welfare Services, Civilian Conservation Corps, Works Progress Administration, and Surplus Marketing Administration, are no longer in existence. To ration or not to ration is no longer a question but an actuality.

All told, this book is an authoritative contribution to a growing body of literature on food trends as related to national nutritional adequacy.

MARIETTA EICHELBERGER

Kaiser Wakes the Doctors—By Paul de Kruif, Ph.D. New York: Harcourt, Brace, 1943. 158 pp. Price, \$2.00.

Kaiser wakes the doctors in the best de Kruifian manner. The author is the alarm clock. Some will find his tone raucous, others a clarion call, for in this volume de Kruif employs that flair for writing and those journalistic technics by which in the past he has simultaneously aroused public interest and lifted scientific eyebrows.

Essentially, this volume tells the story of Mr. Kaiser's determination to provide good medical care for his employees. The fact that such care produces more efficient workmen is only incidental in this great builder's vision. He has a deep and abiding conviction that ordinary human beings should not be excluded from the best medical care merely because they have not sufficient funds to pay what such care costs under the present system of medical practice. Dr. Garfield is his medical director and he, on the basis of previous experiences, builds up a voluntary prepaid insurance

scheme whereby Mr. Kaiser's employees are provided a high grade medical service on the group practice basis. The fifty cents a week from each workman plus fees from compensation cases provide income sufficient, in an amazingly short time, to pay for laboratory work, x-rays, specialists, medical care, equipment, clinics, hospitals, and everything else.

The book is easy to read; and one is so strongly caught in the surging tide of great accomplishments that, for the time being at least, he tends to cheer Mr. Kaiser and his medical director and their shining goal just as he would cheer for Galahad and the Holy Grail, or for Horatio Alger, Jr. The author creates this state of mind in his readers by dramatizing ordinarily humdrum situations, by creating hero rôles for his characters, and, to no small extent, by his own Gargantuan enthusiasm. In the course of his narrative de Kruif attempts both to show and show up what he considers to be the invisible and deterring hand of a medical hierarchy, balances democratic though fumbling freedom to choose one's physician against impersonal but effective medical teamwork and finds the former wanting, indicates disapproval of government managed medical care and hopes for an extension of the Kaiser medical service system throughout industry, into rural areas, and for the country as a whole. There is a final recommendation that there be created a government Medical Loan Agency which would guarantee to "local bankers 50 per cent of any losses which might come as a result of the banks' willingness to finance these new Mayo Clinics for the common man."

Those engaged in public health work ought to read this story. Although in hyperbole, it recounts a fine undertaking from which much that is sound may be learned. Probably the book will be received enthusiastically and un-

critically by the reading public; certainly it will be gagged on as a bitter dose by those who believe that satisfactory medical care must be divided into as many administrative units as there are physicians practising.

H. S. MUSTARD

Whooping Cough—By *Joseph H. Lapin*. Springfield, Ill.: Thomas, 1943. 273 pp. Price, \$4.50.

The growing number of reports on whooping cough contain so many conflicting views and observations that a thorough survey and appraisal of the literature by one experienced in this field is needed. Dr. Lapin essays this formidable task in a book covering clinical, laboratory, public health and experimental aspects of this disease. The bibliography is desirably comprehensive but in the opinion of the reviewer the author has erred in attempting to mention in some detail in the text nearly all of the articles he has read.

An impression of insufficient exercise of critical appraisal is conveyed by devotion of space to publications amounting only to expression of unsupported opinion or inadequately controlled observations. In commenting on Table 21, age selection is noted as a factor depreciating the apparent superiority of convalescent to hyperimmune serum, but lack of statistical significance is overlooked. The physician or health officer will not find the difficult task of selecting a potent vaccine made easier by the author's broad conclusion that the efficacy of pertussis vaccines, washed or unwashed, with or without the toxic factor, is now proved quite adequately.

Dr. Lapin recommends exclusion of contacts from school for at least two weeks from last exposure, unless examined daily by a physician and cough plates taken. In support of this recommendation he argues that due to fail-

ure to exclude contacts from school, New York City has the highest case fatality rate among 13 cities over 500,000 population, although the source article makes it clear that the high rate is due to poor case reporting and New York's mortality rate ranks fourth lowest. Quarantine of cases, with placard, for 4 weeks, except where the physician may choose to allow the patient abroad with an armband, seems neither practicable nor justifiable.

This book should serve best as a convenient means of locating literature on the subject of whooping cough.

P. A. LEMBCKE

Health of Our Nation Series—By Brownell and Williams. New York: American Book Company, 1943.

1. Well and Happy. 156 pp. \$.76.
 2. Clean and Strong. 180 pp. \$.80.
 3. Fit and Ready. 243 pp. \$.84.
 4. Safe and Sound. 279 pp. \$.88.
 5. Hale and Hearty. 303 pp. \$.92.
 6. Active and Alert. 311 pp. \$.96.
 7. Living and Doing. 346 pp. \$1.00.
 8. Adventures in Growing Up—Brownell, Williams, Conrad, Evans, Kaplan, Pinckney and Ruef. 488 pp. \$1.60.
 9. Health Problems—How to Solve Them—Brownell, Williams and Hughes. 317 pp. \$1.52.
 10. Being Alive—Human Structure and Functions—Brownell, Williams, Hughes. 430 pp. \$1.60.
- Youth Faces Maturity. 30 pp. \$.20.

The Health of Our Nation Series consists of 10 volumes—7 for use as textbooks in 7 grades of elementary school, and 3 on a more advanced level.

The subject matter of these books presents comprehensively all phases of the health, growth, and personality of the child. A survey of the tables of contents reveals chapters on cleanliness, nutrition, safety, medical services, physical training, prevention of dis-

eases, and personality development. It is evident that the authors assume a knowledge of health, preventive medicine, and physiology among teachers that is rare.

The books show evidence of thorough planning. They are well graded in difficulty. The early books are planned to serve as readers. Beginning with the 4th book, a transition toward the textbook rather than the story book approach is evident. Each book expands the subjects of previous volumes and then includes one or two new topics. The authors effectively apply their own concept—that is, that growth includes a gradual expansion of control over self and environment. The volume *Being Alive* does not fit into the pattern with the other books. It is a textbook of anatomy and physiology and must be considered separately. In our opinion, the presentation of such technical subject matter requires further elaboration for the average high school student.

The series shows little recognition of organized public health as a means of protecting the community against disease. The milk inspector works for some mysterious unnamed agency. The health officer is a man who comes out of nowhere to tack up a quarantine placard. The public health physician is not mentioned.

An undue emphasis on physical training as a means of obtaining good health permeates the entire series. Fresh air, exercise, games, competitive sports, and good posture are offered as panaceas. There are several medical inaccuracies, and the books present concepts no longer generally accepted by the medical profession. For instance, the procedure of active and passive immunization against scarlet fever, as suggested by the books, is no longer considered good medical practice.

Despite these rather trivial objec-

tions, the *Health of Our Nation Series* is a splendid contribution to the teaching of health. The authors effectively motivate healthful living, giving the child concrete aims and objectives.

ELEANOR SACHS and
BENJAMIN SACHS

Memoir of Walter Reed—By *Albert E. Truby, Brig. Gen. U. S. Army Ret.* New York: Hoeber, 1943. 239 pp. Price, \$3.50.

It is indeed fortunate that this work has appeared before the firsthand information it contains has become unavailable. Few are still living who know intimately the details of this phase of the life of Walter Reed, and none knew this time and work better than Truby. He has been assisted by several others who were also present at the time. The result is a most interesting and valuable picture of the events that led up to one of the greatest medical discoveries of all time, i.e., the method of the spread of yellow fever, and the almost complete control of the disease that has resulted from this discovery.

As this reviewer sees it, Truby has cleared up a number of interesting details that heretofore were not clear. Many points were lacking in the account about which many of us have wondered. And although both Reed and Carroll were the reviewer's teachers at the Army Medical School some three years before the events mentioned and, though he followed their work at the time, and read everything available since, it took this book to reveal to him what was lacking. It is probable that many others therefore, will likewise appreciate this very interesting account by one who was actually present and intimately concerned with these events.

The book is clearly and interestingly written, gives an excellent picture of the time and place, and is practically

free from typographical errors. The type is easy on the eyes and the illustrations and drawings are very satisfactory. It should be available in every library, certainly every medical library. It has definite historic value.

COL. GEORGE A. SKINNER

Edelmann's Textbook of Meat Hygiene—By *J. R. Mohler and A. Eichhorn.* (8th ed.) Philadelphia: Lea & Febiger, 1943. 468 pp. Price, \$5.50.

The story of federal meat inspection is that of a national agency taking over a limited portion of the field of meat control, carrying on a technically excellent job but in almost complete isolation from other federal, state, or local agencies in the related public health and food control fields. As a mark of the thoroughness of this isolation, the book before us, largely the work of the two leading officials in the federal meat inspection bureau, makes no single reference whatsoever to the existence of state or local meat inspections, nor gives any recognition to the fact that 35 per cent of the beef cattle, 40 per cent of the calves and hogs, and 20 per cent of sheep and lambs slaughtered for food in this country do not receive federal inspection.

This may also have led to the self confident attitude as shown by the following paragraph in the author's preface to this eighth edition of the book (page 3):

Through the splendid organization of Federal Meat Inspection in the United States, the incidence of harmful results from consumption of meat and meat food products has been reduced to a minimum and it behooves those in charge of this important hygienic procedure to continue the excellent work which has been recognized as a model for guarding the public health from disease resulting from the ingestion of contaminated meats and meat food products. The limited number of such cases which have been traced to meats and meat food products could invariably be attributed to exposures after

the products have left the custody of the controlled establishments and therefore must be considered the result of careless handling in the subsequent processing, storing, and culinary preparation.

This would seem to ignore too readily the frequent and increasing number of food poisoning outbreaks, largely staphylococcus poisonings, in which meat (cured hams, tongues, etc.) has been involved. Nowhere in the volume have I found mention of any inadequacy in the Federal Meat Inspection Service.

From a public health standpoint, the volume fails to present a full picture of the highly important trichinosis problem. Not one word is given of the extensive studies on trichinosis by Dr. Maurice C. Hall and his coworkers of the U. S. Public Health Service. The most recent data on occurrences of trichinosis given in the book go back to 1913. Again the authors would lead you to assume that, at least as to federally inspected meat, there is no trichinosis hazard, for example, their comments on (page 283): "Instructions have been issued in connection with Federal meat inspection for the purpose of avoiding any possible danger from the ingestion of trichinous meat." This statement fails to make clear that these instructions, which are requirements for treatment (curing, refrigeration, heating) apply only to pork products *classed as commonly eaten raw*—hams, pork butts, sausages, and that pork and pork products not recognized as commonly eaten raw may be trichinous, and known to be such, yet will be stamped as inspected and passed. That little or no reliance can be placed on the warning that thorough cooking of pork must be carried out at the time of preparation, is too well shown by the numbers of trichinosis infections now being encountered.

These few critical observations on this Eighth Edition of *Textbook of*

Meat Hygiene by Edelmann, Mohler, and Eichhorn are not in any way to be taken as an indication that an unsatisfactory treatise on the subject has been presented—quite the other way. This book is a finely done and outstanding work and has long been given a most authoritative position in its field. The book contains well written and illustrated chapters on Morphology and Chemistry of Tissues and Organs of Food Animals, on Diseases of Food Producing Animals. It is especially thorough and complete in presenting the history, procedures, practices, regulations of the Federal Meat Inspection Service. Full illustrated descriptions are given of the operations carried on in abattoirs and meat processing plants under the federal control. I can think of no veterinarian or other worker active in meat inspection who would not need to have this volume within his ready reach.

SOL PINCUS

Do You Want to Be a Nurse?—
By Dorothy Sutherland. Garden City: Doubleday, Doran, 1942. 186 pp. Price, \$2.00.

For girls in high school and college who wish for more details about nursing as a career than they can read in the free pamphlets available from the Nursing Information Bureau (1790 Broadway, New York, N. Y.), Miss Sutherland's small book *Do You Want to Be a Nurse?* is an informative guide. Unfortunately, nursing in wartime is subject to change overnight and already some of the statements in this book need modification. The author gives in full, however, the names and addresses of agencies where up-to-the-minute vocational guidance can be obtained.

One might gain the impression after reading Miss Sutherland's description of what it takes to make a successful nurse, that only super-women need apply. Such an approach may be discouraging to the average young woman

who cannot realize that she may develop the essential qualities only after three years of experience in caring for the sick. On the whole, however, the profession is presented attractively and fairly and the thumbnail sketches of actual work now being performed by nurses will open wider horizons to prospective nurses than they have probably envisioned in the past.

DOROTHY DEMING

The Conquest of Epidemic Disease—By *Charles-Edward Amory Winslow*. Princeton: Princeton University Press, 1943. 411 pp. Price, \$4.50.

This book is more than a compendium of data and references from the Old Testament theory of pestilence as a punishment for sin, through the days of demons, miasms, and germs, down to the streamlined concepts of the virus diseases and the new views concerning aerial dissemination of infection. It is an interesting and highly instructive story, rich with the author's interpretations of the values of each stage of the historical development of knowledge regarding the modes and channels of disease spread.

From a consideration of Hippocratic thought with its visualization of a universe of natural law, but without significant reference to disease communicability, the reader progresses to the primitive concepts of contagion. The recognition of the relation of human plague to diseases of rodents soon suggested an implication of contagion. Galen had recognized that rabies is caused by the bite of a mad dog and Bernard Gordon in the 13th century had contributed his famous list of the eight diseases which were contagious, but it remained for the Black Death, which became pandemic in the middle of the 14th century, to teach beyond any peradventure the communicability of disease.

The chapter on Fracastorius illustrates the instructive way in which the author has discussed the then prevailing views of the causes of disease and proceeds to a critical analysis of a new contribution. The essay on *Contagion* is outlined by chapters with a generous seasoning of comment which makes the book invaluable to the student of public health. In fact, not only the epidemiologist and public health administrator but every practitioner of preventive medicine will enjoy and derive great value from a reading of this book.

It was Fracastorius in the early 16th century who presented the fundamental classification of three different types of contagion—those which infect by direct contact only, those which may also spread by fomes, and those which may infect at a distance. Paying tribute to Sydenham as a great clinician, the English Hippocrates, the author states that "his almost complete neglect of contagion as a practical factor in the spread of epidemic disease and his major stress upon the metaphysical factor of epidemic constitution held back epidemiological progress for two hundred years."

The story of yellow fever in our colonial days is interestingly told by the work of Benjamin Rush and Noah Webster who still adhered to the doctrine that one disease could be transformed into another. "The nineteenth century Filth Theory of Disease was a relatively precise and scientific form of the old doctrine of miasms. It was backed up by statistical and epidemiological evidence; and it actually accomplished results in the practical control of epidemic disease."

The strength of the miasmatic theory was overthrown before the days of Pasteur by the three pioneer epidemiologists, Panum, Budd, and Snow. Their studies on measles, typhoid fever, and cholera are well known to every

student, but Winslow takes the reader in behind the scenes and shows how these healthmen demonstrated the basic facts with regard to the spread of these diseases.

There is a fine chapter on Pasteur, with proportionate credit to Plenciz, Henle, Lister, and Koch for the contributions that these men and their associates made to the newer knowledge. In discussing the importance of the human carrier to disease dissemination, the work of Koch with cholera is recognized; Park and Beebe with diphtheria; Reed, Vaughan, and Shakespeare with typhoid; and later work of other pioneers with meningitis and poliomyelitis. To Theobald Smith goes major credit for solving the puzzling problem of the insect host. The work of Manson with filariasis, Bruce with the tsetse-fly, Ross and Laveran with malaria, Reed and his associates with yellow fever, the English Plague Commission, is not overlooked. Quite appropriately the book closes with a recital of the contributions of Chapin, that dean of American public health administrators, who had the courage to practise the principles established by the research investigator and laboratory worker.

In the words of the author "we are too prone to honor (or dishonor) the great men of the past without ever reading them to see what they really said." Here is our opportunity to know these great men through the laborious readings and studies of a great teacher, an epidemiologist, laboratorian, and health educator, a leader among the healthmen of our age. HENRY F. VAUGHAN

Communicable Diseases for Nurses—By Bower and Pilant. (5th ed.) New York: Saunders, 1943. 562 pp. Price, \$3.00.

The list of infectious diseases treated in this fifth edition is exhaustive. Practical, specific suggestions are given for

the nursing care of each disease and the relation of good nursing to the prevention of complications is consistently stressed. The excellent colored photographs which illustrate the various eruptions and changes in throat conditions are invaluable teaching aids since it is seldom possible for a student nurse to be in the communicable disease department in more than one season.

The description of medical aseptic technic is clear, well illustrated, and contains many practical suggestions, but may leave the reader with the impression that there is only one *right* way to set up an isolation technic. If student nurses are going to be able, as graduates, to direct the care of communicable diseases in homes, on open wards, in clinics or wherever adaptations are needed, their thinking must be directed toward the *principles* upon which such technics are based. The chapter on the care of communicable disease in the home would be more valuable if the emphasis were placed upon the nursing care of the patient and the instructions to be given the mother in that regard rather than upon the fine details of technic. Too often the nurse tries to impose a rigid technic designed for the hospital with its clearly differentiated "clean" and "contaminated" areas, and forgets that the patients' completed restoration to health is the most important thing.

Many supervisors of communicable disease departments will disagree with the suggestion found on page 46 that it is necessary, even desirable, to have a "treatment nurse" pour the medicines and prepare the hypodermics for the nurse in the unit to administer.

This edition introduces a set of questions at the close of each chapter. They are quite elementary, sometimes self-evident, and can be answered by direct quotation from the facts stated in the chapter. They would be much more valuable if they were "problem"

questions, the solution of which depended upon the student's ability to understand and apply the facts presented.

The book provides excellent reference material and is recommended for every communicable disease library.

IDA MACDONALD

Behind the Sulfa Drugs. *A Short History of Chemotherapy*—By Iago Galdston, M.D. New York: Appleton-Century, 1943. 174 pp. Price, \$2.00.

This book is more accurately described by the subtitle than by the title, for it summarizes the course of events in the entire field of chemotherapy. It is extraordinarily interesting.

One's attention is caught on the first page by a discussion of the precise meaning of the word "Chemotherapy" and of what distinguishes it from the older "Iatrochemistry." There follow brief but vivid sketches of Paracelsus and Boyle, of the pioneers in the coal industry and William Henry (Mauve) Perkin. Pasteur and Koch are introduced for the part they played in defining the objective. But the main body of the book is devoted to an analysis of the achievements of Paul Ehrlich. The account is necessarily abridged, yet the image it presents of the many facets of this brilliant mind is three dimensional for all its compactness. In the last two and one-half chapters the story of the sulfonamides themselves is dealt with—somewhat sketchily, considering the title.

Two errors call for comment. Poliomyelitis and influenza are spoken of as bacterial diseases and sulfanilamide is twice described as a dye. The latter mistake is annoying to the present reviewer who believes that it was because sulfanilamide is *not* a dye that it lay unrecognized for twenty-five years. But these lapses, while irritating to the specialist, will do the general public no harm, nor do they detract from the interest which the book as a whole will

have for the scientist who wants to know how chemotherapy came about.

ELEANOR A. BLISS

Chemical-Technical Dictionary—By A. W. Mayer. (*German-English-French-Russian.*) (1st American ed.) Translation under the direction of Prof. B. N. Menshutkin and Prof. M. A. Bloch. Brooklyn: Chemical Publishing Co., 1942. 872 pp. Price, \$8.00.

The reviewer is at a loss to see the need for the publication here of a four-language dictionary with English instead of American spelling, particularly in view of the existing excellent six-language dictionaries available.

The paper used is very poor for a book intended for continuous and hard use; the printing is even poorer, having obviously been done from old type or plates. There are many broken letters which cannot be read, even with a magnifying glass.

Twenty-five German words, strictly of chemical import were taken at random from two other German-English dictionaries. Of these seven were absent from this alleged new work which shows internal evidence of a hastily-done, old job. Biochemical terms are conspicuously absent. The purchase of this book cannot be recommended.

D. D. BEROLZHEIMER

Health and Physical Fitness—By I. H. Goldberger and Grace T. Hallock. New York: Ginn, 1943. 596 pp. Price, \$1.92.

Health and Physical Fitness is a lively new, highly interesting book.

To one grown up in health education, it is most refreshing, expressing many of the basic technics advocated by qualified workers in this field.

The book was written for today with wartime emphasis throughout. The following examples will indicate that the subject material is recent: The High School Victory Corps Physical Fitness

Program, food rationing and food requirements, absenteeism in industry, use of blood plasma, nursery school care of children of working mothers, civilian defense and Red Cross activities, chemical warfare, communicable disease control, mental health and war fears, tuberculosis control, a balanced program of work, exercise, recreation, rest and sleep during wartime.

A great wealth of health education material is packed into one small volume, arranged in easy reading style, that should be a delight to the busy reader.

For more serious use the book is especially adapted for classroom teaching of high school pupils and youth groups. It answers many of the health and personal hygiene questions of youth. It is arranged in units of instruction with attractive captions and at the end of each unit there are stimulating questions—methods of testing one's health knowledge, and suggestions for further research.

At this time the book can be especially useful in the High School Victory Corps Physical Fitness Program. The volume provides in sound scientific and interesting fashion much of the health education material one would like to crowd into the last opportunity of instructing boys and girls who are leaving schools and are going into war service or to jobs in essential industries.

The book is illustrated throughout with numerous excellent photographs suited to the subject matter and having just the proper psychological effect. There are also many unique diagrams not seen by the reviewer in any previous books.

CARL A. WILZBACH

Oral Tests in Public Personnel Selection—A Report Submitted to the Civil Service Assembly—By the Committee on Oral Tests in Public Personnel Selection, Samuel H. Ord-

way, Jr., Chairman. Chicago: Civil Service Assembly of the United States and Canada, 1943. 174 pp.

The oral test as a means of arriving at a competitive evaluation of the "personal traits, characteristics, capacities, and behavior patterns that are believed to indicate the probability of success on the job" has probably come to be considered the most indispensable tool of public personnel selection. As such, it cannot be too often or too intensively scrutinized and appraised. The Civil Service Assembly in the most recent of a series of reports dealing with public personnel administration has done a thoroughly conscientious job of underlining the shortcomings inherent in an unintelligent application of the technic, and has presented an instructive analysis of the steps which must be taken to transform what has often been an arbitrary, inequitable, and inefficient measure into what can be a controlled, legally defensible, and fruitful procedure.

LILLIAN DICK LONG

The Examination of Waters and Water Supplies—By E. V. Suckling. (5th ed.) Philadelphia: Blakiston, 1943. 849 pp. Price, \$12.00.

This volume is the fifth edition of the best known compendium on water examination. The author has accomplished a difficult job in a manner which does credit to his distinguished predecessors, Dr. Thresh and Dr. Beale. This book is far more than its title indicates. It is a discussion of the chemical and biologic ingredients of waters from many sources, the interpretation and the methods of chemical and biologic analyses and their limitations. The emphasis is on analyses for sanitary purposes.

Methods for chemical analysis correspond closely to those in use in this country. As described they can be used only by a trained chemist. This

is entirely to the credit of the author. Too many American laboratory manuals are written with the hope that the office boy can replace the graduate chemist. The determination of free chlorine is described too briefly in view of the difficulties involved.

Bacteriologic methods differ from those in use in this country mainly because MacConkey lactose broth and agar are still the preferred media in English laboratories. Much valuable data on the differentiation of coliform bacteria are included. The author recommends "Bact. coli" as the best indicator of fecal pollution. For practical tests, the appearance of characteristic colonies on MacConkey agar after gas formation in lactose broth, is regarded as sufficient, but further differential tests are strongly

urged. The presence or absence of fecal types of coliform organisms in 100 cc. of water is the criterion of choice, with the usual reservations concerning the significance of the other coliform bacteria.

A considerable section is devoted to the purification of water in all its phases. An interesting section gives detailed mineral analyses of waters from various geologic sources.

There is evident confusion between the laboratory guide *Standard Methods for the Examination of Water and Sewage*, published by the A.P.H.A. and the A.W.W.A., and the U. S. Public Health Service standards of purity for common carriers but such confusion exists also in this country.

JOHN F. NORTON

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Boom in Baby Business—Just what the anticipated 1943 birth rate of 24 per 1,000 will mean in terms of limited medical and nursing services is dramatized in a graph showing the cumulation of gains in births during the last decade.

ANON. A Dividend of Two Million Babies in Ten Years. *Stat. Bull. (Met. Life Ins. Co.)*. 24, 8:4 (Aug.), 1943.

108,000 M.D.'s : 120.8 Millions :: 1:1,118.5—From the O.W.I. comes this comprehensive report on health and doctor shortage, the data originating in the Public Health Service, War Manpower Commission, and the Federal Works Agency.

ANON. Doctor Shortage and Civilian Health in Wartime. *J.A.M.A.* 123, 4:214 (Sept. 25), 1943.

Health Barometer of Germany's Large Cities B. B. (Before Bombing)—Infant death rate increased to 66 in 1942, and deaths of children under 5 rose sharply, but adolescents' rates rose more sharply than any other group. Tuberculosis death rates in 1942 were 24 per cent higher than in 1939. Suicides, too, have increased during the war years. Birth rate—12.7—is down from 17.3 in 1940.

ANON. The Death Rate in Germany. *Science*. 98, 2536:126 (Aug. 6), 1943.

Babies' Sore Eyes Are Cured—Items on medical treatment are not supposed to be included in these annotations, but this one seems to be of sufficient interest to public health to warrant mention here. Infants with gonorrheal ophthalmia treated with sulfonamide drugs by mouth were cured quickly, without complications.

BLUMBERG, M. L., and GLEICH, M. The Simplified Treatment of Gonococccic Ophthalmia Neonatorum With Chemotherapy. *J.A.M.A.* 123, 3:132 (Sept. 18), 1943.

Physical Wrecks, Unlimited—If this sampling is at all typical of our young American men, then the state of their physical incompetence is nothing short of appalling, and health and physical educational programs stand convicted of their inadequacy.

CURETON, T. K. The Unfitness of Young Men in Motor Fitness. *J.A.M.A.* 123, 2:70 (Sept. 11), 1943.

Some Good from Very Ill Wind—By the end of this year 25,000 asymptomatic persons will have been discovered and diagnosed as needing hospitalization for tuberculosis. That can be put to the credit of the war which, Heaven knows, has plenty on the debit side of the balance sheet.

DEMPESEY, M. New Cases of Tuberculosis Discovered by Case-Finding Surveys. *Am. Rev. Tuberc.* 48, 1:58 (July), 1943.

Why Does Cancer of the Lungs Increase?—Rapid increases in the death rate of cancer of the respiratory system are in striking contrast to the slowing change in death rates for all forms of cancer. The author explores the possibility of atmospheric pollution as a precipitating cause and can discover no affirmative evidence. He assumes that the causes are too complicated to be discovered by the relatively crude statistical sources now available.

DORN, H. F. The Incidence and Prevalence of Cancer of the Lung. *Pub. Health Rep.* 58, 34:1265 (Aug. 20), 1943.

Preventing Radium Poisoning—If proper precautions are taken, there

need never be any more deaths or injury due to exposure to radium by dial painters and others. You will be interested in the thoroughness with which the precautionary measures must be applied even though there may be no shops utilizing radium in your own bailiwick.

EVANS, R. D., Protection of Radium Dial Workers and Radiologists from Injury by Radium (and) MORRIS, G. E., *et al.* Protection of Radium Dial Painters—Specific Work Habits and Equipment. *J. Indust. Hyg. & Toxicol.* 25, 7:253 (Sept.), 1943.

Odd Facts Department—Twenty years ago some cultures of *Bacillus pestis* were stoppered tight and put away. When subcultured this year, 2 out of each 3 were still viable. Guinea pigs inoculated with some of the cultures died of plague and the organisms were recovered from their blood.

FRANCIS, E. Twenty-Year Survival of Virulent *Bacillus Pestis* Cultures Without Transfer. *Pub. Health Rep.* 58, 37:1378 (Sept. 10), 1943.

Morbidity Rates Mount—Illness rates for employed men and women in 1942 were highest of a decade. The chief incapacitating causes among the men that year were pneumonia, bronchitis, and diarrhea and enteritis. The corresponding causes for the females were diseases of the organs of locomotion, pneumonia, and neurasthenia. Interesting graphs throw some light on these phenomena.

GAFAFER, W. M. Sickness Absenteeism among Male and Female Industrial Workers 1933–1942 Inclusive. *Pub. Health Rep.* 58, 33:1250 (Aug. 13), 1943.

“As Long as It Isn’t a Pill”—American diets are deficient in vitamins, and the American diet is what the war worker eats. Vitamin concentrates fed to war workers increase production, and production is the essence of our national salvation. Ergo, give workers vitamins. Even some of the cons

among the discussers admit that brewer’s yeast might properly be given—as long as it isn’t in “pill” form. As this seems to be breaking-the-rule month for this bibliography, the rule of items from scientific periodicals only is broken to point to a paper in this excellent report which should be in every public health agency’s library.

HAGGARD, H. W. Should War Workers Be Fed Vitamins? *The Nutrition Front. Legislative Document No. 64, 1943.* Report of the New York State Joint Legislative Committee on Nutrition.

Good News for Infant Pin Cushions—Alum-precipitated, combined diphtheria toxoid and pertussis vaccine protected children against both diseases and spared the youngsters some unwelcome injections.

KENDRICK, P. L. A Field Study of Alum-Precipitated Combined Pertussis Vaccine and Diphtheria Toxoid for Active Immunization. *Am. J. Hyg.* 38, 2:193 (Sept.), 1943.

Our Ill-Favored Youth—Among 45,000 draft registrants 18 and 19 years old, 253 per 1,000 were rejected. The table of causes of rejection for white boys and negroes is disheartening but important. It should be noted that the cream of the physical crop had already enlisted or had been enrolled while in college, or had been accepted in defense jobs. Still the record is dreadful.

ROWNTREE, L. G., *et al.* Causes of Rejection and the Incidence of Defects. *J.A.M.A.* 123, 4:182 (Sept. 25), 1943.

It’s Not Just Chills’n’Fever—Recent experiences with malaria have given rise to some new concepts in the prevention and treatment of the disease which you should know about. Atypical malaria complicates the picture. In the same issue of the *Journal* is an official pronouncement on the modern treatment of malaria.

TALBOT, D. R. New Aspects of Malaria. *J.A.M.A.* 123, 4:192 (Sept. 25), 1943.

Sister Kenny Should Worry!—Kenny concepts of muscle involvement in poliomyelitis, although the basis of an excellent type of treatment, are inadequate as a physiologic explanation of the dysfunction present. Proof-of-the-pudding minded health workers will read this excellent paper with a detached open-mindedness. Of Kenny's three descriptive terms, only "incoördination" holds water: but for this the authors suggest, as a substitute, "disordered reciprocal innervation."

WATKINS, A. L., *et al.* Concepts of Muscle Dysfunction in Poliomyelitis. J.A.M.A. 123, 4:188 (Sept. 25), 1943.

A Paper You Should Read—Roughly 25 per cent of our food production will be purchased by the government, yet as much will be left for home consumption as was used before the war. Red meat—believe it or not—is almost as plentiful as for the period 1935–1939: at 124.5 pounds per capita. With better money wages consumption of the protective (and expensive) foods was greatly increased. But, even in this day, a fifth of our population does not receive income enough to purchase the kind of food needed for a good diet. Note of apology: these annotations are not intended to be in the nature of abstracts,

but I couldn't resist a few excerpts from this paper packed with useful information.

WILDER, R. M. Nutritional Requirements in Time of War. New Eng. J. Med. 229, 13:495 (Sept. 23), 1943.

Garbage-Fed Swine Stand Condemned—Among nearly 12,000 post-mortem examinations of diaphragm muscle conducted the country over, 16 per cent were positive for *Trichinella spiralis*. Data are presented in this summary which indicate that superimposed trichina infections occur, that previous infections confer no immunity, and that not all attacks are diagnosed.

WRIGHT, W. H., *et al.* Studies on Trichinosis. Pub. Health Rep. 58, 35:1293 (Aug. 27), 1943.

Toward Better Mental Health—Something about the historical and the present-day activities of the twenty year old mental health program in Massachusetts. The constantly increasing preventive services rendered by the state agency and the heightening public awareness of the need for better mental health facilities are telling straws in the wind.

YERBURY, E. C. A State Mental Hygiene Program. Mental Hygiene. 27, 3:457 (July), 1943.

ASSOCIATION NEWS

OFFICERS, 1943-1944

President, Felix J. Underwood, M.D., Jackson, Miss.

President-Elect, John J. Sippy, M.D., Stockton, Calif.

Vice-Presidents, Jean Gregoire, M.D., Quebec, Canada

Pearl Kendrick, Sc.D., Grand Rapids, Mich.

G. H. de Paula Souza, M.D., Sao Paulo, Brazil

Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.

Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.

Chairman of Executive Board, Abel Wolman, Dr.Eng., Baltimore, Md.

New members of Executive Board:

Hugh R. Leavell, M.D., Louisville, Ky. (1946)

Edward G. McGavran, M.D., Clayton, Mo. (1946)

Sedgwick Memorial Medal for 1943 Awarded to Dr. James Stevens Simmons

Brigadier General James Stevens Simmons, M.C., U. S. A., to whom the Sedgwick Memorial Medal was awarded for 1943, is Chief of the Preventive Medicine Division of the Office of the Surgeon General, U. S. Army, Washington, D. C. General Simmons was

born in North Carolina in 1890. After attending Davidson College and the University of North Carolina he received his medical degree in 1915 from the University of Pennsylvania, followed in 1934 by a Ph.D. degree at George Washington University Medical School, and by the doctorate in public health at Harvard in 1939. Davidson College awarded him an honorary doctorate in science in 1937. Dr. Simmons entered the Medical Corps in July, 1916, serving as Chief of the Laboratory Service at the Base Hospital at Fort Bliss, Tex., and Commanding Officer of the Southern Department Laboratories and Chief of Laboratory Service, Fort Sam Houston, Tex. He organized and commanded the stationary overseas laboratory No. 6 at the Yale Army Laboratory School 1918. He was in charge of laboratory work investigating meningitis carriers 1919, and in that year became Chief of Laboratory Service, Walter Reed Hospital, Washington. He later served in laboratory positions in the Hawaiian Islands and was placed in charge of

James Stevens Simmons

the Department of Bacteriology at the Army Medical, Dental and Veterinary Schools, Washington, where he served from 1924 to 1928, later becoming Director of the Department of Preventive Medicine in the Army Medical, Dental and Veterinary Schools, Washington.

General Simmons has shown special interest among other subjects, in leprosy control and in the encephalitis epidemic in St. Louis. He has been

a member of the National Malaria Committee since 1936. He served on the A.P.H.A. Committee for the Study of the Effectiveness of Typhoid Vaccination. He is a lecturer in preventive medicine at The Johns Hopkins Medical School, and is the Army member of the Division of Medical Sciences, National Research Council. His recently collected bibliography included 98 titles.

MESSAGE FROM THE BRITISH MINISTER OF HEALTH

The Right Honorable Ernest Brown, M.C., M.P., Minister of Health in Great Britain, has sent the following message to the American Public Health Association through Frank A. Calderone, M.D., the Chairman of the War Health Information Committee in connection with the 72nd Annual Meeting of the Association.

"The British Commonwealth of Nations and the United States of America are linked in a common struggle against common enemies. When the forces of evil are defeated, there will be new battles to be fought; and one will be against Disease, that eternal enemy of human happiness, security and welfare. If we are to win the peace, the Battle of Health must be waged with all available resources and on the broadest possible front. We shall still be engaged in a common struggle against common enemies; because disease knows no boundaries, and the public health problems which will follow global warfare cannot be tackled effectively unless they are approached internationally.

"Already there is a large measure of co-operation between the Allies—complete exchange of information, and pooling of resources in drugs and medical equipment, for example. We have had in Britain most valuable personal assistance from leaders of American Medical Science such as Professor

Gordon of Harvard, Professor Sydenstricker, Dr. Meiklejohn, Dr. Wilson and many others. From our side of the Atlantic Ocean, Sir Wilson Jameson, Dr. Macintosh, Professor Burn and the late Dr. Warrington York have paid visits to facilitate co-operation and to tell you all they can about our experience of public health problems under the strains of war, including heavy bombing of civilian populations. International co-operation of this kind must continue and, indeed, expand. I shall look forward to the return of Dr. Dorothy Taylor, the Senior Medical Officer for maternal and child welfare in my Ministry, and to receiving from her a first hand account of your deliberations in which she is taking part this October.

"The pioneering spirit of the Rockefeller Foundation in bringing health to the less fortunate peoples of the earth has been a pointer on the way of social betterment which the British Commonwealth is also following. Even more intensive measures are being taken in the Colonies and Dependencies to improve medical services in the widest sense. I do not need to remind this Conference of the leading place British doctors have taken in the development of the science of Tropical Diseases. A special problem of the present and the future is malaria, and I can assure you that the Governments of our two

peoples have completely interlocked their plans for dealing with this terrible menace.

"The problem of post-war relief of the peoples we shall free from Nazi tyranny are staggering in their magnitude. Already large scale plans are being made by our Governments acting in concert. I see in this a tremendous impetus to international co-operation which will not die away when the immediate crisis is past.

"On the Health Front at home, Britain has learned three big lessons. For the first time, we have a national, planned policy on nutrition; and living as we are on a narrow margin of rations, we have drawn rich dividends from it. I fully believe that after the war none of us is going to lose sight of the benefits that would come from an international view of the nutrition question.

"The second point is that popular interest in health questions—not just personal health, but public health—has increased during the war. Without the informed interest and consistent support of the mass of the people, we could not have maintained national health. There is a new interest in health as something positive, not merely freedom from disease. Health has become news, and Prevention is acquiring some of the drama of Cure.

Total war has made us realise more keenly than ever before in our history that it is upon the health of the people that all our power depends, and that better health cannot be secured without the full co-operation of the people themselves.

"The third lesson we in Britain have learned is the need to knit together and expand all the various health services. We have got more team-work in medicine; after the war we must achieve still more. His Majesty's Government has accepted the principle of a comprehensive National Health Service which will provide all forms of medical and hospital care for every man, woman and child in Britain, as a matter of citizen right.

"I am convinced that if the world is to cope effectively with the grave problems of control of disease which will arise in the post-war period, we shall need planned, *inspired* team-work in the international field, and a wide public recognition in the democratic nations of the global character of public health protection.

"Your Association has done magnificent work in the field of public health, work I may say which is continually watched and admired by the officers of my Ministry. May you long continue to carry the standard of progress!"

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Erich J. Arendt, M.D., Health Dept., Commerce St., San Antonio, Tex., Asst. Health Officer
- Frederick R. Bausch, M.D., City Hall, Allentown, Pa., Health Officer
- Roy E. Borrowman, M.D., 27 East St., Fort Edward, N. Y., Health Officer
- Lloyd A. Clarke, M.D., D.P.H., 22 Main St. W., Hamilton, Ont., Canada, Asst. Medical Officer of Health
- John W. Dabbs, M.D., Leflore County Health Dept., Greenwood, Miss., Director
- Thomas C. Hodgson, M.B., 197 Worthington Ridge, Berlin, Conn., Health Officer
- Major Robert W. Johnson, M.C., 407 N. Clements, Gainesville, Tex., Camp Medical Inspector, A.U.S.
- Charles W. Kelley, M.D., Box 748, Brownwood, Tex., Director, Brownwood-Brown County Health Unit
- Ronal B. Kirkpatrick, M.D., 918 Palm St., Abilene, Tex., City and County Health Officer
- Andrew O. Laakso, M.D., 27 Broad St., Danielson, Conn., Local Health Officer
- Florence E. MacInnis, M.D., Milwaukee City Health Dept., City Hall, Milwaukee, Wis., Medical Supt., Tuberculosis Division
- William R. Martin, M.D., Charlotte C. H., Va., Charlotte County Health Officer
- Dr. Antenor Miot, Les Cayes, Haiti, Administrateur, Service National d'Hygiene et Assistance Publique, Cayes
- Henry G. Morgan, M.D., Old Citadel, Charleston, S. C., Director, Venereal Disease Control, City and County Health Dept.
- Stenon Rey, M.D., Hospital Justinien, Cap-Haitien, Haiti, Public Health Officer, Service National d'Hygiene et Assistance Publique
- Samuel F. Ridings, D.D.S., 513 Walnut St., Greenville, Ohio, Member, Health Council, State Dept. of Health
- Arthur J. Schaible, M.D., Box 1330, Fairbanks, Alaska, Deputy Commissioner of Health, Territorial Dept. of Health
- Arthur J. von Werssowetz, M.D., Baroness Erlanger Hospital, Chattanooga 3, Tenn., Director, Venereal Disease Control Program, Hamilton County Health Dept.

Laboratory Section

- Jacques Archambault, D.Sc., 89 East, Notre-Dame, Montreal, Que., Canada, Chief

- Chemist, Div. of Laboratories, Ministry of Health
- Catharine Atwood, Bacteriological Laboratory, Haymarket Sq. Bldg., Boston, Mass., Bacteriologist, Health Dept.
- Walter C. Bartsch, 205 E. 24th St., New York, N. Y., in charge of Control Work and Laboratory, Pioneer Ice Cream Div., The Borden Co.
- Louis V. Blubaugh, Ph.D., 3853 Kirkup Ave., Kennedy Hts., Cincinnati 13, Ohio, Chief Bacteriologist, The Wm. S. Merrell Co.
- Frederick Boerner, V.M.D., 3403 Huey Ave., Drexel Hill, Pa., Bacteriologist, State Dept. of Health
- John H. Brewer, Ph.D., 1030 N. Charles St., Baltimore, Md., Director of Bacteriological Research, Hynson Westcott and Dunning, Inc.
- Esther E. Brintzenhoff, 407 Angell St., Providence, R. I., Bacteriologist and Serologist, Rhode Island Hospital
- Paul H. C. Brutsaert, M.D., 10 Sherman Ave., Bronxville 8, N. Y., Director of Laboratory, Belgian Congo
- Mayme C. Colvin, 519 Dexter Ave., Montgomery, Ala., Senior Serologist, State Health Dept.
- Saul Frances, M.S., Pease Laboratories, Inc., 39 West 38th St., New York 18, N. Y., Research Biologist
- David Kahler, 306 Garnet, Houghton, Mich., Bacteriologist, State Dept. of Health
- Fern K. Line, Rt. 1, Box 20, Okemos, Mich., Bacteriologist, State Dept. of Health
- Dorothy Novotny, Lederle Laboratories, Inc., Pearl River, N. Y., Bacteriologist, Testing Dept.
- Edith W. Pritchett, State Branch Laboratory, Tuscaloosa, Ala., Senior Bacteriologist, State Health Dept. Lab.
- Mrs. Sarah B. Stephens, P. O. Box 1139, Hartford 1, Conn., Senior Microbiologist, Bureau of Labs., State Dept. of Health

Vital Statistics Section

- Isidore Altman, M.S., 2733 S. Veitch St., Arlington, Va., Asso. Statistician, U. S. Public Health Service
- Marie-Louise R. Daste, M.A., 624 Lowerline St., Apt. M., New Orleans, La., Statistician, Div. of Public Health Statistics, State Health Dept.
- Albert P. Iskrant, M.A., U. S. Public Health Service, Washington 14, D. C., Senior Public Health Representative

Marion K. Macdonald, M.D., 156 Allen Place, Hartford, Conn., Interne, Long Island College Hospital, Brooklyn, N. Y.
 Christopher Tietze, M.D., 615 N. Wolfe St., Baltimore 5, Md., Research Associate, Johns Hopkins University School of Hygiene and Public Health

Engineering Section

Chesley W. Cochran, 114 E. Carson, Blackwell, Okla., Sanitarian, Kay County Health Unit
 Lieut. Yates Cook, 309 Hilltop Rd., Linthicum Heights, Md., Chief, Div. of Housing, City Health Dept.
 Herbert J. Dunsmore, 213 N. Liberty St., Marshall, Mich., Public Health Engineer, Calhoun County Health Dept.
 Raymond J. Faust, State Dept. of Health, Lansing 4, Mich., Sanitary Engineer
 William Adwin Ross, 221 S. 21st St., Richmond, Ind., Supt., Sewage Treatment Works, City of Richmond
 Ivan F. Shull, 8316 Carey Lane, Silver Spring, Md., Senior Sanitary Engineer, Office of Labor, War Food Administration
 Marvin L. Smith, 852 U. S. Custom House, Chicago, Ill., Sanitary Engineer, States Relation Division, U. S. Public Health Service

Industrial Hygiene Section

Rosa H. Clarke, R.N., Rt. 1, Manning, S. C., Consultant Nurse, Industrial Hygiene, State Board of Health
 Thomas P. Marsh, M.A., 116 Temple St., City Health Dept., Los Angeles 12, Calif., Asst. Industrial Hygiene Engineer, U. S. Public Health Service
 Lester V. Taylor, M.A., 405 Arlington Ave., Elmhurst, Ill., Supervisor of Food Inspection and Analysis, American Can Co.

Food and Nutrition Section

Edwin G. Applegate, 426 Burd St., Pennington, N. J., Senior Chemist, Food and Drug Bureau, State Dept. of Health
 David G. Graham, M.S., Box 308, Rogersville, Tenn., Supervisor, Farm Security Administration
 Estelle G. Hoffman, 311 South Allen St., Albany 3, N. Y., Nutritionist, State Dept. of Health
 Martin A. Hoffman, 5816 Clover Rd., Baltimore, Md., Junior Chemist, U. S. Dept. of Agriculture
 Ivan D. Jones, Ph.D., 2710 Rosedale St., Raleigh, N. C.
 Herbert E. Longenecker, Ph.D., Dept. of Chemistry, Univ. of Pittsburgh, Pittsburgh,

Pa., Professor of Chemistry and Director of Buhl Foundation Research Project
 Henry E. Medbery, 1128 Sixteenth St., N.W., Washington 6, D. C., Acting Director, Technical Service, American Bottlers of Carbonated Beverages

Maternal and Child Health Section

Mary E. Barnes, M.A., Room 320, State Health Dept., Atlanta, Ga., Nutrition Consultant

Public Health Education Section

Mayola S. Center, Room 240, State Office Bldg., Atlanta, Ga., Social Hygiene Consultant, State Dept. of Public Health
 Harold J. Cronin, D.M.D., 739 Liberty St., Springfield, Mass., Council on Dental Health, Massachusetts Dental Society
 Joseph M. Gantz, Ph.D., 312 W. 9th St., Cincinnati, Ohio, Asst. Secretary, Public Health Federation
 Oscar Gottfried, 1440 Broadway, New York, N. Y., Editor, The New York Physician
 George W. LaBrier, M.D., 1007 Ayres St., Corpus Christi, Tex.
 Dominick J. Lacovera, Ph.D., St. Agnes Hospital, White Plains, N. Y., Interne
 Margaret C. Lewis, M.D., 155 East 44th St., New York, N. Y., National Health and Safety Adviser, Girl Scouts, Inc.
 Gladys M. Park, R.N., 2 East 12th St., New York, N. Y., Secretary, Health Information Service, N. Y. Tuberculosis and Health Assn.
 Elliott C. Small, D.D.S., 239 E. 51st St., Chicago, Ill., Public Health Dentist, State Dept. of Public Health

Public Health Nursing Section

A. Evelyn Chesson, County Health Dept., Oxford, N. C., Staff Nurse, Granville County Health Dept.
 Nellie R. Dillon, R.N., 100 N. Main St., Providence, R. I., Director, Providence District Nursing Assn.
 Grace E. Euteneuer, R.N., 223 E. Dearborn St., Havana, Ill., Public Health Nurse, State Dept. of Public Health
 Elizabeth M. Evans, R.N., M.S., Box 221, Cordova, Alaska, Public Health Nurse, Territorial Dept. of Health
 Gladys L. Garland, 923 Fulton County Court House, Atlanta, Ga., Supervisor of Nurses, Fulton Co. Health Dept.
 Lucy C. Hawkins, R.N., M.A., 113 Winthrop St., Augusta, Me., Supervisor, Div. of Nursing, State Bureau of Health
 Mary M. James, 1903 Monroe St., Toledo, Ohio, Director, Toledo District Nurse Assn.
 Margaretta W. Potter, Stone House Farm,

Mendham, N. J., Board Member, Visiting Nurse Assn. of Somerset Hills
 Helen E. Ruppe, R.N., 614 South Morris Ave., Bloomington, Ill., Asst. Director of Nurses, St. Joseph School of Nursing
 Sarah B. Selterman, R.N., Orleans County Public Health Nursing Service, Medina, N. Y., County Nurse
 Marion E. Shand, 329 S. 17th St., Philadelphia 3, Pa., Executive Director, Starr Centre Assn.
 Dorothy D. Stewart, R.N., Room 601, Hotel Jamestown Bldg., Jamestown, N. Y., District Supervising Public Health Nurse, State Dept. of Health
 Vivian Visscher, 401 East Madison, Ann Arbor, Mich., Staff Nurse, Washtenaw County Health Dept.
 Janet F. Walker, School of Nursing, Catholic Univ., Washington, D. C., Director, Div. of Public Health Nursing

Epidemiology Section

Cecil K. Blanchard, 144 S. Main St., Pennington, N. J., Asst. Epidemiologist, State Dept. of Health
 C. Robert Hess, M.D., Insular Sanatorium, Ponce, Puerto Rico, Attending Physician
 Allan Hurst, M.D., 125 Worth St., New York, N. Y., Supervisor of Clinics, Bureau of Tuberculosis, Health Dept.
 Lt. Comdr. Louis C. Morris, M.C., U.S.N.R., Epidemiological Unit 24, Naval Operating Base, Norfolk 11, Va.
 Lt. Comdr. William A. Myers, M.C., U.S.N., N.C.T.C., Davisville, R. I., Epidemiologist, Ninth Naval District
 Lowell L. Stokes, M.D., Box 410, McMinnville, Tenn., Director, Div. of Venereal Disease, Warren Co. Health Dept.
 I. Jackson Tartakow, M.D., M.S.P.H., 10

Washington St., Hempstead, N. Y., Epidemiologist, Nassau County Dept. of Health
 Everett P. Veatch, M.D., M.P.H., P. O. Box 687, Pasadena, Tex., Control of Trypanosomiasis

School Health Section

B. Marion Hiltz, 40 Fairview Place, Santa Cruz, Calif., Supervising School Nurse, Santa Cruz City Schools
 Elizabeth J. McGinness, M.S., 1210 North Ave., North High School, Sheboygan, Wis.
 Bernice Moss, M.A., 221 State Capitol, Salt Lake City, Utah, State Director of Health, Physical Education and Recreation, State Dept. of Education
 Ethel Winn, Spencer Ave., Elwood, Ill., Supervising Nurse, Joliet Elementary Schools

Unaffiliated

John B. Alsever, M.D., U. S. Office of Civilian Defense, Washington, D. C., Surgeon (R), U. S. Public Health Service
 Arleen S. Barron, 818 Santa Ray Ave., Oakland, Calif., Laboratory Technician, Peralta Hospital
 Abraham O. Wilensky, M.D., 12 East 87th St., New York 28, N. Y., Practising Physician

DECEASED MEMBERS

Loneta M. Campbell, R.N., Cincinnati, Ohio, Elected Member 1934, Elected Fellow 1938, Public Health Nursing Section
 J. K. Gore, Orange, N. J., Elected Member 1921, Unaffiliated
 Ruth Ogden Pierson, East Orange, N. J., Elected Member 1917, Laboratory Section

NEWS FROM THE FIELD

PUBLIC HEALTH SERVICE ORDINANCE FOR EATING AND DRINKING ESTABLISHMENTS, 1943

The U. S. Public Health Service has published *Public Health Bulletin No. 280* (U. S. Gov. Ptg. Office, Washington, D. C., 20¢), representing the first printed edition of an ordinance and code recommended for adoption by local communities and states in order to encourage a greater uniformity and a higher level of excellence in the sanitary control of eating and drinking establishments. This edition replaces the mimeographed 1940 edition.

Among the changes made in this edition of the Ordinance and Code, there may be mentioned the inclusion of illustrations and explanatory material which has been improved and expanded; field tests have been provided for cadmium and cyanide, rebaking of cream-filled pastries or adequate boiling of the filling is required, running water under pressure is required, lavatories must be supplied with hot and cold running water, and the swab test technic given is that proposed in June, 1943, by the Subcommittee on Food Utensil Sanitation of the A.P.H.A. It is also provided that the restaurant building is required to be rat-proofed and training courses for food handlers are recommended.

VISITING PROFESSORS NAMED AT PUERTO RICO SCHOOL OF TROPICAL MEDICINE

Columbia University, New York, N. Y., recently announced the appointment of 5 visiting professors at the School of Tropical Medicine in San Juan, Puerto Rico, which is operated in connection with the University. The names of the new visiting professors are as follows: Dr. Ceil A. Watson, Dr.

Gustavo Pittaluga, Dr. Antonio Fernos-Isern, Dr. Tomas Blanco, and Dr. Joseph H. Bolton.

QUEBEC PRIESTS TO STUDY PUBLIC HEALTH AT YALE

Dr. Jules Gilbert, Director of Public Health Education, with the financial assistance of the Ministry of Health, Quebec, is collaborating with six teaching orders to send five Catholic brothers and two fathers to the Department of Public Health, Yale University School of Medicine, New Haven, for a year's training in health education and public health. On their return to Quebec they will devote themselves primarily to school health education work in the normal schools of their respective orders, in conjunction with the Ministry of Health. The group will consist of the following:

R.P. Roland Blondeau, Rosemont
R.P. Raymond Lavoie, Joliette
R.F. Berchmans-Eugène, Laprairie
R.F. Evan, Sorel
R.F. Gaston Quenneville, Outremont
R.F. Jean-Lucien, Granby
R.F. Rémi Donat, Iberville.

STAFF CHANGES, MEDICAL AND HEALTH SERVICES, AMERICAN RED CROSS

Albert McCown, M.D., Dr.P.H., has resigned as Director of Medical and Health Services of the American Red Cross to accept a commission as Lieutenant Colonel in the Medical Corps, A.U.S. and is leaving shortly for a foreign assignment with the Allied Military Governments.

G. Foard McGinness, M.D., Dr.P.H., the director of Medical and Health Services for the Midwestern Area, American Red Cross, St. Louis, has been appointed acting director of Medical and Health Services at Na-

tional Headquarters of the Red Cross, Washington.

Amos G. Christie, M.D., of Washington has resigned as assistant director of Medical and Health Services, American Red Cross, as of October 1, to become Professor of Pediatrics at Vanderbilt University School of Medicine, Nashville, Tenn., succeeding the late Horton G. Casparis, M.D.

AMERICAN STANDARDS ASSOCIATION REVISES CODE FOR ABRASIVE WHEELS

The American Standards Association has announced approval of an important revision of the Abrasive Wheel Safety Code, the first revision since 1935. New sections have been added to keep pace with changes in the industry. Completely new rules have been written for mounted wheels. New speed rules have been drawn up for crankshaft grinding, camshaft grinding, and thread grinding operations. While the basic speed tables remain the same, the Code has been carefully reviewed and many points have been clarified. Need for a revision of the Code became increasingly apparent during the period of expanding war industries. Several types of abrasive wheels and grinding operations which previously had very limited usage, found an important place in the new industries. The *Safety Code for the Use, Care, and Protection of Abrasive Wheels* (B7-1943) may be obtained from the American Standards Association, 29 West 39th Street, New York 18, N. Y., at 35 cents per copy.

HEALTH UNIT IN VERA CRUZ

The *Journal of the American Medical Association* reports that the Department of Health of Mexico has entered into an agreement with the School of Medicine at Tulane University, New Orleans, to establish a health unit and field training station at Boca del Rio, Vera Cruz, Mexico. The unit will

function as a health center for the welfare of the community and serve as a training center for physicians named by the Department of Health of Mexico or by the University with the approval of the Mexican Department.

SIR ARTHUR NEWSHOLME'S BEQUEST

Science reports that Sir Arthur Newsholme, who died on May 17, bequeathed the residue of his estate to the London School of Hygiene and Tropical Medicine.

REFRESHER COURSE IN TROPICAL MEDICINE

The South Dakota State Board of Health in coöperation with the U. S. Public Health Service sponsored a series of lectures on tropical diseases to medical students in six areas of South Dakota. M. Fernan-Nunez, M.D., Professor of Pathology and Tropical Medicine, Marquette University Medical School, Milwaukee, was the speaker. Dr. Fernan-Nunez also lectured at Camp McCoy, Wisconsin, in September on Malaria.

NEW YORK STATE STAFF MEMBERS STUDY TROPICAL DISEASES

New York State *Health News* reports that Robert F. Korn, M.D., Dr.P.H., Epidemiologist on the staff of the Division of Communicable Diseases, has been granted a leave of absence for special study and clinical observation of tropical diseases. He will spend two months in tropical medicine at the Army Medical School in Washington and then travel to Honduras and Guatemala, Central America, as a member of the faculty of Albany Medical College, under the program sponsored by the Association of American Medical Colleges.

Paul A. Lembcke, M.D., District Health Officer of the State Department of Health, has just returned from a trip to Costa Rica and Guatemala where

he was sent as a member of the staff of the University of Rochester Medical School to obtain clinical experience in the tropical diseases.

Albert H. Harris, M.D., Associate Bacteriologist in the Division of Laboratories and Research of the department attended the course in tropical and military medicine given at the Army Medical School which ended in June.

OFRRO APPOINTMENTS

The Office of Foreign Relief and Rehabilitation Operations of the U. S. Department of State has announced the appointment of Margaret G. Arnstein, R.N., recently of the New York State Department of Health, and of Therese Kerze, R.N., formerly Assistant Director of the Judson Health Center, New York, as Senior Public Health Nursing Officers in OFRRO. Both of the appointees are spending a brief period in Washington for training purposes before going overseas. The current intensive orientation and training course includes 22 persons for a period of 4 to 6 weeks.

NUTRITION FOUNDATION RESEARCH

Annually \$237,000 is now being contributed by 37 food and related manufacturers to the Nutrition Foundation in support of basic research in the science of nutrition, according to a statement made by George A. Sloan, President of the Foundation.

It was also announced that Abbotts Dairies of Philadelphia and the American Lecithin Company of New York have become Sustaining Members of the Foundation. C. R. Lindback, President of Abbotts Dairies, and Adrian D. Joyce, Chairman of the American Lecithin Company, have become members of the Board of Trustees, which consists of 11 representatives from the public and 33 from industry.

Mr. Sloan stated that the Nutrition

Foundation is now supporting 70 basic studies in 38 institutions in the United States and Canada. On the recommendation of the Scientific Advisory Committee of the Foundation, grants-in-aid amounting to \$302,840 have been paid to these institutions since the organization of the Foundation on March 12, 1942.

PERSONALS

Central States

ADDISON D. ALDRICH, M.D., of Houghton, Mich., has been named Director of the Houghton-Keweenaw-Baraga Health Department.

HENRY H. ASHER, M.D.,† of Topeka, Kans., has resigned as Director of the Division of Local Health of the Kansas State Board of Health, to become Health Officer of Alger and Schoolcraft Counties, Mich.

JOSEPH H. CHIVERS, M.D., Medical Director of the Crane Company, Chicago, Ill., has been appointed Chairman of the Advisory Committee to the Illinois State Division of Industrial Hygiene, succeeding the late PHILIP H. KREUSCHER, M.D.

MORDECHAI A. ELSTEIN, M.D.,† of Escanaba, Mich., was recently named Health Officer of Delta County, it is reported.

SYDNEY J. HEELEY, M.D., of Barton, Ohio, has been appointed Health Commissioner of Jefferson County.

JEROME J. SIEVERS, M.D., M.S.P.H.,* who has been Assistant to the Chief of the Division of Communicable Diseases, Illinois State Department of Health, and formerly a district health superintendent, has been appointed Assistant State Health Director of the Department under ROLAND R. CROSS, M.D., Director.

Eastern States

NEWTON J. T. BIGELOW, M.D., of Brentwood, N. Y., Clinical Director

of the Utica State Hospital, Utica, N. Y., has been appointed Superintendent of the Hudson River State Hospital, Poughkeepsie, N. Y., and Acting Assistant State Commissioner of Mental Hygiene. Dr. Bigelow will "fill the military absence of the present Assistant Commissioner, HARRY BECKETT LANG, M.D., of Albany."

JOHN MOORE CAMPBELL, JR., M.D., former Director of Health Conservation, has been appointed Deputy State Secretary of Health in Charge of Medical Affairs in Pennsylvania, Harrisburg, Pa. Dr. Campbell has been a member of the State Health Department for many years.

WARREN B. RAWLINGS, V.M.D.,† has resigned his position as Assistant Director of the Biological Laboratories of the Pitman-Moore Company, Zionsville, Ind., to accept a position as Production Director of the Reichel Laboratories, Inc., Kimberton, Pa.

CYRIL TASKER entered upon his duties as Director of Research of the American Society of Heating and Ventilating Engineers, New York, N. Y., on October 1. For the past 13 years, Mr. Tasker has been a member of the staff of the Ontario Research Foundation and carried on investigations relating to fuels and a variety of problems connected with heating and air conditioning.

NEAL N. WOOD, M.D.,† of Mackinac Island, Mich., Health Director of Charlevoix, Emmet, Otsego, and Antrim Counties, has been appointed in charge of the Bay County Department of Health, succeeding DOUGLAS A. FRYER, M.D., D.P.H.† Bay City, resigned.

Southern States

CHARLES E. BALLARD, M.D., of Alledale, S. C., former Health Officer for Oconee and Pickens Counties, has

been appointed Health Officer for Beaufort County. EDMOND J. BRYSON, M.D., of Liberty, former Health Officer of Greenwood County, will now serve in this capacity in Oconee and Pickens Counties, and MAULDIN J. BOGG, JR., M.D., of Abbeville, Health Officer of Abbeville and McCormick Counties will also direct the Greenwood County Health Department until a successor to Dr. Bryson is named.

AGNES L. BROWN, M.D., of Hardinsburg, Ky., has been named Health Officer of Muhlenberg County.

BENJAMIN M. DRAKE, M.D.,† of Carthage, N. C., has been appointed full-time Health Officer of Rockingham County, succeeding DOUGLAS H. FLYER, M.D.

JACOB D. FARRIS, M.D., formerly college physician at Eastern Kentucky State Teachers College, Richmond, Ky., now occupies a similar position at Emory University, Atlanta, Ga.

THEODORA A. FLOYD, R.N.,† former Associate Director of Public Health Nursing in the State Department of Health in Georgia, has been appointed Regional Consultant Nurse for the Children's Bureau in the Southeastern area, with headquarters in New Orleans. Miss Floyd was formerly the MCH Consultant Nurse in the Territorial Department of Health in Hawaii and Director of the Public Health Nursing course at the University of Hawaii.

O. M. GOODLOE, M.D., C.P.H.,† who has been Assistant Director of the Bureau of County Health Work in the Kentucky State Department of Health, Louisville, has been appointed Deputy Health Officer and Director of the Bureau of Maternal and Child Health in the Health Department in Peoria, Ill., under Dr. S. M. MILLER,* Commissioner. His appointment was effective October 1.

PHARES Y. GREENE, M.D.,† of Graham, N. C., has resigned as Health Officer of Alamance County, effective August 1, to devote his full time to private practice.

JAMES F. HACKNEY, M.D., M.P.H.,† has been made Director of the Health Department of Atlanta, Ga.

ROBERTS A. HEARN, M.D.,† assigned by the U. S. Public Health Service as Director of Industrial Hygiene, Arkansas State Board of Health, has resigned to become Medical Director of the Indiana Division of the Republic Aviation Corporation, it is reported.

EDWARD ALEX HEISE, M.D.,† has been appointed to direct the Sumter County Board of Health for the City of Sumter and Sumter County, S. C.

ROSCOE P. KANDLE, M.D., M.P.H.,† of the Calcasieu Parish Health Unit, Lake Charles, La., has been appointed Director of the Division of Local Health Service, Louisiana State Department of Health, New Orleans. This position was formerly held by C. L. MENGIS, M.D.,† who has been appointed Director of the Ouachita Parish Health Unit, Monroe, La.

EDMOND G. KLAMKE, M.D., M.P.H.,† formerly Director of the Webster Parish Health Unit, has been appointed Director of the Alexandria-Rapides Health Department, and Health Officer of Rapides Parish and the City of Alexandria, La.

ELIAS W. LANGS, M.D.,† Assistant Surgeon, U. S. Public Health Service, has been appointed Health Officer of Norfolk County.

LLOYD W. LUTTRELL, M.D., of Walterboro, S. C., has been appointed to direct the health department of Colleton and Hampton Counties which have been combined into one unit.

CHESTER R. MARKWOOD, M.D.,† of Glasgow, Ky., has resigned as Health Officer of Allen, Barren, and Monroe

Counties, to engage in private practice at Cave City.

DONALD B. McMULLIN, Sc.D.,† Associate Professor and head of the Department of Hygiene and Public Health and Associate Professor of Bacteriology, University of Oklahoma, School of Medicine, Oklahoma City, Okla., was selected by the Committee on the Teaching of Tropical Medicine of the Association of American Medical Colleges to go to Central America during the month of September to observe methods of tropical disease control. Dr. McMullen was to spend about three weeks at a United Fruit Company Hospital and at least a week with the local field unit of the office of the Coördinator of Inter-American Affairs.

WILLIAM G. MORGAN, M.D., of Owensboro, Ky., recently resigned as Director of the Daviess County Health Department, to accept a similar position in Montgomery County.

JAMES O. NALL, M.D., of Marion, Ky., has resigned as District Health Officer of Crittenden, Lyon, and Caldwell Counties, to devote his time to private practice.

CHARLES P. POPE, M.D. JR., Health Officer of Chesterfield-Marlboro Health District, has been appointed to a similar position in Aiken County, S. C.

J. ALLEN SCOTT, Associate Director of the Division of Malaria and Hookworm Service, Georgia Department of Public Health, has resigned to become Senior Statistician of the Division of Vital Statistics of the U. S. Bureau of the Census, Washington, D. C.

SAMUEL D. STURKIE, M.D., former Health Director for the Marion-Bristol area, has been named Director of Public Welfare in Lynchburg,

Penicillin Treatment of Early Syphilis*

A Preliminary Report

JOHN F. MAHONEY, M.D., R. C. ARNOLD, M.D., AND
AD HARRIS

U. S. Marine Hospital, Staten Island, N. Y.

THE number of diseases and infections which are favorably influenced by penicillin therapy continues to increase as experience in the use of the drug is gained. It is the purpose of the present report to record, in a preliminary way, certain observations which have been made in four patients with early syphilis (primary) who were treated with penicillin only.

A study of the usefulness of the drug in the management of syphilis was undertaken after limited animal experimentation indicated that penicillin

possessed some spirocheticidal activity. The plan of study embraced the concurrent carrying out of a complete delineation of the effectiveness of the drug in experimental syphilis in rabbits and the conduct of a small pilot study of the effects produced in patients with early disease. The prompt resort to the human being was sponsored by the general non-toxic character of the drug and by the knowledge that observations as to early effectiveness could be carried out without placing in jeopardy the patient's chance for ultimate recovery in event it became expedient to resort to conventional arsenic therapy.

The early results in the animal phase of the general study indicate that the time-dose relationship will prove to be as important in this therapy as in the use of other chemotherapeutic agents. Failures to sterilize experimentally infected animals with treatment schedules which utilize minimal amounts of the drug over a brief treatment period are predictable. The results from treat-

* From U. S. Marine Hospital, Staten Island, N. Y. Medical Director William Y. Hollingsworth in Charge.

This study was undertaken at the request of the Committee on Chemotherapeutic and other Agents, Division of Medical Sciences, National Research Council, acting for the Committee on Medical Research of the Office of Scientific Research and Development. The penicillin was furnished through a contract between the Office of Scientific Research and Development and the Massachusetts Memorial Hospitals.

Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

ment schedules which utilize larger amounts of the drug and more prolonged treatment periods will require observation for approximately one year for complete evaluation.

Four male patients have been treated and observed for a period sufficiently long to permit comparison with results produced by more conventional forms of treatment. Each patient displayed a single penile ulceration. Darkfield examination revealed characteristic *Treponema pallidum* in numbers varying from 2 to 10 per microscope field. The duration of the ulcerations averaged 8 days. Not any local or systemic therapy was employed other than that recorded below. The serologic status prior to therapy is indicated in the individual charts.

The penicillin treatment consisted of an intramuscular injection of 25,000 units of the drug at 4 hour intervals, night and day, for 8 days. The total number of injections was 48, and the total amount of the drug was 1,200,000 units. The gluteal muscle was the site of injection.

Darkfield studies of secretions collected from the primary lesions were carried out at 4 hour intervals following the beginning of treatment. Not any spiral forms were observed after the 16th hour.

Some mild but definite clinical manifestations were observed during the first 8 hours of treatment. The patients complained of general malaise and mild headache. Temperature elevations not in excess of 2°F. were recorded. The penile lesions became painful and the regional lymph glands became enlarged and tender. One patient displayed a maculo-papular skin eruption resembling secondary syphilis over the trunk and thighs. The eruption was of short duration. No symptoms, either early or late, were observed which could be construed as representing toxic response to the drug. The repeated use of the gluteal

muscles as a site for injection did not give rise to irritative sequelae.

Because of the importance of the serologic reactions as an index of the response to treatment, a comprehensive routine of serodiagnostic tests was employed. As representative of the super-sensitive procedures, the Kline Exclusion method was included. Of the flocculation tests set at a diagnostic level, the Kline Diagnostic, the Kahn Standard, the Eagle, Hinton, and Mazzini were employed. The Kolmer technic was the only complement-fixation method used. In addition to the above, quantitative titrations were carried out utilizing the Kolmer, Kahn, and Mazzini methods. The results produced by the various methods are displayed in the individual charts.

The results of the blood studies indicate that the therapy was responsible for a more or less rapid and complete disappearance from the blood stream of the reacting substance which is measured by the various tests and which is usually associated with activity in early syphilis.

The further observation of the group of patients will be maintained upon a weekly basis for as long as possible for the purpose of detecting any tendency toward a recurrence of positive serologic findings and for the recording of evidence of clinical relapse. The patients will again be hospitalized for the collection of a specimen of spinal fluid and for a complete medical survey at the expiration of 6 months post-treatment observation. Subsequent hospitalization for special study will be repeated as frequently as may seem desirable. To the information supplied by this group will be added the contributions supplied by additional patients treated in an identical manner until the total material is of dimensions which warrant the drawing of final and sound conclusions.

Should the more extensive and pro-

longed experience confirm the impression which is to be gained from the pilot study, a rebuilding of the structure of syphilis therapy may become necessary. The development of an optimal therapy will require carefully controlled studies designed to determine the most effective relationship between the amount of drug and the duration of the treatment period. Also the rôle of the treatment in latent disease and visceral and central nervous

system syphilis will require careful scrutiny before the reasonably effective measures which are available at present may be replaced by a therapy based upon penicillin. Because of the long post treatment period of observation which is a requisite for the evaluation of a syphilis therapy, the progress toward the adoption of a new mode of treatment must, of necessity, be deliberate.

Penicillin Therapy in Sulfonamide-Resistant Gonorrhea in Men*

C. J. VAN SLYKE, M.D., R. C. ARNOLD, M.D., AND
M. BUCHHOLTZ, M.D.

U. S. Marine Hospital, Staten Island, N. Y.

BECAUSE of the limited supply of penicillin, most of which is required for the treatment of the more serious infections, the developmental work in penicillin therapy of gonorrhea has not advanced as rapidly as might seem desirable. The results recorded herein indicate, however, that a larger supply may significantly affect both the method of treating the individual patient and the incidence of the disease.

Up to the present only two reports dealing with the general subject have appeared in American literature. The initial publication was that of Herrell, Cook, and Thompson¹ which presented the results obtained in the treatment of 5 patients with sulfonamide-resistant gonorrhea. Intravenous administration was practised and the results were favorable. The second report² dealt with the preliminary findings in a group of 75 male patients treated with penicillin in a uniform manner.

This second report is reviewed briefly in order to correlate it with the results of the later time-dose ratio investigations.

The patients included in the previously reported group were young men in a good state of health with the exception of the gonococcic urethritis.

All had failed to attain cure through one or more courses of sulfonamide drugs. The average duration of disease at the time of penicillin therapy was 45 days. The diagnosis was confirmed by positive spread and culture findings. The treatment consisted of the intramuscular injection of 10,000 units of the drug every 3 hours for a total of 16 injections. This schedule provided a treatment period of 45 hours.

This therapy resulted in 74 satisfactory results and one instance of failure which could be directly charged to the drug. An additional patient underwent a recurrence of clinical gonorrhea and has been classed as a relapse, although the possibility of reinfection was present. There was no evidence of immediate or delayed toxicity.

The routine dosage of 160,000 units of penicillin over a 45 hour period, represented an arbitrary selection. That it represented the use of an excessive amount of the drug was appreciated. The second portion of the general study concerns itself with the determination of the minimal amounts of drug and the shortest treatment period which would produce an acceptable cure rate. In approaching this problem varying schedules of dosage and treatment periods were surveyed in 5 additional patient groups. As in the preliminary group of 75 patients, penicillin was administered intramuscularly to these patients only after the diagnosis had been con-

* From U. S. Marine Hospital, Staten Island, N. Y. Medical Director William Y. Hollingsworth in Charge.

Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

CHART I

<i>Penicillin Therapy in Gonorrhea</i>					
<i>Group</i>	<i>Number Treated</i>	<i>Number Cured</i>	<i>Number of Doses</i>	<i>Units per Dose</i>	<i>Total Dosage</i>
<i>A</i>	75	74	16	10,000	160,000
<i>B</i>	23	23	5	20,000	100,000
<i>C</i>	25	21	4	25,000	100,000
<i>D</i>	25	24	5	15,000	75,000
<i>E</i>	15	12	5	10,000	50,000
<i>F</i>	15	15	6	20,000	120,000

firmed by culture findings. These further treatment schedules were as follows:

Schedule B—There were 23 patients in this group; 21 had not responded to previous sulfonamide therapy. Each received 5 intramuscular injections of 20,000 units of penicillin at 3 hour intervals. The period of treatment was 12 hours, and the total amount of drug, 100,000 units. All of the patients of this group satisfied the criteria of cure and in follow-up observations, amounting to 14 weeks in some instances, did not show any tendency toward a recurrence of symptoms.

Schedule C—A total of 25 patients were treated by intramuscular injections of 25,000 units given at 3 hour intervals for a total of 4 injections. Eight had not received sulfonamides. The total amount of drug was 100,000 units, and the treatment period 9 hours. Twenty-one of the patients of this group

attained satisfactory results and 4 failed.

Schedule D—In this series of 25 patients, 6 of whom were without previous sulfonamide therapy, the total dosage was reduced to 75,000 units. Injections of 15,000 units were given at 3 hour intervals, a total of 5 injections covering a 12 hour treatment period. There was one patient in this group who was classed as a treatment failure.

Schedule E—In a group of 15 patients (only 2 had not been treated with sulfonamides) the total amount of drug was reduced to 50,000 units. Intramuscular injections of 10,000 units were given at 3 hour intervals for a total of 5 injections over a treatment period of 12 hours. Three of the patients of this group were classed as treatment failures. Two of these three failure cases were treated a few days later with a total of 120,000 units as described in Schedule

F. Both of these patients were cured.

Schedule F—A total of 15 patients were included in this series. Sulfonamide therapy had failed in 11 of the 15. The total dosage was increased to 120,000 units administered at 3 hour intervals for 6 injections over a treatment period of 15 hours. All of the patients in this group were classed, tentatively, as having attained cure status. This group was in the process of being expanded to adequate proportions at the time this research was halted.

DISCUSSION

The response of gonorrhea to penicillin therapy has been dramatic. The matter of ascertaining the minimal amount of the drug which is effective is important because of the limited supply, cost, and usefulness of the drug in more serious infections. From the results obtained by the patients in the various groups it seems logical that one optimal treatment routine will call for 120,000 units of penicillin administered over a 15 hour period. It is obvious that the group must be enlarged before final conclusions can be drawn and that

further experience may point to a more accurate refinement of this schedule.

Because of the present need for conserving penicillin a second optimal treatment schedule could call for 50,000 units, possibly similar to that employed in Schedule E, and the re-treatment of the failures with larger dosage.

There was no apparent difference in the response of gonococcic infections to penicillin between untreated patients and those who had failed to respond to the administration of sulfonamides.

CONCLUSIONS

A treatment schedule consisting of 6 intramuscular injections of 20,000 units of penicillin, administered at 3 hour intervals over a treatment period of 15 hours, was found to be satisfactory in the management of gonorrhea in men.

Planning Today for Public Health Administration Tomorrow^{*}

FELIX J. UNDERWOOD, M.D., F.A.P.H.A.

Secretary and Executive Officer, State Board of Health, Jackson, Miss.

MEASURED by individual and collective health of our people, we, as public health workers, can derive satisfaction from our view of the attainments which have led up to the present state of efficiency in our field. As we make ready to tackle further and more difficult problems, we gain a new enthusiasm from obstacles already overcome. A review of public health progress and developments at each annual meeting, serving as it does as a tonic and a stimulus to further achievement, has become traditional. However, the urgency of the conference this year suggests that we omit this time-honored reflection in the interest of more pressing considerations.

Since the outbreak of the war, public health has gone far in protecting troops and civilians alike from disease. Measures developed during peacetime and wartime have been put to work on every front, with the result that few serious epidemics have occurred. The health status of the American people has been comparatively good. This contribution to the efficiency of the war effort and to ultimate victory is recognized.

Now that we are beginning to turn our eyes to the winning of the peace, it becomes no less important that we have a strong, physically fit population. Civilization will have to be rebuilt on

a more enduring basis, and public health will be a vital factor in attaining this goal. Already it is one of the principal subjects of discussions and considerations of post-war planning by medical and public health organizations in this country.

As distances evaporate, we suddenly find ourselves one large neighborhood or community in which there can be no absolute or lasting security for any one group unless such security be provided for all. Particularly is this true with regard to *health* security. Many diseases which seem remote because of our excellent public health structure, which it has taken more than seventy years to build, still present a problem in other areas not so fortunate as to have the benefit of years of health experience. Transmission of these diseases to the unaffected populations grows increasingly apparent. The speed of air travel from every section of the globe will make it difficult always to detect disease carriers. Likewise, the dislocation of populations presents problems of tuberculosis control, dysentery, malaria, and others unless health measures for control are adequate. Potentially dangerous conditions which might establish new disease problems in this country or aggravate old ones loom on the public health horizon at this time and present a maze of new and complex problems for solution. Whatever ingenuity and resourcefulness may be necessary to untangle these problems, public health

^{*} Presidential Address delivered before the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

forces in this country as well as in other countries can be counted upon to apply. Public health workers have never shied away from hard and difficult tasks and they will not do so now when so much depends upon individual and collective efforts.

These goals which we are setting call for a public health organization of the most efficient character. Planning is already under way. Urgency of immediate needs must not be allowed to overshadow the plans for the future. Our public health plans for the future—that is, after the war—are being laid now, notwithstanding the extreme shortages of public health and medical personnel taken up by the armed forces and war industries. I am thinking particularly of diseases that may be brought home from the battlefields of the world, especially tropical diseases such as various forms of malaria and the dysenteries, because until recently medical science had been unable to cope successfully with these diseases. Efforts of all public health workers must be combined with sound, intelligent thinking and action. Make no mistake, there is a tremendous job ahead. If it is well executed, there will be few idle moments on anyone's hands.

It is believed necessary to consider first our doorstep problems. The word "doorstep" is preferred to "home front" because we certainly must remove whatever is on our own doorstep before we can travel beyond.

Doorstep diseases that present a serious threat to public health and will respond to a sound program of control are the deficiency diseases, malaria, gastrointestinal ailments, typhoid fever, various infectious diseases, and problems of rehabilitation arising out of the war. We must catch up with the work which was already pending before this crisis—and some of it has been pending for fifty years. To tolerate the existence of wholly preventable diseases in our midst

(typhoid fever as an example) is disgraceful. We can and must eliminate these conditions responsible for lowering the physical and economic status of our people. This is our first mission as public health workers.

Personal application and appreciation of public health is an essential doorstep problem. Absorption of the great public health truths because of association with public health has not worked. Some guidance is absolutely necessary.

Too few of the health departments of the country are following the notable example of efficient industrial organizations and others in keeping employee health records. From the standpoint of the organization and the individual, is it not a good thing? We cannot hope for the most effective results in our health teachings until such time as public health workers personally apply the protective measures they advocate. The fact that great numbers are not now doing so would indicate a need real and urgent. There has been a tremendous turnover in personnel since the outbreak of the war and a fertile field provided for educating a large number of people. Many of these new workers have had their first glimpse into the workings of public health. The requirements for a health check-up periodically must be set forth. Human nature being what it is, some prodding is often necessary among the best of us. This should, therefore, be the responsibility of the organization. Essential records should be kept for the purpose of informing individuals of such things as needed immunizations, chest x-rays, laboratory tests, periodic physical check-ups, dental certificates, and so on. Once such a routine is established, the employee will discover the security and satisfaction which comes from eliminating preventable disease worries and physical incapacities. Active tuberculosis in a health department spreads in the same way as active

tuberculosis outside the health department. As depicted in "Susan and God," sometimes it seems that we go forth in every direction to do public good, leaving our own household unattended.

And still another doorstep problem is the organization of public health at the local level. Until each of the more than three thousand counties in the United States has within reach, either through a district health department or a county health department, full-time health protection, we should not consider lend-leasing public health. Like schools, churches, post offices, public health must be "on the ground" to serve the people. And just one word in behalf of housing community health programs: We should not be satisfied to undertake one of the most important social security programs from the basement of the courthouse or the third floor of a run-down office building. We should insist upon adequate public health facilities.

The horizon of public health presents many problems which must be solved without delay. There is a clamor for increased services in every direction. This tremendous load thrust upon the shoulders of public health would be too great a task to assume alone; but the vast facilities of the medical, dental, nursing and allied professions are being utilized. Participation on the part of physicians, public health workers, and others is necessary, but it is likewise necessary that the individual be urged on by education to assume an increasing share of personal responsibility for putting to work the vast knowledge which has been accumulated regarding sound health practices. Long-wished-for development of effective measures against such diseases as malaria, cardiovascular diseases, cancer, tuberculosis, virus infections, and certain mental afflictions will provide still further public health tools to utilize in the program

for the welfare of mankind. In the meantime, while looking forward in happy anticipation to such developments, it might prove of more immediate value to try to perfect some of the tools we already have—many becoming rusty from disuse.

To prevent physical incapacities and disease and to promote health, the periodic health check-up for the general population has long been a paramount item in our public health teaching. No worker has failed to point out its value. If we are to keep faith with those to whom we have advocated this procedure, I think it is time to plan for a greater thoroughness in its performance. The American Medical Association, in its desire to help the physician to fulfill certain minimum essentials in conducting the periodic health examination, has issued a manual. In the hands of every member of the profession, this manual would be a public health wedge. In the introductory pages the following statements are found:

The periodic health examination serves to measure the present health status of the individual, subject to the qualification that obscure or insidious disease may not always be discoverable by methods at present available. Further, the examination discloses habits of living and environmental factors which may be unhealthful but susceptible of correction. Finally, of course, it gives opportunity for treatment of early or pre-clinical stages of disease . . . The personal health inventory or periodic health examination, under whatever name it may become most widely known, must be regarded as a concept which has appealed to the intelligent elements of the American people to a somewhat limited extent, but which has in it enough promise of better health to warrant its more widespread popularization and adoption by increasing numbers of our people.¹

Other groups share the responsibility for the public's lack of response to this vitally important health measure. If we hope to divert the public from the ineffective over-the-counter drugstore

practice and the resort to numberless proprietary remedies and patent medicines, to say nothing of the illegal practitioners, something specific must be set forth. Once this is accomplished by a competent committee, such as may be found within the American Medical Association, and put into force by the nation's physicians, one of the major hurdles will be over. Having something definite to sell, it will be much easier for the advocates of the health check-up to sell it.

Sufficient experience in recent years enables the keen observer to realize that a greater program of physician-public health coöperation and participation is not only desirable but also essential in accomplishing the task before us.

Consider the venereal disease program as one example of a disease problem involving great numbers of the population, and presenting a constant threat to public health. It is inconceivable that the progress made to date could have been achieved by either the medical profession or public health organizations working independently of each other. All along, we need a program of participation of physicians aiding the public health program and the health department helping the physician—both serving the health needs of the individual. The dental profession has also coöperated in the public health program and made possible greater progress in this direction. Hospitals are now coöperating with public health in making available service for the wives of soldiers under the emergency maternity and infant care program.

Today we turn our thinking to all community resources realizing that without them our efforts will fail. Brought closer together by the emergency of war, we will not relax our efforts and will not allow worth while programs to decay because of lack of pressure caused by the emergency. I

do not need to point out to you what became of our venereal disease program after the last war—but let this be a reminder that the momentum behind our programs established on a wartime basis must be great enough to continue these as peacetime programs, if need still exists.

As we look ahead, there should be a joining of hands and of hearts of all forces. We now prepare for one of the biggest jobs of all times—that of rehabilitation, rebuilding, and restoration. The states owe a great deal to the U. S. Public Health Service, the Children's Bureau, and other federal agencies, and nonofficial agencies for their fine coöperation and economic assistance. Greater uniformity of procedure among all the states has been achieved as a result of the federal-state relationship in public health. It is true that federal-state relationships with respect to public health administrative policies might be strengthened and made more effective in some instances. We all realize that personnel delegated to work with state and local forces on wartime public health programs have injected varying policies with regard to salary scale, hours of employment, leave, and so on, into public health administration. These obstacles though not great have caused conflicts within the organization. It would doubtless be difficult to have these employees conform fully to the policies of the organization to which they are assigned, but, in due time, these problems will be eliminated.

Thinking of the need of this federal assistance, there is brought forcibly to our attention the impact of the demand for birth certificates created by the war. States operating on a two year appropriation could not expand sufficiently to meet this overwhelming demand, and if it had not been for the fact that we were able to use a small amount of federal funds to keep our heads above water, we would not today be able to

have this important function retained where it rightfully belongs. Being aware of the importance of these vital records to the health program of the United States, a transfer of this function is being sought in order that the U. S. Public Health Service may assist the state divisions of vital statistics to improve registration and to render to the citizens of the states a uniform service. Without such assistance, the states will carry on a less effective service. This is one field that has not been covered by federal assistance in previous years. We have not tapped our resources with regard to public health statistics.

There are other fields opening up for federal assistance. Heretofore, states have operated tuberculosis hospitals and mental hospitals without federal assistance. These might be materially benefited if federal assistance were available. The field here is fertile. For years we have known the value of isolation and early treatment of cases in disease control. Facilities should be made available for an extension of these weapons.

Federal-state relationships can always be maintained on a mutually agreeable basis if each is alert and open-minded. We must guard against invasion of domains, but likewise we must welcome outside assistance that will strengthen. If disease recognizes no barriers and travels freely from one state to another, then public health regulations in certain instances will have to know no barriers and will have to look to interstate control measures. This same policy will one day be applied to global thinking as stricter examinations are required of those entering this country. We help most when we help others to help themselves. This should be our test of assistance whether it be at the global level, the federal level, the state level, or the local level. And our programs of assistance should always be tested by the one measuring rod that will always

keep us in the middle of the road in so far as policies and procedures are concerned—"We should not do for the individual what the individual can well do for himself."

We have not been neglecting altogether global health. Today American-trained public health workers are in Alaska, India, South America and Central America, several European countries, and all places where our armed forces now are operating. As we improve and make more effective our own local public health program, we cultivate a fertile field for the training of global public health workers. We can be of no greater assistance to our neighbors in this world community than to afford opportunities for observation and training. In so far as we ourselves build a sound public health program we assist our neighbors. To assist us in this field, we can now draw upon improved facilities for diagnosis and treatment made possible during the past few years and by wartime developments. Yesterday a chest x-ray was available only to a few; today it may be used as a part of a routine periodic check-up.

In entire counties in many sections of the country all of the public school teachers and pupils of every grade in the school are being given physical examinations periodically—examinations which include chest x-rays, blood tests, and other necessary laboratory tests. This is routine in many of our American communities. All of this and more will be available to people of all countries of the world when the value of public health is accepted internationally.

Greater laboratory facilities, and other aids to diagnosis have brought us a great distance. All of these will be helpful, and we can rightfully expect to see public health integrated into the post-war pattern. It is up to us to furnish the cloth—or the trained public health workers. If we were to say today that we need five thousand trained

public health workers, not one of us could point to a supply. However, if tomorrow we need ten thousand trained public health workers, some of the supply will come from definite training programs which are being instituted in each of the forty-eight states by means of federal assistance, interested philanthropic foundations and funds in this country. The supply of nurses will be greatly increased. The need for trained workers cannot be given too much emphasis. Today we have workers trained in the science of public health to carry on the program. Our number, however, is entirely too small for present, to say nothing of future, public health needs.

Like a pebble dropped in a pool, public health begins with the smallest area (the family), then extends to the community, the state, and the nation, and now may extend to all shores be-

yond. From this close association as a member of a world neighborhood, we will benefit from an exchange of ideas, from an exchange of public health plans. Public health seed can grow where the soil is fertile, where public opinion is favorable. Much soil must be fertilized. The maximum development of the individual from the standpoint of health and physical fitness must be accomplished if progress is to be made and civilization advance. American public health leadership accepts, after more than seventy years of preparation, the challenge, and pledges its full resources and talents to the continued conquest of disease in our own country and abroad.

The Evolving Pattern of Tomorrow's Health

I. Prerequisites to Improved Public Health*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

Assistant Surgeon General, U. S. Public Health Service, Washington, D. C.

OBVIOUSLY, the first prerequisite to improvement of public health in any locality is a properly constituted health department. As quickly as possible, therefore, all areas and all population units should be provided with modern local health agencies directed by trained medical health officers.

In this undertaking, as well as in others to be discussed later, we shall probably be compelled to begin from a point considerably behind that which we had reached in 1940. That year will serve as a good point of reference, since it is the last year in which conditions were more or less normal.

Of the 3,070 counties in the continental United States, only 655 in 1940 had independent full-time health departments, and 356 had combined with adjoining counties to form local health districts. The remaining two-thirds were without formal health organizations under local auspices. As a rule, only those cities with populations approaching 100,000 employed full-time medical health officers and arranged their health services along modern lines.

Recognizing that the goals of public health cannot be attained through the 38,000-odd units which now make up the political mosaic of this country, the Subcommittee on Local Health Units of the Committee on Administrative Practice has suggested the grouping of counties and their contained municipalities in such a way as to derive 1,127 local jurisdictions. Wherever practicable, these units contain not less than 50,000 population, all of whom reside within 40 miles of the principal trading center of the area. Counties rather than state administrative districts were used in map making, since it was believed that the people to be served will wish to have a voice in the management of their institutions; consequently, they should also bear part of the financial burden.

To the more experienced and weather-beaten health administrators, such a scheme of redistricting may seem entirely visionary and beyond the realm of accomplishment. They know the difficulties inherent in bringing about and perpetuating effective working relationships between political bodies. In the future, however, funds for local health services are likely to be derived in greater measure from state and federal sources than has

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

heretofore been the case. With greater centralization of financing, the problem of amalgamation at the local level is certain to become less difficult. Either the scheme suggested by the subcommittee or some modification of it should be accepted by the professional groups without further delay, since plans for the future are dependent upon the establishment of rational service areas. In any event, the structures of state and federal health agencies will need to be strengthened so that they may be in position to supply certain specialized services beyond the resources of local jurisdictions.

When the full-time professional and technical personnel employed by health departments prior to the war are contrasted with the requirements of this proposed scheme of organization, approximately the following deficiencies are noted, despite the decreased number of local jurisdictions and consequent savings in personnel: physicians, 45 per cent; dentists, more than 90 per cent; engineers, 60 per cent; other sanitation personnel, 50 per cent; nurses (public health and visiting nurse services) 75 per cent; laboratory technicians, 45 per cent; and other professional personnel, about 50 per cent. Considerable reduction in these estimates, especially for nurses, could be effected by the employment of auxiliary personnel whose preparation need not be of professional grade. Nevertheless, such a reorganization would involve training programs that exceed present facilities. In addition, arrangements must be made for preparation of those representing normal replacements and of new recruits needed to fill the vacancies made by those who, for one reason or another, do not return after the war.

On the negative side, there seems little hope of attracting to public health work persons of the right types in numbers sufficient for future needs unless

provision is made for selection and promotion on a merit basis, together with reasonable compensation and retirement benefits. Despite innumerable present handicaps, states are rapidly developing their merit system rules and framework of organization. This plan needs to be extended to the local level. Mere installation of a merit system, however, is no guarantee of successful administration; unless the plan has the active support of the workers themselves, backed by their professional bodies, abuses are almost certain to creep in and discredit the system.

In the future, more attention must be given to the quarters health departments occupy. Common decency and self-respect require that health departments be taken out of basements of county court houses and condemned school buildings. The technical nature of those services that health departments will be expected to perform is a more compelling reason for providing proper surroundings and facilities for carrying on the work. Since the start in this direction will be made practically from scratch, we may assume that each of the 1,127 health departments will require a headquarters building costing at least \$75,000. Not fewer than two secondary health centers will be needed for most of the health jurisdictions. Each of these will cost as much as \$35,000, based on current construction prices.

Turning now to sanitation facilities, one still may find many needs that must be satisfied if public health is to go forward. Take, for example, public water supplies, one of the oldest and most fundamental of public health interests. It is estimated that 4,860 communities will need new public water supplies, and extension or improvement will be required for 6,450 of the present systems. Based on current costs, the new systems will entail an expenditure of \$180,000,000 and the exten-

sions and improvements, \$503,000,000.

Second in importance—and a close second at that—is the proper collection and disposal of sewage. A conservative estimate is that 7,690 communities will require new sewer systems and that 5,475 systems now functioning will need extension and repairs when construction can be resumed. The cost of such construction will probably approach \$605,000,000. Installation of new facilities for treatment of domestic sewage and industrial waste through municipal systems for about 10,500 communities and expansion of present facilities for another 2,000 are regarded as essential for safety. An expenditure of roughly \$1,380,000,000 will be needed to effect such improvements in community sanitation.

There are still approximately 4,000,000 rural homes that either have no excreta disposal facilities or are served by insanitary toilets. The estimated cost of providing the minimum accommodations, namely, sanitary privies, is \$140,000,000. Rural domestic water supplies, likewise, are far from satisfactory. About 3,600,000 rural homes are estimated to need new or improved supplies. The total cost of safeguarding this number of private rural water supplies would be about \$180,000,000.

With the type of industrial and agricultural economy prevailing in the continental United States, the hazards of insect-borne and parasitic diseases should be minimal if suitable provisions for necessary construction and maintenance were incorporated in programs of public work. Even malaria need no longer be tolerated. Blood surveys conducted around military establishments and war industries in malarious areas during the past year show the parasite index to be less than two-tenths of one per cent—the lowest on record. Furthermore, the disease is now perpetuated through a limited number of endemic foci. Barring the

introduction and establishment of new strains of the parasite or the occurrence of serious economic disturbance, competent malariologists believe a well directed program sustained over a period of not more than 10 years should achieve total eradication.

Altogether too little attention has been given by health officers to the changing pattern of disease incidence and to the possibilities for mass application of the newer diagnostic and therapeutic procedures. As a matter of fact, the whole group of acute communicable diseases toward which so much public health effort is directed accounts for less than 3 per cent of general mortality. While these diseases are important causes of morbidity among young children, they occupy a minor rôle as causes of industrial absenteeism. Furthermore, any review of the causes of general morbidity, physical impairment, or gross mortality clearly shows that the greatest advances in public health are to be made in the area of non-communicable illness. Many obstacles involving change in social attitudes, improvements in methods of finance, and relocation of both professional personnel and physical facilities must be recognized and surmounted before substantial progress can be expected.

Traditionally in this country, a man's illnesses have been regarded as his personal affair—something he may endure if he prefers, or from which he may obtain relief if he is both willing and financially able to do so. Gradually, as society has increased its investment in the training and security of the individual, this point of view has become a subject of serious debate. There are signs which clearly suggest that a complete reversal of attitude is in the offing. With such a shift in viewpoint, the means for implementing an enlarged program of medical care assume added importance.

Illness, by its very nature, is not adapted to individual financing. It is an experience not desired; hence most people do not have the incentive to provide for its consequences. Neither its occurrence nor its severity can be predicted for any one person. On the other hand, the illness experience for the nation as a whole, or for significant groups can be foretold with exactness. The costs, when apportioned, are not excessive for any but those in the very-low-income and dependency brackets.

Time will not permit, nor is this the occasion for discussing the relative merits of different schemes for distributing medical risks. Suffice it to say, however, that public health agencies—which presumably represent the consuming public and which are dedicated to raising the general level of health—cannot without losing their proper status refuse much longer to explore methods for extending medical service to all groups of the population. By this is not meant a mere academic or dilettante type of interest, but one that manifests itself in a desire for participation in actual organization and management of operating programs. Let us hope that the action this year of the Program Committee in devoting one general session to health insurance has set a precedent, and that future meetings of this Association may serve as forums for the discussion of proposed plans and accumulated experience in the general field of organized medical care.

Merely providing funds to pay for service, however, will not assure the delivery of medical care. This may be demonstrated today in almost any section of the country and particularly in the boom towns. People have the money to pay for medical care, but there are too few physicians, dentists, and nurses to provide the service.

Especially during recent years, phy-

sicians have tended to congregate in centers of population and wealth. Good roads and improved transportation facilities compensate only in part for reduction in the numbers of rural physicians. Expressed quantitatively, the problem is as follows: In states where less than 30 per cent of the population is concentrated in urban areas, there are available for service only 77 physicians per 100,000 persons; while in states where 70 per cent or more of the total population is classified as urban, there are 163 physicians for the same number of inhabitants. Influence of the economic factor upon availability of physicians is demonstrated by the presence of 147 physicians per 100,000 population in states where the per capita income exceeds \$600 as contrasted with 69 in those where the corresponding index of means is under \$300. In order to bring about an equitable distribution of physicians in relation to population, means must be devised for attracting to underprivileged areas not fewer than 25,000 physicians.

Among the disadvantages of rural areas that discourage the location of physicians is the inadequacy of hospitals and related facilities essential to the practice of modern medicine. For the nation as a whole there is a shortage of 166,000 general hospital beds. About 53,000 of these can be supplied through additions to existing institutions, but the remainder must be distributed among new hospitals, most of which should be located in areas away from the larger centers of population.

Fewer than one-third as many additional hospital beds are needed for tuberculous patients as for those with general illness. More than 50 per cent of the total number of new tuberculosis beds recommended are to meet deficits in the South. As in the case of general and tuberculosis hospital facilities, the southern states also have

extreme shortages in hospital beds for mental patients.

Provision of the required number of hospital beds of various medical types would involve construction costs of at least \$2,000,000,000. A building program of such proportions obviously cannot be undertaken in its entirety at any one time. Careful planning is called for if first needs are to be met first.

Now is the time to proceed with such details as site selection, fiscal arrangements, and the preparation of functional drawings for physical facilities of all types that serve the needs of sanitation and medical care. Without these, delay and confusion will follow later. Unless health departments bestir themselves in these respects, the greatest needs—especially in smaller cities and rural areas—may go unsatisfied even though there be a post-war construction program of large proportions.

With some variations among individuals, the problem of dental caries is practically universal. Yet all surveys emphasize the fact that only a minor fraction of the population receives anything approaching complete dental service. Two obstacles stand in the way of extension of dental service—inadequate numbers of dental personnel and prohibitive costs of care. Under the prevailing scheme of dental practice, from three to four times the present number of dentists would be required for complete dental service. Increased use of auxiliary dental personnel, working under the direction of dentists, would reduce considerably the number of dentists otherwise required and at the same time lessen the cost of care. By concentrating attention on the school age group and repairing carious surfaces as they develop, the consequences of neglect, namely tooth destruction, would be postponed at least to that time in life when the individual would be in a position to assume a larger measure of responsibility for his

own welfare. Despite the lowering of costs which could be achieved by procedures such as those suggested, many careful observers doubt that the problem of dental care can be solved without the development and widespread application of preventive measures which will materially reduce the incidence of caries.

After all the foregoing suggestions for preventing the occurrence of illness and increasing the availability of care have been put into operation, there will still remain even greater possibilities for advancing public health by means of research. Such research should be designed to elicit new and more effective preventive measures, to improve diagnostic and therapeutic procedures, and to lessen the costs thereof. Of course, the needs for and the possibilities in research are infinite, and no one can predict the applicability of any discovery regardless of how irrelevant it may appear at the time. From the standpoint of public health, probably the greatest needs for research are in the fields of mental disorders, acute upper respiratory infections, dental caries, and malnutrition.

Among the disease categories mentioned, mental disorders are outstanding. On any given day the number of persons in mental hospitals alone exceeds the number in general hospitals. Emotional maladjustments and mental aberrations of other types are present on all sides. Notwithstanding the extent of the problem, nowhere in the United States is there in operation a substantial, well conceived, and adequately financed program of basic research. The institutional care of the mentally afflicted is, and for a long time has been, the exclusive monopoly of public agencies; yet little has been revealed to reduce the problem or improve therapeutic procedures. This neglect constitutes a serious indictment of public medical service. Certainly

there is no basis for believing that mental abnormalities are inscrutable if approached through modern methods of research. Those disorders directly attributable to dietary deficiencies readily respond to improvement in nutrition. The malaria treatment of paresis is an example of what may be accomplished with the psychoses of infectious origin. Insulin and other forms of shock therapy indicate quite clearly that the deteriorative processes of schizophrenia and the melancholias can be stabilized and in some instances reversed. Because of its facilities for research and its responsibilities for the care of mental cases, perhaps the federal government should assume more aggressive leadership in this field. It has been suggested that the general pattern established by the National Cancer Institute be followed in projecting a program of research in the field of mental disorders.

In this country at least, man is fairly well protected against those infections he may acquire through ingestion, but no corresponding gains have been made against respiratory infections. Today the latter problem may be no more difficult than the former was some fifty years ago when the work started. With the extension of air conditioning, sterilization of the air we breathe—at least the indoor air which is most heavily laden with infectious material—may not be altogether visionary. A more satisfactory and universally applicable procedure would be some method of increasing human resistance to infection. Better therapeutic agents than those now available should lessen the amount of disability attributable, for example, to the common cold.

The third broad subject for inquiry considered as a prerequisite to improved public health is dental caries. Here is a field wide open for almost every type of investigation. The very few re-

search workers who have explored it are not in agreement as to whether caries results from a single or from many causes; whether the underlying factor is bacterial, chemical, or nutritional; or whether the condition represents some process in no way akin to any of these. As in the case of mental disorders, very little fundamental research is being done, and no program commensurate with the problem seems to be contemplated.

Fortunately, in the instance of dental caries, reliance need not be placed exclusively on the revelation of new facts which may disclose the intimate nature of the degenerative process. There are many possibilities in reparative dentistry that remain to be developed and exploited. Among these may be mentioned new synthetic fillings which would simplify the mechanical job involved and reduce the cost.

Basic research is needed to reveal the ultimate secrets of metabolism in order that efforts to influence body processes by food intake may be definitive. Of more immediate and practical importance are clinical and administrative studies designed to determine the rôle of health agencies in nutritional programs. So far agricultural agencies have carried the major share of the burden with little or no guidance from the medical and allied professions. This situation must be remedied if current information is to be applied understandingly.

SUMMARY

The present concern of all persons interested in public health should be: (1) to hold the gains already made in raising the general health level of the country; (2) to increase these gains by extending the traditional health services now in operation to all segments of the population; (3) to broaden the definition of public health service to include essential elements of general

medical care; and (4) to exploit the possibilities in research.

Several broad avenues of approach might be followed in translating this concern into action. National coverage by full-time health organization may be secured through reorganizing and combining existing health departments and establishing new units in areas where none now exist. Differences in opportunity for receipt of medical care can be corrected by removing economic barriers and by redistributing professional personnel and hospital facilities. Finally, public health should be significantly advanced by concentrating research activities upon the prevention and cure of mental disorders, acute

respiratory infections, and dental caries—diseases and disorders that contribute most to morbidity—and by improving our understanding of nutrition.

The Evolving Pattern of Tomorrow's Health

II. The Post-War City*

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A.

*Professor of Public Health, Yale School of Medicine, New Haven, Conn., and
Chairman, Committee on the Hygiene of Housing, American
Public Health Association*

THE usefulness and the importance of any profession in the social order rests upon the fidelity with which it holds fast to the sound and basic principles developed in the past and the vision with which it adapts those principles to the evolving challenges of the future. The American Public Health Association has an honorable record of more than sixty years of service; and at the end of this period we find a million lives a year being saved upon this continent through the control of tuberculosis, typhoid fever, and other communicable diseases and by the reduction of infant mortality. These results have been accomplished by the twofold approaches which together constitute the science of public health—the control of the environment of man by sanitary science and the upbuilding of the vital forces of man by preventive medicine.

The extent of our future usefulness depends on the degree in which we can apply these well tried principles to the tasks of tomorrow. Those tasks will no longer be concerned only with the negative problem of defense against specific killing diseases, but also with

the problem of upbuilding health and vigor and efficiency and the joy of living in a positive and creative sense. If we shrink from this challenge, public health will crystallize as a necessary but minor cog in the routine machinery of government. If we accept it, our leadership may be as outstanding in the next half-century as it has been in the last.

In a positive view of public health in the post-war period, the home and that aggregation of homes which we call a city must be of central interest. The home is the physical basis of the health of the individual. The city is the ecological background on which the physical and emotional and social soundness of a community depends.

The architect, with whom we must work in this field of the future, has not been slow to realize the intimacy of our relationship. Vitruvius in the first century, A.D., said, "The architect must know the art of medicine in its relation to the regions of the earth." Eliel Saarinen in his book on *The City, Its Growth, Its Decay, Its Future*, published this year, says, "It must be borne in mind that the family and its home are the cornerstones of society, and that man's physical and mental development depend largely upon the character of the environment in which

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

he is nurtured as a child, where he spends his manhood, and where he does his work."

It is on account of this intimate relation between the city and the health of its inhabitants that the Committee on the Hygiene of Housing was established by our Association six years ago. This committee has made substantial progress; but it has only just begun its task. We have prepared an outline of the Basic Principles of Healthful Housing which has been cordially accepted by experts in housing as the basis of their plans. We have ready for publication a series of inspection forms and appraisal procedures by which the degree of substandardness of individual dwellings, and of neighborhoods and areas can be determined with a high degree of quantitative accuracy. This procedure offers to the health officer an invaluable instrument for the exercise of his legal power of condemnation and his orders for the improvement of property. It should provide a sound basis for routine sanitary inspection, which in the past has not been one of the most efficient activities of the health department. It will be an inestimable aid in the programming of new housing developments and urban rehabilitation and in the wider reaches of city planning. The committee is now in position to render to health officers (at cost) the same sort of service in this field which the Committee on Administrative Practice has long provided in the general area of health department administrative procedure.

We are at present at work (with the aid of experts in administrative law) on a study of the legal bases of housing control, with special reference to the use of those delegated health department regulatory powers which have been employed with such notable success by Huntington Williams in Baltimore; and we have organized a special

group of expert subcommittees to translate our Basic Principles of Healthful Housing into specific standards to govern post-war home construction.

In all its activities, the Committee on the Hygiene of Housing has recognized that the individual home can only be improved and protected by considering it in relation to its environment. The contributions made by our federal and local Housing Authorities have had their chief significance in the fact that these authorities have created not only sound structures but sound neighborhoods; and our concept of the environment of the healthy individual as extending beyond the four walls of his dwelling must be projected to the city as a whole.

Our cities today are sick; they suffer from the chronic and progressive slum disease. It is no mere figure of speech when we talk of "blighted areas." "Blight" in a city is like blight in a plant or cancer in the human body. It spreads from its center year by year as Howard Green's maps of Cleveland show so clearly. Our cities are decaying at the core; and, in a vicious circle, the taxable values which are needed for rehabilitation are escaping to governmental areas outside the municipal limits. The situation is serious; and the treatment must be radical.

The essential needs which must be met in planning for a healthful city are many. We may enumerate some of the most significant of them:

1. A location for the city in a region where climatic conditions are favorable. No civilization can develop greatness where the climate is too far from a desirable mean.

2. Access to primary sources of food supply. The students of geo-politics are right in their emphasis on the relation of the heartlands and the coastlands; and the strength of the United States is largely due to the fact that it—alone of all the great continental

powers—controls both types of area under a single flag.

3. Adequate and safe water supply. The presence of a spring or well was generally the determining factor in the choice of the site on which a village grew into a city (Blackstone's spring on Beacon Hill in Boston).

4. Sanitation, including particularly protection against vermin which play a rôle in the spread of epidemic disease. The first settlement at Jamestown, Va., had to be abandoned on account of malaria.

5. Protection against enemies. The hill cities of Italy and of early New England were placed on the heights for protection against both malaria and human foes. If we do not combine on a world-wide basis to chain the dogs of war, the hazard of the bomber will be a determining factor in city planning. The dangers of automobile traffic must certainly be an essential factor in such planning.

6. Illumination. The practice of street lighting (first it is said, introduced at Antioch) has been an essential factor in making the growth of the modern city possible.

7. Housing. Most vital of all the elements in a modern city is its housing. To quote again from Saarinen, "The primary purpose of the city is to provide adequate living and working accommodations for its population."

8. Transportation. Convenient circulation between various points in the city and easy access to neighboring communities is obviously essential to sound municipal development. Waterways determined the site of most of our cities. The railroad and the automobile have dictated the lines of their recent evolution. The airplane will profoundly modify their future.

9. Means of livelihood. The health of the city must basically depend on the factories and the fields from which its residents and the environment to

which it furnishes trading facilities procure their livelihood. Many of the new industrial communities developed in the present war emergency will form the centers of new permanent civic areas.

10. Recreation. In the future economy of plenty to which we look forward, it will be increasingly clear that man works to live and does not merely live to work. The shortening of the hours of labor and the years of labor will make leisure time activities of increasing significance as the world of the future is evolved.

11. Facilities for trading. It is too often forgotten that the commercial district of a city is quite as important an element in its prosperity as its industrial development. In cities serving adjacent rural areas, the factor of commerce may be more important than that of industry.

12. Social intercourse. The country store and the market place have served an essential rôle as centers of neighborhood and civic interest. This will be a function of primary interest in planning the city of the future.

13. The school. The little red school house—in its more modern and effective forms—must always be an essential element in healthy community life.

14. The church. The white steeple among the elm trees is the most characteristic symbol of the New England village. The element of community worship meets fundamental human needs which can never be outmoded.

The relative emphasis on these various fundamental needs of community living will vary with the progress of mankind. The half-timbered houses of the medieval town clustered about the cathedral on the hilltop. The baroque city spread itself along broad avenues radiating from the palace of the King. The industrial metropolis of today huddles about the factory. I have sometimes dreamed that the central feature

of the city of the future will be its churches and schools, its playgrounds and its recreation centers, with the fulness of realization of the human personality as its keynote, rather than the dominance of bishop or king or production manager.

Whatever the dominant motif of the city of tomorrow must be, it is clear that such a city must be developed as a whole, with unity, with purpose, as a total expression of the spiritual ideals of its people. The cathedral city and the palace city had a measure of such unity; and they were beautiful places to see, satisfying places in which to live. The industrial city of today has no such unity and no such significance. It is not a healthy biological development but a diseased product of fortuitous and unregulated economic forces. If our civilization is to be worth saving, its cities—and much of its countryside as well—must be rebuilt more nearly according to our heart's desire.

We come then to planning—the deliberate and purposeful and intelligent application of the human mind and the human will—as the only possible solution of our problem. We must plan the homes of the future in the setting of neighborhoods, neighborhoods in the setting of cities, cities in the setting of regional areas, of nations and of the world economy.

For each area we need a master plan drawn up in consideration of the probable population of that area, its industrial and commercial and agricultural future (in the light of its relation to the outside world); a physical plan which will provide for the roads and streets and utilities, for industrial and commercial centers, for recreation areas and for homes; a social and economic plan which must form the basis for physical development; with appropriate legal and fiscal policies for the execution of the program.

The time for such planning is today;

and the difficulties and complexities of the problem need not deter a people like ours with three centuries of pioneering tradition in our blood. That the end sought is not an academic dream may be indicated by a recent contribution—on one phase of the problem—by the U. S. Chamber of Commerce under the title “Plan Now for Future Public works.” This document points out that—

“In New England, the exercise of foresight would be termed ‘Yankee shrewdness,’ in the mountains of the South it would be ‘gumption,’ in the West ‘horse sense.’ Wherever found and whenever used, it is merely the application of good common sense in our affairs, personal and public, local and national.

“We all remember vividly the great depression which followed the roaring twenties. Men out of work, apples sold on the streets, bread lines, relief headquarters with interminable lines of applicants, poverty and destitution. It was not a pretty picture. We do not want to see it occur again.

“Good common sense should tell us that if we intend to avoid a repetition of this ugly picture, now is none too soon to do the real hard spade-work necessary for its avoidance. That means ‘Postwar Planning.’”

We are all, probably, in favor of planning in some form or other; but when it comes to the question who is to do the planning, harmony dissolves into discord. Big business is all for planning, by big business—but not by government. Republicans are all for planning, by Republicans—but not by Democrats. Governors are all for planning, by the state—but not by the federal government. President Wriston of Brown University says in the August *Harper's* that “Government by bureaucracy, control of business by administrative regulation, manipulation of the economy for political purposes—

these are stark reaction." Representative Sumners of Texas, in the September *Reader's Digest* thinks we are on the road to Hitler totalitarianism, and his remedy is to "send all these non-federal functions back where they belong to the states and the local communities." Yet it is clearly impossible for business to plan with intelligence except in relation to governmental plans, or to prepare local and state programs except within the framework of a national plan, or to make any plan at all without "administrative regulations" and "manipulation of the economy for political purposes"—if we assume that the word "political" is used in its true meaning as "pertaining to polity, or politics, or the conduct of government . . . relating to the management of the affairs of state."

One of the most unfortunate examples of extreme opposition to the intelligent exercise of foresight was the action of our last Congress with regard to the report of the National Resources Planning Board. This report is recognized by all competent critics as a technically sound and philosophically illuminating document—far more significant for the United States than was the Beveridge Report for Great Britain. Yet the Beveridge report was on the counters of all the New York bookstores last December, while the National Resources Planning Board report has been—for the time being—smothered and ignored. Congress not only abolished the Planning Board, as a part of its private war against the administrative branch of the government, but provided specifically that no other agency of that government should continue any of the work of the Planning Board and that the records of the board should be kept in the archives and not made available to any other government agency.

The argument against planning by governmental agencies—the only agencies which can possibly plan in the

common interest of all of us—always follows the same general line. It relies on an emotional appeal against "bureaucracy" and an invocation of the sacred rights of the individual, which are supposed to be threatened by collective action. It ultimately stems from the doctrine of laissez-faire the mystical creed that if you let everything alone and everyone does as he pleases, some hidden god-in-the-machine will make everything come out well.

Yet it should be abundantly clear that there is no fundamental opposition between individual action and group action, that individualism is not always desirable and collectivism always undesirable. Our objective in a democratic society must, of course, always be the integrity and the welfare of the individual. It is equally certain that the welfare of the individual can often only be attained by collective action. In the field of housing and city planning, for example, it is clear that unregulated individual initiative has created our inflated urban land values, our ghastly slums and our decaying cities. The only possible way out is far-sighted and intelligent planning—not of boulevards and civic centers, primarily—but of communities, in which the individual can live and work and play and develop the fullness of his personality. The same need for planning is obvious in the social and economic spheres, where the individual needs the strength gained by collective action in order to attain the opportunity to work productively, to secure the medical care which has never been adequately provided for low income levels in the United States, to obtain a reasonable degree of protection against the unpredictable hazards of illness and old age—all of which desiderata are essential to the realization of that "dignity of the individual" of which we have talked so eloquently.

The problems involved are complex

ones. They must be decided by the people for themselves; but that decision must be made with the aid of expert advice. I suspect the most individualistic pioneer when he sought a path through the forest did not ignore the evidence of a trail made by some predecessor. Such a trail is a "plan" and the planner is essentially a trained and experienced trail-maker. This is why the indiscriminate abuse of "bureaucrats" is a particularly unfortunate manifestation of the effort to arouse irrational passions. Who are the "bureaucrats" of the United States? They are the hired men you and I employ to do some joint jobs for us. Is the postman who delivers your letters a "bureaucrat"? Is the traffic officer on the corner a "bureaucrat"? The chemist in the Department of Agriculture improving fertilizers; the physician in the U. S. Public Health Service controlling epidemic disease; the actuary administering the Social Security legislation passed by our Congress; even the harassed men and women engaged in the enforcement of essential wartime legislation; are these all "bureaucrats" because they happen to be hired by us to work for us, not by a private corporation to work for it?

The health officer is one of those dangerous "bureaucrats" who is striving with unselfish devotion for the common good; and one of the urgent

demands upon him in the future years will be for participation in the salvation and the upbuilding of the cities of this American continent. This is a task in which he must share—for the basic ideals involved in city planning are health ideals, if we think of health in its broader sense. It was not a planner or an architect who has given us our most vivid word-picture of the essential significance of the civic ideal. It was a great health officer, Sir George Newman, who said:

"What a strange and mysterious thing is a city! It is both a dream and a reality, a past and a present, the houses, workshops, and shrines of a commonwealth. It is the hearthstone of the people from which they measure the world. It is their dwelling place, the cradle of the living and the sepulcher of the dead, a home in the minds of men where their glory remains; an unseen army coming in through the Eastern portals of birth, an unseen army passing forth through the Horn Gate and Golden Gate and the gates of the West. It is the embodiment of the arts and crafts of man, the mart and market place of his merchandise, his rear guard from the enemy and his hiding place from the tempest, the beginning and end of the work of his hands. For men make cities, and cities make men; 'the walls of our cities are men.'"

The Evolving Pattern of Tomorrow's Health

III. The Health Department of the Future*

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A.

Dean, School of Public Health, University of Michigan, Ann Arbor, Mich.

THE preservation of public health has long been recognized as the first obligation of government. In the absence of health, man cannot survive.

Shed of the garb of superstition steeped in the fear and emotionalism of the miasmatic and epidemic constitution era, public health practice must now stand on its ability to provide people with the privileges of a long and healthful life which today's science and community health service can now provide. The dread of catastrophe with the approach of some devastating plague of unknown cause compelled people to place faith and authority in committees and boards of health. The healthmen have performed in noteworthy fashion in controlling epidemic disease and in sanitating man's environment. The pandemics of yesteryears are largely gone. The maintenance of communicable disease control services and supervision of water, milk, food, and excreta disposal can keep epidemics at a respectable distance. The modern health department must do more than reminisce on the visitation of smallpox, yellow fever, cholera, and the plague. It must contribute to the fulness and wholesomeness of a protected life.

The health department of the future must concern itself with the broader

interests of the masses. Education has dissipated the mysticism of medical practice concealed in a terminology of the classics. It has brought forth the realization that the eternal fight for good health is a people's struggle against ignorance, superstition, and poverty. The newer knowledge of the causes and modes of transmission of disease have dispelled the urge for the philosophic conjuration of the appointed few, and autocratic direction of the official healthman. Now the mother in the slums understands more fully than her sister on the broad boulevard the value of a safe milk and a sanitary food supply as a protection against the enteric diseases. The advantages of good medical care, of hospitals, diagnostic, x-ray, laboratory, and other technical services are now understood, and the urge to have them at the time of need is becoming universal. People are no longer satisfied with a barrier against the occasional epidemic; they seek the daily satisfactions of a vigorous and buoyant health. It is the healthman who has created these demands and appreciations. It is he who must see that the needs of the future are met on broad community bases.

Total health planning for the people of any area necessitates a complete knowledge of all groups and factors which contribute to better care both in health and sickness. Does the health officer consider community facilities in

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

relation to his population, area, transportation, special needs, and the economic capacity of his people? Is the number of practising physicians, dentists, and nurses adequate to meet local need? What of the general hospitals, their character, standards of practice, availability of beds, costs of service? In what manner are adequate facilities and services provided for the indigent and part-pay patients? The benefits of good bedside nursing service have been broadcast without limit. Is such service now available to all who need it irrespective of their ability to meet the cost with family funds? And what of the clinical and public health laboratories? Are they licensed or controlled with a view of assuring good quality of service? Are blood counts, urine analyses, basal metabolisms, x-ray examinations within the price range of the many or available only to the few? Are the services of the competent pathologist and roentgenologist provided for expert and understanding interpretation of results? How long does it take to secure the examination of a sample of water or milk? Is blood plasma making its contribution to civilian defense? Does the community possess its own blood plasma reserves, in hospitals or state-wide pools, from which local physicians may obtain free plasma for treatment of patients in their charge? What types of medical and dental services for indigent and low-income groups are available in the health area? How are drugs, appliances, glasses, dentures secured? These and many similar questions must be answered by the health officer before he can proceed to a definition of his problems, problems based upon mortality and morbidity statistics, and an analysis of available service records by area, racial and social groups.

In dealing with the communicable diseases including tuberculosis, syphilis, and gonorrhea, the public health ad-

ministrator has not restricted his activities to statistics and health education. He has dealt with diagnostic facilities, consultation service, x-rays, laboratory service, tuberculin testing, blood examinations. He has been concerned with the adequacy of medical and nursing care, in sanatoria and hospitals, in clinics, and at home. Prompt and adequate care is essential to patient recovery, rehabilitation, and the control of infection. The health officer will extend his interests beyond the realm of the communicable diseases and plan community-wide programs to deal with other causes of disability—the problems of the adult, the aged, the industrially employed, accidents in the home, at work, and elsewhere. To what extent are those employed by tax supported agencies, by industry or commerce, or by other organized groups provided with hospital, surgical and medical care on an insurance basis? To what degree are industrial hygiene services available in the health area? What of plant sanitation, water supply, waste disposal, safety and wholesomeness of food served? What are the major industrial health problems and what is done about them? These and many similar questions must be answered by the health officer in evaluating the completeness of his community program.

The modern health department must assure to all the people the advantages of freedom from lingering illness and early death. We know a great deal about the character and manner of handling most diseases. We are wanting in the machinery with which to make medical, dental, nursing, and other public health services readily available to the masses. It does not follow that the health officer should of necessity administer all the functions and activities which we have enumerated. As a rule he will not. These services will not all be a part of the

health department fabric. The form of organization will vary with time and place. It is, however, essential that the health administrator become a leader in the planning and a coordinator in the fulfillment of such programs even though they be not under his direct administrative supervision. Should he fail to become a leader in a new health era of tomorrow, others less competent stand ready to act in his stead.

There has been much waste of personnel, time, and material, in the name of public health. In the days of inexact and partial knowledge of the causative factors of disease spread, there was some excuse for this waste. But even today many health departments emphasize the esthetic and the politic at the expense of the fundamental principles of health promotion. In the emotional and terrifying days of yellow fever, cholera, and other exotic diseases, the judgment of the health committee was seldom challenged. Any expenditure of public funds or any imposition on personal liberty seemed justified as a public health measure. Today with a more common understanding of disease control and prevention the board of health must give full and reasonable accounting for all of its costs and expenditures. To do otherwise means loss of public confidence and willingness to support the work of the health department. Appropriations would shrivel up and soon disappear if the people did not give understanding approval to the health program. We can find comfort and aid in our own *Evaluation Schedule* for local health services initiated by the Committee on Administrative Practice in 1921, repeatedly revised and adjusted during the past twenty years and kept attuned to the ever-changing concept of health needs, and now streamlined to meet the social, health, and welfare problems of the future. Together with the new *Evaluation Schedule* there is now being pub-

lished a *Guide* to serve as an administrative handbook. There has also been published a booklet known as *Health Practice Indices*, consisting of a series of charts showing the range of unit practice for cities and counties which have submitted schedules for the past two years. It is believed that this pamphlet will serve a most useful reference purpose to health officers as it will depict practices in various parts of the country. These three publications constitute the measuring rods with which the health officer may study his own work and accomplishments in relation to the work of others and in terms of group judgment as expressed by the members of the Committee on Administrative Practice.

Our existing trained personnel of physicians, dentists, public health engineers, nurses, and others who have prepared for a professional career in our field of life conservation have not been effectively employed to secure complete and adequate coverage throughout the states. Until the release of the report of the Subcommittee on Local Health Units no master plan had been prepared for the extension of full-time local health service to all parts of the United States. This committee has shown that there are 41,052,600 persons in 1,687 counties in 41 states for whom no full-time health service has been provided, while in the remaining counties, cities, and districts there is frequently found duplication of effort by political units. It is now believed that 1,127 local units administered by a professionally trained and experienced health officer, preferably a physician with appropriate associated professional and technical personnel and equipment, can provide the quality and quantity of health service suggested in the *Evaluation Schedule* and its accompanying *Guide*. As a rule (and we admit an occasional exception to any man-made rule) population units of less

than 50,000 are not able to obtain and support well qualified personnel, and find it difficult to support a full-time local health unit. A balanced program demands an adequacy of trained personnel in addition to the medical officer of health. Minimum ratios have been suggested for public health nurses (one to each 5,000 population), public health engineers and environmental sanitarians (one to 25,000 population), clerical personnel (one to 15,000 population). The committee has under consideration the need for health educators, statisticians, and laboratorians.

The committee's proposals do not, however, end here. They include economic and professional service factors. It is stated that:

... in developing district outlines an endeavor should be made so to group counties or parts of counties as to reduce large inequalities in per capita income by combining urban and rural, high and low income groups in a single jurisdiction where otherwise desirable. Also, in combining counties or parts of counties within one district an attempt should be made to group them so that the ratio of physicians will not be less than 1 to 1,500 of the population, and that the general hospital beds available for the community be not less than 3 per 1,000 of the population.

All these recommendations suggest new responsibilities for the public health administrator. Neither self imposed isolation in the seclusion and comfort of a city hall chair nor complacent meditation on the occasional epidemic and abatement of nuisances offensive to the olfactory nerve will produce the type of community-wide understanding and coöperation so essential to the fulfillment of the health program. The health officer must become a leader among the professional and lay interests of his city, county, or district. He must elevate his office and influence from the era of the garbage dump and pesthouse to leadership in education and in the social, health, and welfare services. Health education is

the foundation upon which all public health practices survive. And there is no need of giving the public the newer knowledge essential to health promotion unless we provide the facilities to make the services universally available. There is no need to excite people about the ravages of syphilis or the devastating influence of tuberculosis unless we prepare and establish the facilities through which the individual may receive the benefits which are his due. Why sing the praises of penicillin, the sulfa drugs, or blood plasma if these are not within the financial reach of the individual? Every new health promoting and lifesaving activity should be available to all alike, as rapidly as such developments are scientifically approved and commercially practical. To teach people what they should have for sickness and health, be it food or medicine, and then fail administratively to make accomplishment possible results in frustration, disappointment, and social unrest.

For the public health of the future we need democratic planning and participation rather than autocratic dictation by government or vested interests or fortified minorities. The newer knowledge of the medical sciences is making available a great host of lifesaving drugs, sera, preventive and protective treatments. The discovery and use of many of these substances has been stimulated by the war. New problems in distant lands, the want of therapeutic preparations of prewar days have prompted the development of new and substitute means of handling disease and promoting health. Their value will be well known to the returning members of the armed forces. Demand for their use will be universal. Programs for community health service must include all these implements for warfare against disease. It means better health departments, better medical and dental services, hospitalization

when indicated, the means of early diagnosis, laboratories, x-ray services—all within the means of every one of us. The health officer of yesterday must

unshackle himself from the dogmas and heritage of his predecessor and become a leader of the new public health of tomorrow.

Maternal Mortality in New York State: 1933-1942

... Ten years ago the New York Academy of Medicine published the findings of its Committee on Public Health Relations based on a study of more than two thousand deaths from diseases and conditions associated with childbirth.* In introducing this courageous report, the Committee observed that "the spectacular progress of the last years in the reductions of many death rates has not been paralleled by any drop in the rate of death from puerperal causes." Its unequivocal conclusion was that as a conservative estimate almost two-thirds of the deaths were preventable, "that number of women, if they had had proper treatment and care, could and should have been brought safely through parturition." The responsibility was divided by the Committee in an almost 2 to 1 ratio between the attending physicians and patients: the physicians were charged in equal numbers with error of judgment or error in technique; the patients, with failure to obtain suitable care (59 per cent), or lack of co-operation (41 per cent).

The disclosures made by this distinguished body of specialists, their concrete recommendations, the probing activities by other medical groups throughout the State, which brought about radical changes in obstetrical practice and hospital procedures, and the coincident developments in chemotherapy have produced astonishing results. Now the sentence quoted above may be justly inverted: "the spectacular progress of the last years in the reduction of the death rate from puerperal causes has not been paralleled by the drop in the rates of death from most of the other important causes." The Committee considered that it should have been possible to prevent 65.8 per cent of the maternal deaths. In 1933 the New York State rate was 63 per 10,000 live and still births; in 1942 the rate was 22, a reduction of 65.1 per cent! This almost perfect correspondence between scientific hypothesis and actuality, while striking, would be unimportant did not the present favorable condition represent a stage in an uninterrupted downward trend.—From *Health News* (New York State Dept. of Health), 20, 42 (Oct. 18), 1943.

The Evolving Pattern of Tomorrow's Health

IV. The Health Worker of the Future*

REGINALD M. ATWATER, M.D., F.A.P.H.A.

Executive Secretary, American Public Health Association, New York, N. Y.

THE other day a well known commentator on current affairs who was predicting the pattern of post-war America went out of his way to assure his readers that the quality and quantity of public health services were sure to be expanded and increased. Such an idea probably never occurred to the commentators who were forecasting the brave new world a generation ago, and indeed the fact that anyone may so predict with confidence now throws light on what has happened in the last quarter century. Commentators may now have before them forecasts like Dr. Vaughan's of the health department of the future around which to imagine the reality of community health.

The health worker who was preparing himself for career service in public health 25 years ago had a difficult task because, for one thing, the classes of public health workers were not sharply defined, their titles and functions had not become at all uniform, and there was slight tendency through the development of merit systems and other devices to bring these functions down to a common level in the various parts of the country. In short, the progress

toward making public health a profession had just begun, and it has been allowed to grow since without much conscious planning.

To those who have grown up into careers in public health during this quarter century these facts are familiar, yet it probably is well for us to remind ourselves of such significant changes as we try to look ahead to the post-war period and to forecast something of the character of the health worker of the future and his place in the community. We shall assume that his undergraduate training will continue to improve; we shall concern ourselves with graduate levels of training and experience.

This effort to sketch a composite picture was suggested by the Program Committee in planning the 72nd Annual Meeting, and William P. Shepard, M.D., Chairman of the Committee on Professional Education, was chosen as the person best able to look ahead. Dr. Shepard's inability himself to be present need not prevent his contribution to the thought and planning which are here reflected, for it is in this field that his committee has been laying a foundation. The work of the Committee on Professional Education now represents 13 years of consistent study and planning on the part of a specially selected group who have sought to make a true forecast of the health worker that

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

is to be. This committee was organized under the Chairmanship of W. S. Leathers, M.D., who, four years ago, was succeeded by Dr. Shepard.

We may today think of at least 22 specialties comprehended within the framework of public health. Besides the better recognized classes, such as health officers, public health engineers, sanitarians, public health nurses, laboratory directors, vital statisticians, industrial hygienists, nutrition workers, maternal and child health workers, epidemiologists, and school health men, one may list the public health dentist, the food chemist, the serologist, the pathologist, the bacteriologist, the medical specialist in tuberculosis, syphilis and gonorrhea, the medical administrator, the executive of voluntary health agencies, and perhaps a dozen other specialties which have grown up during the rapid development of professional work.

You have heard Dr. Vaughan say that the modern health department must do more than reminisce on the visitation of smallpox, yellow fever, cholera, and the plague. It must contribute to the fullness and wholesomeness of a protected life. Fortunately Dr. Vaughan is a member of the Committee on Professional Education, through which the Association is helping to prepare the human material upon which his plans for better health departments must directly depend. It is appropriate therefore for this forecast to be read in connection with Dr. Vaughan's brilliant paper on the task which the health worker will have to perform.

QUALITIES OF THE PERSON HIMSELF

This forecast assumes that the person himself will possess qualities which enable him to be above the average in capacities which we all recognize as useful to career men and women. I am impressed that knowledge of public administration and of public law will give

any health worker an advantage as he builds a career. There are, of course, other universally recognized subjects of importance. Especially will he do well to possess information about good personnel administration, whether he be employer or employee. We can expect the significant advances here of which business has already availed itself to be used in public service as well. The career healthman needs the fundamental information usually comprehended in systematic courses, but he also needs training and experience in the use of these tools in real life so that, in Browning's phrase, he will "watch the master work . . . and catch hints of the proper craft, tricks of the tool's true play."

What an advantage any person has who possesses public speaking ability, with poise before an audience and the ability to use his voice effectively. Similar ability in writing will represent perhaps an even more important resource for the health worker of the future than today. These skills may be acquired like others. It is encouraging to see the recognition of these values among the schools of public health. One school has set itself to make a recording of the voice and the public address of each student as a base line from which improvement may be expected. Another proposes to make good attainment in English composition a requirement. All of this will tend to make the healthman a more outgoing person, better able to transmit to others the knowledge and the attitudes which he possesses, and more persuasive in his approach. He must be more articulate. Is it not regrettable that our professional courses today tend to squeeze out of the trainee all the extroversion that he may have possessed? It results in the present difficulty to find even a few good public spokesmen among professional persons for radio programs of national scope. Yet I be-

lieve that the native endowment of public health workers in such ability is probably equal to that of those going into law or the ministry. The value of these accomplishments needs to be recognized and encouraged in our formal curricula so that the candidate will be both well informed and a real person. And we must encourage better performance, preferably by good example.

The inquisitive mind is another possession which we should like our public health worker of the future to possess, and we hope that he will carry on with such an attitude after his formal courses and into his daily life. Post-graduate training, in-service training, and refresher courses will mean much more to him and to those he serves if such a youthful freshness of viewpoint can be maintained and encouraged by the framework which we create for his employment.

IMPORTANT FOUNDATION STONES FOR A CAREER

Among several subjects which the worker of the future should understand I would like to emphasize a familiarity with social welfare and the economics of health. He should be conversant with the problems of public medical care and will probably more nearly accept than his colleagues of today the philosophy which the Association has declared in its official memorandum on "Desirable Minimum Functions and Organization Principles for Health Activities."¹ The teaching institutions must lead the way and prepare the student to expect a better pattern than that of the status quo.

It seems likely that the formal curricula for those preparing for life service in our field should be planned and operated by the universities, and that governmental supervision should not be expected to reduce these to a single denominator. We shall not soon be ready for rigid uniformity in this re-

spect, yet there is a need already apparent for certain standards in the training of students, and the memorandum recently published by the Committee on Professional Education represents a declaration which forecasts some desirable minima which may by reference be included here.² The time is here, however, when the trainee has a right to know whether the school which he selects meets reasonable standards in its equipment and personnel. It is my belief that a listing of acceptable courses in public health is a need which now should be met and that the proper agency to list courses, outside of those in public health nursing, is the A.P.H.A.

There will follow a need for recognition of the attainment of the worker himself. There may be need for some certification beyond that afforded by Fellowship in the American Public Health Association and by the specialty diplomas now in use. It is my opinion, however, that the solution does not lie in an extension into public health specialties of the specialty board system which has grown so rapidly during the last decade in medicine.

PATTERN OF PUBLIC EMPLOYMENT

What may the worker of the future expect that pattern of his public employment to be? I believe that he can expect an expanding demand for this service and a readiness on the part of the public to pay salaries more nearly equal to those of his peers in his own profession and that of teaching. Certainly he can expect further progress to be made toward public service as a public trust, the trend toward which is already discernible in some political units. The recent amendments to the Social Security Act in the United States have given a substantial momentum to these changes and, if they are wisely administered both nationally and locally, it seems possible by this means to do away with the spoils system as it still

involves some health departments. Let no one underestimate the difficulty of this achievement, yet the way has been shown in some outstanding agencies and the future does belong to those who succeed in making public health a career service with at least as much independence as public education now possesses. Of basic importance to this end is the attitude of the public health professions toward the merit system, and at this critical point the American Public Health Association proposes to help make merit systems better and to create among the public health professions a sound appreciation of their significance.

Public merit systems, operated as a part of modern personnel management, seem to be clearly in sight. The good effect of such progress can hardly be measured on the attractiveness of professional work under public auspices, for the climate can be changed for the better and public employment may well attract and challenge the best personalities of the oncoming generations. It will take time to remove the incubus of old fashioned civil service systems which have bogged down with accumulated routines not at all acceptable to well trained career persons. The concept of civil service as a room, with a heavily guarded entrance and a barricaded exit, and with nothing between, represents an outmoded pattern. With an up-to-date recruiting system, with good job classification, with modern, objective examination methods, with personal service ratings, in-service training, a good salary system, supervised promotion, and with workable methods of separation from the service, the health worker of the future can well expect to live in a climate where the best he has to give may be given under circumstances that encourage career service. The Association hopes that such an achievement may be reached through coöperative planning between

its Committees on Administrative Practice and Professional Education. The latter committee now has a staff at work productively along these lines.

A PROGRESS REPORT

Such a statement of ideals for the future requires that we orient ourselves as to the progress already made toward these goals. The 13 years of the Committee on Professional Education have resulted in the formulation of eleven statements regularly adopted by the Association, covering the educational and experience qualifications of as many specialties. In addition, four reports are in various stages of completeness as they progress through a regularly established routine of the Committee on Professional Education. Within another year it is not too much to hope that the Association will have reports available covering the best present opinion on training and experience on practically all the specialties represented in public health. A well planned scheme of periodic revision will serve to keep these statements fresh and abreast of the best thought as the years pass. The present circulation of reprinted reports has now exceeded 16,000. Thus the high aims of the founders of the Committee on Professional Education approach fulfillment and the worker of the future will owe much to these formulations of the most reliable opinion available. They are not static formulations, neither are they laws, but their influence is extending daily, and already they have been reflected in the qualifications required in scores of state and local jurisdictions and, with the progress of the Merit System Unit, it will not be long until they will have a really profound effect on professional levels throughout the United States and its possessions.

There is no intent on the part of the Association to ignore the voluntary agency and its staff in these considera-

tions which, for good reason, are focused largely on the official agency. There will probably continue to be many such privately employed persons. We shall hope to have a much more adequate forecast of what voluntary health work of the future will be like when the report now in preparation by the National Health Council is published. Even now, however, the Committee on Professional Education has reports in process or approved which relate directly to these unofficial activities. After all, a specialist—shall we say in tuberculosis—needs a background much the same whether he shall serve this year in a public agency or next year with a private group.

In the early stages of the development of professional standards it is inevitable that there should be rather sweeping exceptions allowed on account of those who had attained more or less standing before the movement upward got under way. Just as in the standards for admission to medical practice there had to be a "grandfather clause" to take care of those who had enjoyed years of practice before the rules came into effect, so it has been necessary in public health specialties to make similar provisions. The day is coming, however, when the passing of time will make such exceptions needless, and the occasion for recognizing unprepared persons appointed for political or personal reasons will become rare. The net effect of this progress on career service in public health will be good and far reaching.

The stimulating experience which has come to universities and to hospital staffs through the exchange of visiting experts should now be arranged by staffs of health departments and of other agencies. Why should not a plan for the loan and exchange of valuable staff educators, for instance, between university departments of nursing and visiting nurse associations, be now

within reach? A comprehensive plan for field training centers open to those who complete the academic courses is imperative. If these can be set up co-operatively between several universities and local health agencies they will have an even greater usefulness. Such cross-fertilization as in these exchanges and in coöperative field training can make the service of the health worker of the future a stimulating and delightful experience that can stand in contrast with deadly routine which so easily develops where imagination and freshness are lacking. This plan can readily be worked in with present plans for study leaves, and can push forward the average of staff understanding and performance without waiting for another generation to arrive.

RECOMMENDED ACTION

This attempt to sketch a composite picture of the health worker of the future assumes that the teamwork which at best now characterizes some official and some private agencies will be attained elsewhere. Patterns of action which reflect this teamwork between federal and state agencies and between official and nonofficial may be cited. The present method of lend-lease personnel by the U. S. Public Health Service, together with in-service courses, has done something to promote higher standards everywhere. The present coöperation between the federal and state official agencies and the Merit System Unit of the A.P.H.A. makes it possible soon to expect the day when good methods of personnel administration will be available in every state. There are hopeful signs that the person trained and experienced in one section of North America may be useful and available for other areas through common registers. The preparation by the professional society of standard reports on communicable disease control, on the examination of water and

sewage (in coöperation with other agencies), on dairy products, and on diagnostic procedures—are serving a useful purpose in raising levels of work and eliminating meaningless differences. Thus blind alleys in professional advancement can be obliterated and ability can be better recognized wherever it may appear.

We have said that the developments of the last quarter century have been important but largely unguided. What may we do now to make career positions more attractive and more productive after another 25 years? What can a professional society do to guide the developments of the future?

We certainly should encourage the systematic training of those persons who have proved themselves to have ability. I believe the future will approve an apprentice system of testing trainees before postgraduate courses.

We should create a desire among health workers as among the public for modern personnel management, including merit systems.

We must encourage the better students in our undergraduate levels to seek careers in public health.

We must set before the oncoming generation good examples of public service which in turn will make profound differences in the health of our grandchildren.

We must make the public aware that in this field we are in competition economically with careers that offer good money returns and that, in the long run, there is no sound economy in low salaries and all that they bring.

I believe that Dr. Shepard and his committee have laid a durable founda-

tion for the professional worker of the future and that the pattern for 1968 can be discerned in what we have now at our best.

The post-war world is going to need public health more than ever before. We have a growing tradition here that can be of high value for North America and perhaps good enough and strong enough to share with the rest of the world.

At any rate we may be sure that careers in public health founded on public service as a motive will bring that prestige which we seek for the healthman of the future and that there is no other way. Then advancement and recognition will properly come to those who have given most liberally of themselves to others.

"Oh if we draw a circle premature,
Heedless of far gain,
Greedy for quick returns of profit, Sure
Bad is our bargain!"

Dr. Vaughan has said that the health worker of yesterday must unshackle himself from the dogmas and heritage of his predecessors and become a leader of the new public health of tomorrow. Somehow I have confidence that through the American Public Health Association we are accelerating this process.

Function of the Health Officer in the Control of Tuberculosis among Veterans*

LOUIS I. DUBLIN, PH.D., F.A.P.H.A.

*Third Vice-President and Statistician, Metropolitan Life Insurance Company,
New York, N. Y.*

ON previous occasions, I have pointed out that the tuberculosis problem in the United States is on the way to solution, and although war conditions may cause a setback, this may be expected to be only temporary. There are, however, a number of difficulties which must be overcome before our tuberculosis problem is finally resolved. For example, there is still a heavy concentration of the disease among Negroes, Mexicans, and Indians. Less serious, but nevertheless troublesome, is the high incidence of tuberculosis in certain occupations. Today, I wish to call your attention to a third situation, namely, tuberculosis among the veterans of our armed forces. In our campaign to eradicate the disease, this constitutes a hurdle whose magnitude and insidiousness have not been sufficiently appreciated. I am sure that health officers will wish to know the facts and will be eager to deal with this difficulty, as well as with the other two which I have mentioned. Their help is particularly needed in creating a new setup for the veterans, now that we are involved in the greatest war in our history, with larger numbers of our own men and women in the armed forces than ever before.

Let us review the development of the tuberculosis problem among veterans and what has been done to meet it. During the first World War, knowledge and facilities for the diagnosis of tuberculosis were inadequate to screen out at induction many of the men who were suffering from the disease, particularly in the early stages before symptoms appeared. This fact resulted in the later discovery of many active cases in the Army; the hardships incidental to the training program and to war duties produced still more. After the war, care of these tuberculous veterans was entrusted to the newly organized Veterans' Bureau. Many hospitals and sanatoria were erected for their treatment, and this service became a major medical activity of the bureau, and of its successor, the Veterans' Administration. As early as 1923, there were 23,653 veterans with tuberculosis admitted for treatment in hospitals or other agencies supported by the bureau. At first, such care was limited to those whose tuberculosis was connected with their military service; but subsequently more generous provision was made, so that those whose disease was unrelated to their military service (non-service-connected disability) also became eligible for treatment. As a result, the number of admissions for tuberculosis has continued large. As recently as the fiscal year 1942, after almost a quarter

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

century, the total hospital admissions for the year numbered 9,658. For the entire period since the last war, there have been over 300,000 admissions of tuberculous veterans to hospitals of the Veterans' Administration or to other government, state, or civil institutions. However, as we shall see later, these admissions do not correspond to that many different patients.

The government has been most generous in meeting its obligation to tuberculous veterans. There has been an extraordinary expansion in the physical facilities for treatment. No efforts or funds have been spared in erecting hospitals of the latest type with excellent equipment, and with as good medical personnel as could be obtained. In March, 1942, there were 5,217 beds in operation to meet current needs, including those of veterans of the present war. This figure includes beds for the tuberculous in veterans' psychiatric hospitals. The number of beds for these purposes has naturally declined, as tuberculous admissions have become fewer. In addition to having all the costs of their hospitalization and transportation to the hospital paid for by the government, tuberculous veterans also receive a disability payment. Those with service-connected disability resulting from active pulmonary tuberculosis receive from \$70 to \$100 per month, depending upon the degree of disability. Those with non-service-connected disability receive \$40 per month, if totally and permanently disabled. However, those without dependents receive a much smaller payment during hospitalization—\$20 in service-connected cases and \$8 in non-service-connected cases. For men who are treated at home, there is available an additional payment of \$50 per month to the wife or other person attending the patient. I should point out here that these financial arrangements have had the unfortunate effect of providing

an incentive to many men to discontinue hospital treatment and to attempt a cure at home.

The standards of operation in veterans' hospitals are of a high order, as is indicated by the ample sums set aside for cost of treatment. Thus, in 1942, excluding overhead costs, the per diem cost of operation for the tuberculosis hospitals of the Veterans' Administration was \$4.37 per patient. This has brought the total direct costs of treatment during 1942 to about \$8,000,000. Payments to veterans with either partial or total disability due to tuberculosis, whether or not service-connected, amounted to approximately \$40,000,000 during the fiscal year 1942. It is notable that the number of such cases for World War I still numbered 63,000 in 1942. The great majority of such persons are receiving pensions for permanent partial disability. The number receiving disability payments is many times that receiving treatment in hospitals. The amount paid in disability claims over the last twenty-five years is in the neighborhood of a billion dollars. In addition, there have been substantial payments to dependents of tuberculous veterans who have died.

In spite of the extraordinary development of the services for tuberculous veterans, the experience of the veterans' hospitals has been unfavorable. Thus, in 1942, of the 9,854 cases discharged from these hospitals, only 1.9 per cent were designated "arrested" at discharge; only 0.3 per cent "apparently arrested," and only 0.8 per cent "quiescent." If we combine these three categories, the fact emerges that only 3 per cent of the patients discharged during the year were medically rehabilitated. The remainder of the cases were discharged as "condition improved" 32.7 per cent; "condition unimproved" 28.9 per cent; "dead" 19.5 per cent; and "condition not

stated "16.0 per cent. It is clear that the vast majority of the patients discharged were not yet ready to be released to civilian life. The so-called "improved" cases represent, for the most part, patients with unstable lesions. As a matter of fact, a very large proportion of them left without authorization or consent. Thus, the Veterans' Administration itself classified the hospitalization of 58 per cent of the cases as "incomplete." The 1942 figures on condition at discharge from the Veterans' hospitals are rather typical, somewhat worse but not greatly different from those of earlier years. At no time since 1929, when the present type of report of the Veterans' Administration began, has the total for the "arrested," "apparently arrested," and "quiescent" reached 6 per cent.

Admittedly, one cannot make exact comparisons among various sanatoria as to results of treatment on the basis of crude figures of this type. This is particularly true now, for with the passage of the years, the usual case admitted to the veterans' hospitals is of the chronic type common among middle aged and older persons. Thus, of recent admissions, only 4 per cent were "incipient" cases, 22 per cent were "moderately advanced," and 74 per cent were "far advanced." With all due allowance for this fact, there is a painful contrast between these recent figures (as well as those of earlier years) and the results obtained in well managed state, municipal, and private sanatoria. Thus, in a country-wide survey of tuberculosis hospitals and sanatoria in the United States during 1933-1934, made by the American Medical Association, patients with tuberculosis "arrested," "apparently arrested," or "quiescent" on discharge, accounted for 29 per cent of the total discharged. A survey of discharges from the Michigan State sanatoria from 1930 to 1934 also showed a high proportion of

cases in these three categories—61 per cent of the total discharged. The experience of the Mount McGregor Sanatorium of the Metropolitan Life Insurance Company for males discharged between 1919 and 1936, and *excluding incipient cases*, showed that 48 per cent, or practically half of the cases, were "arrested," "apparently arrested," or "quiescent" on discharge; and even for the cases far advanced on admission, this proportion was 34 per cent.

There are clear reasons why this deplorable situation among tuberculous veterans has developed. The failure is not due to lack of desire to help these men. It was certainly the aim of everyone connected with the service to do as much as possible for them. The chief difficulty was lack of appreciation on the part of legislators and others interested in veteran welfare, of certain fundamental conditions necessary for the effective treatment of tuberculous patients. In part, outside pressure was brought to bear to liberalize financial provisions for these veterans. The effect of these measures has been to reduce control over the movement of tuberculous patients to a minimum. The veterans are not subject to the usual type of hospital restrictions, but may come and go almost at will, irrespective of their condition and against medical advice. There are cases on record where veterans with tuberculosis have left and then been readmitted as many as 24 different times. Six to 8 admissions of the same patient are a common occurrence in spite of much effort on the part of Administration officials to educate and persuade patients to stay in hospitals until completion of treatment, and in spite of certain measures to control offenders through exclusion from re-hospitalization for certain periods. The type of discipline that is so essential to success in the care and treatment of the tuberculous patient is lacking, for the most

part, in veterans' hospitals. Indeed, the laws and practices relating to these veterans have so developed that it is often financially advantageous for the patient to leave or to stay away from the hospital altogether. This, of course, is an impossible situation. It has served to undermine the morale both of the tuberculous veterans themselves and of the doctors and other members of the professional staffs serving them.

But the situation in the veterans' hospitals has had results which most health officers will consider more serious even than failure to rehabilitate men already suffering from the disease. The discharge of men before they are cured has left its toll on the entire country. It has allowed thousands of veterans with active tuberculosis to return to civilian communities each year. It has made it possible for fairly large numbers of open cases to live at home, under little or no medical supervision. These men have traditionally been looked upon as wards of the federal government and consequently the state and local health officers have taken little responsibility for them. Actually, however, the control of the Veterans' Administration over these men has been rather loose. Few of the patients have gotten well; the great majority have constituted an army of discouraged men who have become centers of infection for new cases of tuberculosis in the communities to which they have returned after treatment in the veterans' hospitals.

The authorities in the Veterans' Administration, as well as leaders in veterans' affairs, have become aroused to the need of correcting this whole situation. It will not be any easy task because it involves a rather complete change in viewpoint, and it touches what may be called a "vested interest" in certain benefits. Consideration is now being given to specific

methods of improving matters, and, in due course, the necessary legislative measures will come up for consideration. In an effort to get tuberculous veterans to resume sanatorium treatment and stay until satisfactory results are obtained, the American Legion is launching a campaign to have each local branch do the necessary missionary work among members in its own locality and to see that the veterans continue hospital treatment until discharge by the doctor.

As health officers, you can help in many ways. First of all, you can bring pressure to bear for revision of the generous but ill-advised legislation that has been in part responsible for present conditions. The current laws are altogether too loose in their benefits to veterans. There must be new controls to make these benefits not only liberal but medically effective. Legislation must discourage the uncontrolled movement of tuberculous veterans until the disease is "arrested" or at least until it is not a community menace, just as the movement of psychiatric veterans is supervised and curtailed.

Second, you can cooperate with the Veterans' Administration in the follow-up of tuberculous patients who have left veterans' hospitals. The Veterans' Administration has indicated that it will release such information to state and local health officers, and routine procedures for getting such reports should be set up without delay. It will be the responsibility of your departments to make available locally the necessary social and medical services for those tuberculous veterans who are unwilling to use the federal facilities. If these men are still in need of sanatorium care, they should be hospitalized either in state or local sanatoria. Whenever it seems necessary to invoke your legal power to enforce compulsory hospitalization or isolation, you must do so.

Apart from this, I would suggest that each of you investigate independently the facts with reference to tuberculous veterans in your own state or community. A canvass and follow-up of the list of those who are reported to have tuberculosis would probably show many such cases in your jurisdictions. As I have indicated, most of them are middle aged men, many of them centers of infection and chronic offenders against all reasonable hygienic precautions. Because of their status as veterans and their habituation to the loose hospital discipline which I have mentioned, they feel privileged to do pretty much as they please. These men should be sought out and cared for, and, if necessary, isolated for the protection of their families and their neighbors. I am convinced that this situation in your local communities constitutes one of the most serious difficulties in the national effort to eradicate tuberculosis.

Frankly, I do not know how much we shall be able to accomplish with the old veterans. But I feel that a genuine and earnest effort must be made to protect the new and large crop of tuberculous veterans who will inevitably emerge from the present war. As early as the beginning of July, 1942, their number had already exceeded 800. By this time, the war's tuberculosis victims are probably counted in thousands. From present indications, there is danger that the Veterans' Administration may be compelled to function under the same regulations and procedures which govern the care of veterans of World War I. There is already evidence that all is not well with the new tuberculosis victims, and that they are showing the same restlessness, the same abandonment of regular hospital care, which has produced such calamitous results among the older men. The stage may be set for another great medical tragedy; and unless we take action, I believe that

lack of discipline and mistaken generosity may not only take their toll of these young men—who should by all reason get well and be sent back to their communities to take up a useful life again—but may also seriously delay our control of tuberculosis in the general population of the country.

But we can avoid such a situation. I am calling these difficulties to your attention because they can be met and rectified right now, if we all work together toward a sensible program at the start. The present situation is far more favorable than it was during the last war. We have at our disposal excellent medical facilities and improved skills in treatment. The new crop of tuberculous veterans is more apt to be in the early stage of the disease, when cure or arrest is most rapid and sure. The Veterans' Administration and the American Legion are both aware of the seriousness of the situation and are eager to coöperate with the state and local health officer in any plan to help veterans to be cured and to protect the families of the men from infection. Working toward the same objectives, you health officers, together with these two organizations and with a public and government both increasingly aware of their responsibilities toward the veterans of this war, should be able to bring about really constructive action. Through such an outlook and such teamwork, the young tuberculous veterans should benefit by every medical facility and enlightened service we can offer. There is every reason why a large proportion of them should return to their homes as productive citizens, rehabilitated medically and industrially. As health officers, you have an extraordinary opportunity to contribute to this program, and to shape the future of these veterans, as well as of the tuberculosis movement all over the country.

Public Health Degrees and Certificates Granted in the United States and Canada During the Academic Year 1942-1943*

THE Committee on Professional Education of the American Public Health Association presents a report of public health degrees and certificates granted in the academic year 1942-1943. With the exception of public health nursing tables, the committee has included only graduate students enrolled in courses leading to graduate degrees and certificates. The basis for the record is *the number of students who received degrees* rather than the number of degrees granted in the specified period.

Graduate Students Enrolled and Degrees Granted in Public Health Engineering and Sanitary Engineering Courses in the Academic Year 1942-1943

In the academic year 1941-1942, 163 graduate students were enrolled in public health engineering and sanitary engineering courses as compared with 64 in the academic year 1942-1943. Graduate degrees and certificates granted in the academic year 1941-1942 totaled 89 as compared with 24 in the year 1942-1943.

Air Disinfection in Day Schools*

W. F. WELLS

Associate Professor in Research in Air-borne Infection, Laboratories for the Study of Air-borne Infection,[†] Department of Preventive Medicine and Public Health, University of Pennsylvania School of Medicine, Philadelphia, Pa.

THE prevalence of respiratory infection during the season of indoor congregation¹ suggests a natural relationship between ventilation and communicable disease. Reduction by radiant air disinfection, of surgical infection² and cross-infection between sick children continuously exposed in pediatric wards,³ and continuous aggregations of infants in a nursery⁴ and children in an orphanage⁵ and dynamic spread of childhood contagion⁶ through intermittent aggregations in classrooms of day schools⁷ offers experimental evidence of the importance of sanitary ventilation in the control of respiratory disease. It may not now be premature in the interest of good design, to attempt a preliminary comparison of results from 6 years' study in one irradiated school with the results obtained under a different design during 3 years in two other schools.

GERMANTOWN FRIENDS SCHOOL

The educational standards which attracted pupils from a select class in a large urban population to the Germantown Friends School contributed much to the significance of the data. The social stability of this class insured

unusual continuity of the pupil population from entering susceptibility to graduating immunity, giving cumulative significance to epidemiologic school experience. The dispersal of the pupils through a narrow social stratum of a wide population minimized simultaneous exposure to local epidemics outside the school which might confuse the school pattern. Intelligent coöperation of the staff and parents guaranteed the reliability of the intimate records essential to intensive analysis of the spread of contagion, and health records available for the previous 5 years provided a helpful background.

School arrangements were also well fitted to the needs of the study. Except for a corridor connecting the third floors of the two buildings, the four susceptible primary grades were separated from the four intermediate and four senior grades. Each grade was divided into two classes of approximately 20 pupils in similar classrooms of about 6,000 cu. ft. capacity, ventilated by windows. Irradiation of the upper region of each "home" room above the 7 ft. level, by two crossed, "Safe-t-aire" quartz tubes in a shallow aluminum pan reflector, especially designed for the purpose by the Hanovia Chemical and Manufacturing Company, provided uniform air disinfection. Central fixtures were also hung in the nature and music rooms and in the library, but corridors, lunchroom, gymnasium, shop and restroom were equipped according to special

* Presented in part before the Engineering Section of the American Public Health Association at the Seventy-first Annual Meeting at St. Louis, Mo., October 30, 1942.

[†] Supported by a grant from the Commonwealth Fund to the University of Pennsylvania for the study of the mechanics of air-borne infection and control.

needs. Correlation of sanitary and epidemiological indices of disinfection of standard "home" rooms then became the specific objective of the study.

SANITARY INDICES

Irradiation—The lethal rating of a tube was given as 1,000 milliwatts of 2,537 Å radiation. In a uniform parallel beam (as from the sun) radiation from two tubes could theoretically irradiate a cube of the same volume as a room to an intensity of 6.06 mw. per sq. ft.⁸ Since not more than half the radiation in all directions can be realized from artificial sources in a room with nonreflecting walls, the theoretical irradiation from half the lethal rating is arbitrarily adopted as 100 per cent efficiency.⁹ Irradiation efficiency is then derived from average intensity * (1.25 mw. per sq. ft.), yielding 42 per cent efficiency of irradiation.

Air Disinfection—It is possible by defining the lethal equivalent of an air change to express air disinfection in ventilation terms. The lethal rates of most pathogenic air-borne bacteria when exposed to ultra-violet radiation are similar enough to define the disinfection unit equivalent to one air change as the exposure required to reduce *Escherichia coli* atomized into dry air by 63.5 per cent—called a *lethe*. Thus it has been found that as uniformity of exposure is approached, a milliwatt foot of 2,537 Å radiation⁹ will approach the sanitary equivalent of a cubic foot per minute of air displacement, and we may assume for practical purposes this arbitrary definition of a *foot lethe* as the unit of radiant disinfection of air. Efficiency of disinfection, however, falls with variable exposure to different intensities indicated by low irradiation efficiency, but air circulation tends to equalize

exposure of air-borne organisms to variable intensities. The foot lethal equivalent of an air change per minute determined by bacteriological methods¹⁰ at the Germantown Friends School, divided by the computed milliwatt feet, gave 63 per cent disinfection efficiency. This effective utilization of irradiation certifies to the propriety of correlating this sanitary index with epidemiologic indices.

EPIDEMIOLOGIC INDICES

Secondary Class Incidence—An epidemiologic index of sanitary ventilation requires estimation of exposure, incidence, and susceptibility. Where outside exposure is eliminated by continuity of aggregation, and other modes of spread can be controlled, total incidence of respiratory disease may indicate air-borne infection. Uncertainty of diagnosis, multiplicity of exposure, and doubtful immunity, vitiate indices based upon colds among intermittent aggregations.⁷ Childhood contagions, largely confined to a narrow age stratum, and therefore less subject to simultaneous class incidence from extramural exposure, provides the best index of air-borne infection in schools.⁷ If we assume cases of measles, mumps, and chicken pox to be classroom infections when they appear within a proper incubation period after classroom exposure to pupils in an infective stage, the error will be small compared to difference needed to make contagious disease data significant. Though less determinate, this procedure is basically analogous to determining secondary attack rates in families.

Patterns—The occurrence of epidemic respiratory contagion among school children need not reflect upon the efficiency of sanitary barriers unless sanitary ventilation is generally practised in the community. Successful control of spread of contagion within the school will, on the other hand, alter

* Milliwatt feet divided by room volume in cubic feet.

⁹ Milliwatt feet = the summed products of angular flux density and radiant distance in feet⁹

epidemic rates and proportionate incidence, and ultimately modify immunity patterns in a school population. Thus increased susceptibility of grades following irradiation of the primary school, together with lower rate of spread and proportion of class secondaries may provide a more reliable index of sanitary control than comparisons of incidence between small "controlled" groups, for exposure cannot be "controlled." Conversely, successful control will indicate the importance of an aggregation among community channels of contagion spread.

Results—During the first year (1937-1938), 89 children in four primary classes constituted a protected group, and the same number of similarly susceptible children in four corresponding classes constituted a control group. Seven introductions of mumps into each group resulted in 12 secondary cases in the control group and only 2 in the protected group.

The whole primary department was irradiated during the next session, when another epidemic of mumps, commencing on October 3, spread dynamically (27 cases) through the intermediate department (65 per cent susceptible), but flickered out in both the primary and senior departments. Failure of epidemic spread in the senior department might be explained by lower susceptibility (56 per cent), but more probably by irradiation of the more susceptible (74 per cent) primary department.

Chicken pox introduced 21 times into the primary department (average susceptibility 59.8 per cent) between December and the closing of schools (1939-1940), resulted in only 7 possibly secondary infections. An explosive outbreak in a particular class singled out to rehearse a school play in an unirradiated auditorium, however, exhibited a typical air-borne pattern. On 4 successive days this class was exposed

to a missed case (sole secondary to a previous class exposure under the lights), diagnosed the evening before the play, and between the 14th and 20th day following the first day of exposure (May 8), 15 out of the 16 reportedly susceptible children came down in a static type of epidemic characterising intense common-source exposure.

SWARTHMORE STUDIES

The results of the first 3 years at the Germantown Friends School encouraged the extension of the demonstration to the small socially isolated college community of Swarthmore. The educational ideals of this community attracted an intellectually selected class of residents from Philadelphia, insuring in a public school system the epidemiologic advantages enjoyed in the private school at Germantown and similar epidemiologic opportunities to study the part the school played in community spread of a contagion. School cases embracing the whole childhood population became identical with community cases; so differentiation of outside and school exposure distinguished the part the school played in the community commerce in contagion.

The primary grades (kindergarten through the 6th grade) are accommodated in two schools, both merging into one high school of the 6 upper grades. The College Avenue Primary School is located on the same grounds as the High School, but the Rutgers Avenue School is about a mile away. This exposure of one-half of the primary population to upper grades constitutes an interesting variation between two otherwise equivalent epidemiologic and sanitary situations.

The modern school buildings were designed according to standard (Pennsylvania) specifications as to space, light, and ventilation. Mechanically ventilated classrooms of about 7,000 to 8,000 cu. ft. capacity, each accommo-

dating some 20 to 30 pupils, were equipped with four 30 watt fluorescent type of "Germicidal" tubes in high transmission glass, provided with fixtures by the General Electric Company. Corridors, lunchroom, gymnasium, and other places where children mingle, were not irradiated—an epidemiologic opportunity but a sanitary error.

Sanitary Indices—Two reflectors were installed on each end wall at 7 ft. levels, and not being specially designed for the purpose, directed the light beam upward at an angle of 60° from horizontal to avoid direct irradiation of the occupied zone. Only the remote angles between the end wall and ceiling were heavily irradiated, and ray lengths were limited to the distance between the light and the ceiling. Though the rated lethal radiation from the four tubes was tenfold that in the rooms at Germantown, the average irradiation in milliwatt feet per cubic foot (7.64) was only five times greater. The lower efficiency of irradiation (28 per cent as against 42 per cent) indicates a poorer distribution of irradiation, and a correspondingly low efficiency of disinfection (26 per cent as compared to 63 per cent at Germantown) yielded only two equivalent air changes per minute. The steep concentration gradients shown by tests made at different points in the room also indicated non-uniform exposure of the organisms.

MEASLES ⁷

During the 8 months, October, 1940, to May, 1941, more than 25,000 cases of measles were reported in Philadelphia—the largest number on record. Though the total cases in the Germantown Friends School and also in the Swarthmore schools exceeded the number in any one of the previous 10 years, this was not due to cases in the protected primary classes, but in the upper unirradiated grades where more than twice the total of the previous 9 years

occurred. Only 32 per cent of the school cases occurred in the irradiated classes, while 77 per cent occurred in these grades prior to irradiation. Since exposure outside the classrooms varies inversely with the proportion of school secondaries, the difference in irradiated and unirradiated rooms is even greater than these percentages indicate.

In the town of Swarthmore, hardly more than one-third (37.5 per cent) of the cases occurred at primary school ages, and nearly one-half (46.1 per cent) at high school age, but in Philadelphia as a whole, as in previous years, two-thirds of the cases occurred in primary school ages. In the district adjoining Swarthmore, the attack rate in three primary Nether Providence Schools was four times that in the corresponding high school, and in the grades corresponding to the irradiated grades of the Germantown Friends School, at the nearby William Penn Charter School, there were five times as many cases as in the upper grades.

Weekly attack rates among susceptibles in upper unirradiated classrooms were five times higher than in the irradiated primary classrooms. In the two primary schools sharing grounds with the upper schools, the attack rate was double that in the isolated Rutgers Avenue School at Swarthmore, though home secondaries showed no significant difference, and the small proportion of class secondaries also implicated upper school exposure rather than epidemic spread within their own classrooms. The curve of proportionate decline in the percentage of susceptible children in irradiated and unirradiated rooms during the course of this epidemic (Chart I) shows higher percentage susceptibility in the protected classes after the epidemic had passed than in the control classes before it commenced. The inflection point of this curve coming 13 days (incubation period of measles) after that for the unirradiated classes, like-

MEASLES

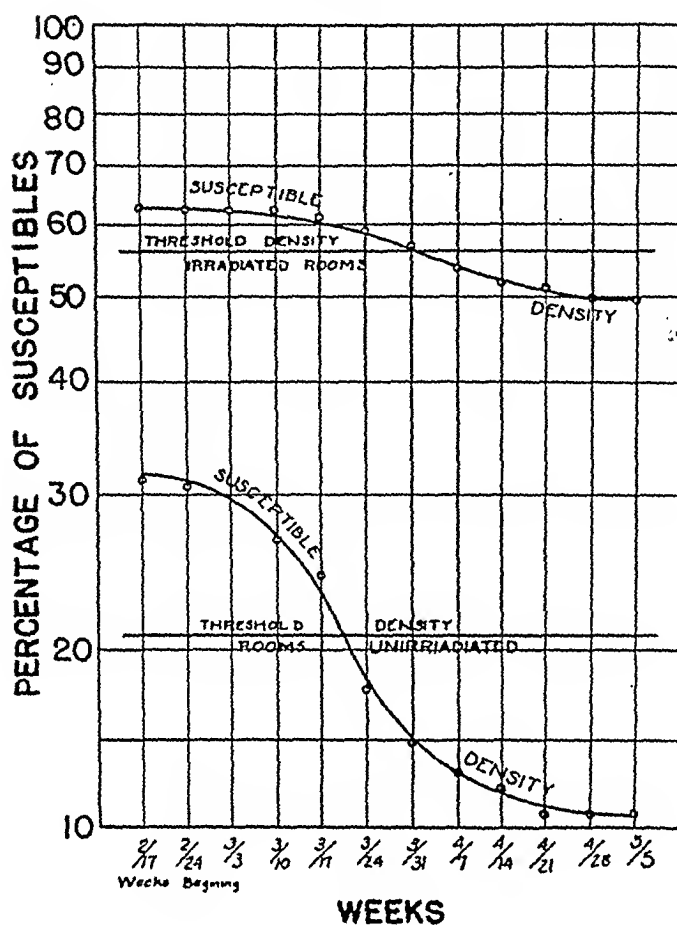

CHART I—Measles susceptibility in Germantown Friends School and Swarthmore Public Schools during 1941 epidemic (primary classrooms irradiated). Threshold density of susceptibles indicated at point of inflection in accordance with McKendrick's theory.

wise indicates secondary spread from the unirradiated school rather than dynamic spread within the primary irradiated classrooms.

The swift course of the epidemic through the schools swept out susceptibility before secondary spread in the community could become established, and so accounts for the similarity in pattern at the Germantown Friends School and in Swarthmore. Occasional class secondaries in some of the irradiated Swarthmore classrooms were overlooked, since the lights were not operated from a central switch as at Germantown, but responsibility rested

on each teacher for her room, and more than once the principal was called out after sundown to attend to a "peculiar violet light" in his school.

MUMPS⁶

The dynamic pattern of spread of mumps through the community of Swarthmore during the succeeding year accentuated epidemiologic and sanitary complications in an experimental study of air-borne infection among human aggregations. A case of mumps, exposing the 3rd grade of the College Avenue School on September 29 and 30, detonated an explosive accumulation of

susceptible material. On the second and third generations, synchronous epidemic waves were initiated in the 1st and 2nd grades, respectively. Waves of decreasing amplitude then fanned out on an ever-widening front through the entire population of Swarthmore during the remainder of the season.

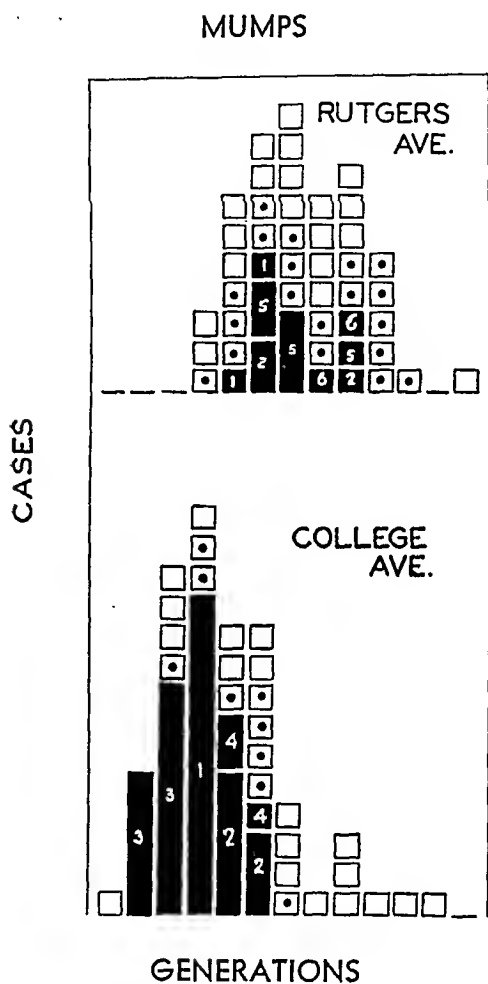

CHART II—Mumps in Swarthmore Primary Schools, 1941-1942. Cases plotted against generation periods. First introduction September 30. Each bar represents one generation period beginning October 7, 25, November 10, 27, December 14, January 1, 19, February 6, 24, March 14, April 1, 19, May 9. Black bars indicate class secondaries defined by cases occurring from 13th to 22nd day after class exposure on day of onset or previous day. White numbers on black bar represent the grade. White squares represent extra class infections. Black dots indicate home secondaries.

The localization of epidemic classroom spread (indicated in black on Chart II), to classes exposed during the fall, contrasts with the generalized endemic smouldering through the community after classroom spread ceased with the onset of cold weather. Thus the secondary class incidence at the College Avenue School, exposed earlier in the season, was more than double that in the more susceptible and more heavily exposed Rutgers Avenue School. In three primary classes first attacked, 32 out of 42 cases could have been secondary to 23 classroom exposures, but only 15 of 73 cases in 11 remaining primary grades of comparable susceptibility could have been secondary to 30 class exposures. Similarly, 31 of 51 cases in the two primary schools could have been infected by 18 class exposures between September 30 and November 19, yet 53 class exposures between November 18 and April 7 could account for no more than 16 of the 64 cases infected after November 18, and probably some of these were extra-class infections. Some factor favorable to epidemic spread of mumps during mild, moist, fall weather appeared to be under control during the cold winter weather.

Epidemic spread of mumps through these irradiated classrooms in the fall, if air-borne, presents a sanitary complication. Direct experimental evidence that mumps virus can be spread through the air, or destroyed by ultra-violet lights, is indeed lacking, and the epidemic behavior of mumps is notoriously erratic. But epidemiologic evidence indicates that "the infective agent of mumps is transmitted by the air"¹¹ epidemically as well as endemically by salivary communism,¹² and epidemic spread in irradiated classrooms seemed in previous winters to be controlled, and ceased this year with onset of cold weather. An air-borne pattern between the season of abundant window ventilation and the season of dry indoor air

could be explained if the viricidal efficiency of the irradiation is decreased at high humidity.¹³ Between September 30 and November 19, weather reports indicate that on 16 days indoor relative humidity exceeded 70 per cent; on 19 days 60 per cent, and 27 days 50 per cent, accountable for a loss of more than half of the bactericidal efficiency in dry indoor air during cold weather. The problem, however, is too serious to be dismissed without further exhaustive laboratory and field investigation.

During the winter, the school now plays a more important rôle in spreading contagion among high school ages than among the primary school children in the town of Swarthmore, and the College Avenue School similarly plays a more important rôle in the spread of contagion among primary school children than the Rutgers Avenue School. Except for minor episodes unattributable to design, but which do emphasize the importance of vigilant servicing, the last year has been uneventful.

DESIGN

A truly quantitative specific secondary attack rate would require correction for time and intensity of exposure, multiple infections, and susceptibles exposed. Under epidemic conditions where rapidly increasing exposure corresponds with a large decrease in susceptibility, the correction would be greater than under sporadic conditions of spread. In fact, the necessary condition of epidemic spread, a higher specific secondary incidence than specific exposure, would normally be unobserved, for indicated secondary incidence ordinarily approaches indicated exposure. Actual differences in rate of spread would therefore exceed differences in the indicated ratio of secondary incidence to exposure.

During the period of dry indoor air, about one in every four exposures of

irradiated classrooms to measles, mumps or chicken pox was followed by one or more secondary cases, both at the Germantown Friends School and in the Swarthmore primary schools. A third more cases per outbreak at the latter indicates that failures, though no more frequent, were more serious—epidemiologic confirmation of the sanitary indices of disinfection efficiencies. In neither case does the ratio of secondary incidence to exposure correspond with an epidemic condition of spread indicated by the nearly equal number of secondary cases and exposures in the unirradiated intermediate department of the Germantown Friends School and unirradiated primary schools. In the absence of records of classroom exposure prior to irradiation, it is still possible to estimate crude presumptive primary and secondary incidence by assuming that all cases exposed their classes. The number of presumptive "secondary" cases indicated under this assumption has been reduced to less than one-third by irradiation of classrooms, though the number of presumptive "primary" cases has not been markedly changed.

It may seem somewhat contradictory that rooms with double the disinfection, five times the irradiation, and ten times the radiation should prove to be hygienically less efficient, though this is consistent with the lower sanitary indices of disinfection and irradiation efficiencies. It indicates that respiratory organisms travel less frequently from person to person through lethal zones. Bacteriological tests showed that rotation of the reflectors to throw a horizontal beam across the room increased irradiation more than threefold and disinfection more than tenfold. That an even greater hygienic efficiency can be expected has been indicated by the superior epidemiologic indices within rooms with one-half the disinfection and one-fifth the irradiation but with higher disinfection and irradiation efficiencies.

SUMMARY AND CONCLUSION

1. Epidemic spread of childhood contagion in irradiated classrooms during winter months appears to have been checked for 6 years at the Germantown Friends School and for 3 years in two primary schools at Swarthmore. Measles, mumps, and chicken pox prevailed during the same period in unirradiated classrooms in these schools and in nearby primary schools.

2. Epidemic spread of mumps in irradiated classrooms (of one of these schools) exposed during the fall was checked with the onset of cold weather.

3. Failure of the lights to control the epidemic spread of mumps during the moist, mild autumn weather suggests that the viricidal activity of ultra-violet light decreases with humidity. When respiratory infection is normally most prevalent during cold weather and indoor air is dryest, irradiation was efficient.

4. The importance of the classroom in the epidemic spread of childhood contagion through the community of Swarthmore was revealed by radiant disinfection of the air of the primary schools.

5. The design which yields the highest average intensity per unit of ultra-violet light radiated into a room (i.e., highest efficiency of irradiation) will generally accomplish the most disinfection per unit of intensity (i.e., highest efficiency of disinfection), and prove hygienically more effective per unit of disinfection (i.e., highest hygienic efficiency). An installation with several times the radiation per cu. ft. performed less consistently, according to epidemiologic indices, than one with higher

efficiencies of irradiation and disinfection.

ACKNOWLEDGMENT—Though many to whom I am indebted for the data utilized in this discussion have been recognized in the references, I am especially indebted to Dr. Mildred W. Wells and Dr. Theodore S. Wilder for the privilege of examining the full epidemiologic data soon to be reported, which undoubtedly influenced the opinions here expressed.

Some Medical Aspects of Protein Foods*

FREDRICK J. STARE, M.D., AND GEORGE W. THORN, M.D.

Schools of Public Health and Medicine, Harvard University; Medical Service, Peter Bent Brigham Hospital, Boston, Mass.

SINCE protein in adequate quantity and quality is necessary for all forms of life, its relation to problems of health and disease are without limit. But to be more specific and practical one may mention some of the problems of medical interest where there is experimental evidence for the importance of protein. Some of these are listed in Table 1.

TABLE 1

Problems of Medical Interest Related to Protein Foods

Physiologic:

Growth	Immunity and Resistance
Pregnancy	Absorption of Other Nutrients
Lactation	Appetite
Bone Formation	Hunger
Blood Formation	Fatigue

Pathologic:

Convalescence	Edema
Wound Healing	Obesity
Diseases of Liver	Wasting Diseases
Diseases of Kidney	Impaired Gastrointestinal Absorption

It may be well to recall at this time the difference between the terms protein foods and protein. Protein foods are sources of protein, but they are also excellent sources of other important nutrients—minerals, vitamins of the B-complex, and frequently fat and fat soluble vitamins. In practical human nutrition, in nutritional studies on human subjects, and in clinical therapeutics, it is usually impossible to separate effectively these various nu-

trients furnished by protein foods. Hence it is difficult to interpret the results precisely. Thus a high protein diet usually results in an increase of other important nutrients and a low protein diet may be deficient in nutrients other than protein. It is obvious and imperative that if any significant decrease in the protein supply of an individual or of a nation is considered, an accurate evaluation of nutrients other than protein, but generally furnished by protein foods, be made.

How much protein does a healthy adult require? How much of this protein requirement must be supplied by animal protein as compared with vegetable protein? Does exercise increase the protein requirement? These are old questions that have brought forth warm discussion ever since the days of Rubner and Voit—and questions which are still under discussion. Today the protein nutrition of mammals is recognized as nutrition by essential amino acids, and research of the last two years has shown that man fits well into this concept. Thus Holt and coworkers at Johns Hopkins have shown that tryptophane, lysine, and methionine are required for the maintenance of nitrogen equilibrium in man and that arginine is essential for normal spermatogenesis. Rose at Illinois has recently maintained nitrogen equilibrium in young adults on a mixture of eight amino acids. Whipple at Rochester has found that a mixture of

* Presented by invitation before the Division of Agricultural and Food Chemistry, American Chemical Society, Pittsburgh, Pa., September 10, 1943.

pure amino acids is as effective in restoring plasma protein, and presumably therefore body protein, as such proteins as casein and beef serum. The answer to how much protein one requires is simply that amount of protein which provides an adequate quantity of essential amino acids. It makes little difference whether they are furnished by animal or vegetable protein. Data available at present, however, are too fragmentary to provide accurate information concerning either the amino acid composition of various protein foods or the quantity of essential amino acids required by man.

From the practical viewpoint, the protein requirement of man is definitely related to the amount of carbohydrate and fat in the diet. If there is sufficient energy yielding food available so that protein will not be used appreciably as a source of energy, then the protein requirement will be considerably less than if a significant amount of the protein is required for calories.

We should like to mention briefly a recent investigation* which gives considerable practical information on the questions of protein requirement, how much of this should be animal protein, and the effect of exercise on the protein requirement.

This was a study of dietary protein in relation to physical efficiency which was planned and conducted by R. E. Johnson, R. C. Darling, and W. H. Forbes of the Harvard Fatigue Laboratory with the coöperation of the Division of Nutrition of the Medical and Public Health Schools of Harvard University. The subjects were 24 volunteers from Civilian Public Service Camp 32, West Campton, N. H. They were all

physically normal young men who continued their usual activities about the camp throughout the course of the experiments. The range of daily caloric expenditure, depending on the subject's job, was 2,400 to 5,000. Every attempt was made to interfere as little as possible with the normal daily routine of the subjects.

The men were divided into 3 groups of 8 men each. The normal control group subsisted on the camp diet, which by the standards of the Food and Nutrition Board of the National Research Council was good, and provided an average of 100 gm. of protein a day. The low protein group subsisted on a diet from which all meat, eggs, fish, nuts, legumes, cheese, and almost all milk were excluded. Their diet consisted essentially of cereal products, potatoes, other vegetables, fruit products, and oleomargarine, with not over 4 oz. of milk and cream a day. The high protein group was encouraged to replace low protein foods with foods rich in protein, such as meat, milk, cheese, eggs, nut products, especially peanut butter, and legumes. Following a 2 week period of observation when all of the subjects were on a normal diet, the experimental regime was followed for 2 months. Then for 2 weeks, the normal group continued on a normal diet, the high protein group reverted to normal, and the low protein group turned to high protein. No attempt was made to limit total caloric intake.

On each of the subjects the following observations were made: (1) a thorough medical examination during the normal period and at the end of the experimental period, (2) periodic estimation of red blood cells, white blood cells, hemoglobin, and differential count, (3) routine clinical examination of the urine, (4) medical interview once a week to ascertain if the subject was suffering from any complaint attributable to the

* The investigation referred to in this part of this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Harvard Fatigue Laboratory. The work will be reported in detail in a forthcoming paper by R. E. Johnson, *et al.*

diet, (5) weekly assessment of general physical fitness for hard work by the "pack test," which is a standardized exercise tolerance test designed by the Harvard Fatigue Laboratory, (6) weekly estimation of serum non-protein nitrogen, albumin, and globulin, (7) weekly estimation of nitrogen in a 24 hour specimen of urine, (8) meal by meal record of dietary intake (all food was either weighed or dispensed in standard portions and diet calculations were made daily. Standard food tables were used and the results obtained were frequently checked by direct analysis of food samples.), (9) a daily caloric expenditure in work was estimated from a continuous hour by hour diary kept by each subject.

The average daily protein intake of the low protein group was about 50 gm., of which not more than 5 gm. was in the form of animal protein. The 4 to 5 gm. of animal protein was furnished by occasionally on breakfast cereals. The normal group averaged 100 gm. of protein intake, of which about 60 gm. was animal protein. The high protein group had an average daily protein intake of about 160 gm., mostly animal protein. No members of the low protein group, not even the hardest worker, who averaged about 5,500 calories expenditure on a working day, suffered measurable deterioration in physical vigor. The only symptom that could be attributed to the low protein diet was voiced by the two hardest workers, one a farmer and the other a man engaged in hard work in the woods. These men usually felt quite hungry about 11:00 a.m. and 4:00 p.m. Nevertheless, their day's work did not suffer from the low protein diet. No significant changes were found in serum albumin or globulin of the low protein group. In view of Chittenden's finding that a low protein diet is in fact beneficial to physical vigor and efficiency, it may be

mentioned that the physical fitness of the subjects on the low protein diet was no better than that of the control or high protein groups. In the high protein group no measurable benefit to physical fitness from this large amount of protein could be observed in 2 months. No significant change was found in the serum albumin or globulin.

Thus, throughout a period of 2 months no measurable influence, either deleterious or beneficial, was seen in the physical vigor or efficiency in daily work of healthy young men subsisting on a diet providing 50 gm. of protein, of which not more than 5 gm. was animal protein. Likewise no beneficial or deleterious effect was observed in 2 months from a diet providing 160 gm. of protein, most of which was animal protein. One should emphasize that both of these diets were adequate with respect to calories and that a yeast concentrate was provided daily to the low protein group to insure an excess of vitamins of the B-complex.

It seems reasonable to conclude from this experiment that a daily protein intake of 50 gm., of which as little as 5 gm. consists of animal protein, is perfectly adequate for good health and efficiency providing, and this is a most important proviso, the diet is adequate in other respects, particularly calories and thiamine. In addition, confirmatory evidence is offered that exercise or hard manual labor does not increase the protein requirement. One might ask: why a diet of less than 50 gm. was not used in the low protein group. The reason is that it is practically impossible to plan a reasonably palatable diet of ordinary foods which will supply 3,000 to 5,000 calories and yet not contain that amount of protein.

This experiment should not be interpreted as implying that protein requirements of the normal adult can safely be reduced to 50 gm. per day, of which only 10 per cent need be ani-

mal protein—not unless the diet is adequate in other respects. In dealing with the health of the public it is no doubt safer to rely on a protein level of at least 70 gm. per day for the average adult man and 60 gm. per day for the average adult woman as recommended by the Food and Nutrition Board.

Interesting data on dietary protein and signs of protein deficiency have recently been reported by Youmans.¹ Out of a group of approximately 1,100 individuals in Tennessee that were studied in considerable detail, there were some 40 per cent who had a dietary protein intake of less than 50 gm. daily. In these 450 individuals who had been receiving less than 50 gm. of protein per day, probably for most of their lives, only 5 subjects, or 0.9 per cent, had clinical evidence of protein deficiency. Furthermore, the caloric intake of these subjects was in general low, and it is entirely possible that with an adequate caloric intake no signs of protein deficiency would have occurred.

A nutrition problem of industrial importance, and one which is of medical interest, is the fatigue and weakness that is occasionally experienced about 3 hours after eating a meal high in carbohydrate. Efficiency experts have long recognized the desirability of supplying intermediate supplementary nourishment to maintain the performance of office and factory personnel throughout the working day. In clinical medicine it is well known that a pronounced fall in blood sugar, usually accompanied by excessive fatigue and weakness, frequently follows the ingestion of large amounts of relatively pure carbohydrate. Thus ingestion of a typical American breakfast—one relatively high in carbohydrate and low in protein and fat content—predisposes to mid-morning hypoglycemia with its consequent weakness

and fatigue. Interesting experimental confirmation of this view has been obtained² by comparing isocaloric meals of varying composition. It was found that the ingestion of a breakfast high in carbohydrate was followed by symptoms of weakness, hunger, and fatigue in approximately 3 hours. An isocaloric breakfast high in fat was followed by similar symptoms but of lesser degree and after a longer time. An isocaloric breakfast high in protein was followed by an improved sense of well-being and no symptoms of hypoglycemia. The blood sugar levels following these three breakfasts corresponded closely to the clinical symptoms.

What are the effects of various diseases on the protein requirement? Are there diseases which result in a decreased protein requirement or in which a protein requirement below the recommended 1 gm. per kg. of body weight is desirable from the viewpoint of therapy? There are no diseases known which result in a decreased protein requirement.

In diseases which result in a marked increase in the non-protein nitrogen of the blood, such as certain phases of renal insufficiency, a low protein diet is desirable. However, nothing is gained by reducing protein intake below protein requirement, even in a patient with increased nitrogen in the blood, since any deficit in dietary protein will be made up by using body protein. Hence nitrogen end products to be excreted are not reduced, and in addition the body has suffered loss of tissue protein. In essential hypertension, or in renal disease in which the blood non-protein nitrogen is not markedly elevated, a diet of normal protein content, that is 1 gm. of protein per kg. of body weight is not contraindicated.

What of high protein diets? Are they harmful to the normal individual? Are they frequently desirable in clinical medicine? They most certainly are not harmful to the normal indi-

vidual and they are quite desirable in many clinical conditions. It is possible here to mention only some of the more obvious examples. The Eskimo is noted for robust health, and the diet of the Eskimo is very high in protein and fat.³ Explorers to the arctic and antarctic regions have occasionally existed for long periods of time on diets consisting almost entirely of protein and fat. This recalls the well known case of Stefansson who after many years of arctic exploration, during which time he lived on a high protein intake, lived in this country for one year on a diet consisting entirely of protein foods and fat. Prior to food rationing in this country it was common for many people to have a protein intake averaging 150 gm. per day, and to experience no harmful effects from such a high protein intake—in fact, such individuals are usually vigorous and robust.

In diseases characterized by loss of protein, such as nephrosis and the early stages of nephritis, or in cases of hypoproteinemia, naturally a high protein diet is very desirable. High protein diets are also of definite value in muscle wasting diseases. In fact, because protein foods carry with them abundant amounts of essential nutrients in addition to protein, their use in generous amounts in most diseases, particularly in convalescence, is to be recommended.

Recent investigations have indicated that dietary protein favors the absorption of calcium, of riboflavin, and of niacin. Lehmann and Pollak⁴ found that the carbonates and phosphates of calcium were considerably more soluble in solutions of amino acids than in pure water. McCance, Widdowson, and Lehmann⁵ using human subjects studied the effect of low and high protein diets, controlled experimentally by equal caloric rations of carbohydrate and fat, on calcium absorption. With

a calcium intake of 630 mg. per day, a protein intake of 100 to 130 gm. resulted in the absorption of 94 mg. of calcium, whereas on the lower protein intake of 45 to 70 gm. per day only 32 mg. of calcium were absorbed. Thus calcium absorption was about three times as great on the higher protein intake. This observation fits in well with the fact that lean meat has a definite antirachitic effect and that skim milk decreases the vitamin D requirement.

It should be pointed out that generally in thinking of bone growth and nutrition one is apt to think principally of calcium, phosphorus, and vitamin D, and it should be recalled that bones have an extensive protein matrix. This protein matrix is equally necessary for proper bone formation, maintenance, and repair. It is a common clinical observation to find adults who have a low calcium intake and yet have no demonstrable findings of calcium deficiency, though frequently such individuals have a high intake of protein. In spite of a low calcium but high protein diet, the Eskimo possesses excellent teeth and bones. Thus there is evidence that a good level of protein in the diet may convert an otherwise poor calcium diet into one supplying sufficient amounts of this mineral.

There is considerable evidence that a relationship between protein metabolism and the vitamin B-complex exists. Recent additions to the experimental evidence supporting this relationship are the findings of Perlzweig and co-workers⁶ that in rats and dogs, high protein diets favor retention of riboflavin and of niacin as judged by urinary excretion studies and also by actual tissue analyses for these vitamins in animals on low and high protein diets. As far as we know, investigations on human subjects with regard to absorption or retention of riboflavin or niacin have not been done, but it is

possible that, as in the case of calcium, a diet high in protein may favor retention of riboflavin and of niacin, and hence assist in securing adequate amounts of these nutrients from a dietary regime in which, in other circumstances, the amounts of these vitamins would have been suboptimum.

Have present wartime food conditions in this country posed special problems with respect to protein foods and the *health* of the people? It is our belief that the answer to this question is definitely no. True, certain protein foods are rationed and others may be rationed, but as long as this country has access to a plentiful supply of calories, and a variety of whole grain cereals and legumes, it is most unlikely that *impairment of health* from protein deficiency will ever occur. But there are very definite economic problems, as evidenced recently by the plentiful amount of livestock on the western ranges and the amounts of meat available at consumers' markets. And there are definite psychological problems of convincing a population used to eating a high protein diet that one of much lower protein content, and low in animal protein, will not necessarily impair health. Lumberjacks may demand plenty of red meat to get timber cut, but that demand rests on habit and not on a nutritional or medical basis.

Post-war feeding operations in war-torn countries will demand large amounts of protein foods until the agricultural economy of those lands can be restored to such a level that they can contribute effectively to their own nutritional support. But there are protein foods that could be made available in this and other countries; protein foods which are stable and of which stock piles could be created for the time when they are needed in large amounts; protein foods which are superior not only in protein but in other

essential nutrients. We refer specifically to wheat germ, corn germ, yeasts, dried legumes, and the various products which can be made from peanuts and soybeans. There is sufficient experimental evidence in animal nutrition that the vegetable proteins we have mentioned are high quality proteins. They have an excellent supplementing quality among themselves and when used with the more common vegetable proteins—and man does not live exclusively off of any one or two proteins. We do know that when properly prepared these superior vegetable proteins are well digested by human beings. True, their adequacy for human nutrition is in most cases not well known, but let us not reject them because of this. It seems to us that all too frequently there is far too much of a lag between research findings in animal nutrition and their application to human health. On the other hand, it is equally unfortunate, in the absence of experimental data, to proclaim that any of these lesser used protein foods are definitely superior in human nutrition to the more common protein foods on which we have considerable data.

SUMMARY AND CONCLUSION

1. The protein requirement of man cannot in the present state of knowledge be quantitatively stated in terms of amino acids, under certain standardized conditions.

2. Calorie intake from carbohydrate and fat spares protein, and in the presence of sufficient calories from non-protein sources, the amount of protein in the ordinary diet of an active adult may be safely reduced to 50 gm. per day, of which as little as 5 gm. may be in the form of animal protein. The experimental evidence supporting this latter statement is limited to an 8 week observation period; however, there is no reason to suspect that it would not hold for much longer periods. The recent findings of Youmans support this view.

3. The protein requirement is not increased in exercise, and physical fitness and efficiency are not impaired or improved on low protein diets adequate in other nutrients.

4. Substituting protein for some of the carbohydrate in the common American breakfast is a feasible way to prevent mid-morning symptoms of fatigue.

5. High protein diets are not harmful to the normal adult and are of definite therapeutic value in many diseases and particularly in convalescence.

6. Certain less common protein foods exist which are of high nutritional value, and which could be used with considerable value in post-war feeding operations.

7. We should not forget that protein foods are excellent sources of nutrients other than protein, and we cannot reduce the protein of a diet unless at the same time we provide the other essential factors contributed by protein foods.

Studies on Epidemic Diarrhea of the New-born: Isolation of a Filtrable Agent Causing Diarrhea in Calves*

JACOB S. LIGHT, M.D., AND HORACE L. HODES,
Lt. MC, USNR

Harriet Lane Home of the Johns Hopkins Hospital and Department of Pediatrics of the Johns Hopkins University; and Sydenham Hospital, Baltimore City Health Department, Baltimore, Md.

DURING the past two years we have had the opportunity of studying six separate epidemics of diarrhea of the new-born occurring in three hospitals in the Baltimore-Washington area. This study has been approached from the standpoint of a possible filtrable agent etiology of the disease.

The first two epidemics occurred almost simultaneously at two Baltimore hospitals in the early fall of 1941. Stools, blood, and nasal washings were obtained from a number of the babies and injected by various routes into a variety of the smaller animals. No definite disease resulted in any of the animals.

The subsequent four epidemics occurred during 1942, two of them in the full-term nursery of a Baltimore hospital and two in the premature nursery of a Washington hospital. All four were characterized by a high morbidity rate; in the last three of these epidemics the mortality was high, while in the first, occurring among full-term babies during the month of March, the mortality was low. Stool cultures were uniformly negative for known diarrhea-

producing organisms. In each of the four epidemics, stool of affected babies was given nasally to a calf. This material was Seitz filtered in three of the instances, unfiltered in the fourth. In all four instances there followed in the calf a bloody, mucoid diarrhea with comparable incubation period and clinical characteristics.

On the first occasion in which this result was obtained in the calf, the question arose as to whether attempt at further serial calf-to-calf passage would be worth while. The calf, like the human infant, is naturally prone to diarrheal episodes from a variety of causes, and the mere occurrence of diarrhea following injection in a calf would not necessarily signify that successful passage had been carried out. However, in view of the presence of blood and mucus in the stools of this first calf, it was hoped that if there were an agent here which could be passaged, the clinical picture in the calf might be distinctive enough to provide fairly reasonable assurance of successful passage. This hope has apparently been realized; successive calf passages were found readily possible with each of the four strains and the results of cross-immunity studies have indicated that the four strains represent a single agent.

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

Up to the present time this disease has been produced in a total of 84 calves. In the case of the first strain there have so far been carried out 29 successive passages, 10 of which were with filtered material; with the second strain 4 successive passages, 2 of them filtered; with the third strain 8 successive passages, 6 filtered; and with the fourth strain 2 passages, both filtered.

The majority of the calves used have been of the Guernsey breed, and these were found quite satisfactory. In Holstein calves the disease did not seem quite so typical and one Holstein calf was apparently not susceptible. Aside from this single animal, the calves used were found uniformly susceptible. Ages of the animals ranged from 2 days to 2 months. Most of them were in the 1 to 3 week age period, and in calves older than this the clinical disease tended to be milder.

Passage material consisted of saline suspension of infected calf stools obtained during the acute stage of the disease. The material was frozen when obtained and stored in a dry ice container until ready for use, then thawed at 37° C. and given by simple nasal injection. The minimum dose uniformly successful in passage was 1.0 ml. With Seitz filtrate preparations of this material a larger dose was necessary, the smallest successful dose ever used being 8.0 ml. Material given nasally to the unanesthetized calf is swallowed and it may be that the portal of entry for the agent is actually within the gastrointestinal tract, as the one attempt made at passage through the use of a stomach tube was successfully accomplished.

The clinical disease in these calf-to-calf passages was quite similar to that which followed the injection of material from the babies in the four epidemics mentioned above. The incubation period regularly ranged from 2 to 5 days. The disease itself, though ex-

hibiting a certain amount of variability, was uniformly characterized by the occurrence of diarrhea with the production of mucus, usually in very large amounts. Almost every calf also showed blood in the stools at some time during the course of the disease. As a rule, constitutional reaction was minimal, and aside from mild dehydration and anorexia at the height of the process, the calves would usually not seem particularly ill. Temperatures were taken on a few of the calves and very little fever was found.

The disease proved to be of a peculiarly relapsing nature in the calf, and in rare animals the mucoid diarrhea actually became chronic. In those calves which survived, the total duration of the process varied from 8 to 54 days; in the average case the duration was in the neighborhood of 3 weeks. Most of the animals recovered, the mortality being about 13 per cent. Immunity was found to be present following recovery, large doses of active material then causing no disease.

On gross pathological examination both small and large intestine showed hyperemia, while the intestinal lymphoid tissue was swollen and the mesenteric lymph nodes appeared enlarged. Microscopically, there were found areas of infiltration of the intestinal wall with polymorphonuclear leukocytes and in one very severe case ulcerations of the mucosa, while the intestinal lymphoid tissue and the mesenteric lymph nodes appeared hyperplastic.

Three attempts were made at passage with the use of the blood of infected calves. The first attempt failed. The other two, made with blood taken from exceptionally sick calves during the latter part of the first week of the disease, were successful, and it is interesting that one of the calves that came down from this material had been inoculated by the subcutaneous rather than the nasal route.

Susceptible calves exposed to infected calves were found to acquire the disease by cross-infection. In a few of the instances the disease thus acquired was clinically very mild, with relatively prolonged incubation period, but in most of the cases the picture produced was quite typical.

In view of the fact that cross-infections could occur, it was obviously necessary to enforce strict isolation of animals used in this study. This was accomplished by isolating calves singly in a number of widely separated areas such as farms where there were no other calves present.

In a consideration of the probable nature of the agent discussed in this paper, one of the first questions that comes up refers to the possibility that it is present in normal infant or calf stools. In this connection, the stools of 4 normal calves were given nasally in large dose respectively to 4 different calves. No disease resulted in these animals. The stools of 8 normal newborn infants were similarly tested, a pool of stools from 2 separate babies being given to each of 4 calves. Again no disease resulted.

As to the properties of the agent, it was found to be readily filtrable through Seitz filters, and cultures of filtrates on various aerobic and anaerobic media have been uniformly negative. The longest series of successive Seitz filtrate passages that was attempted was 4, and this was successfully completed, each calf in the series receiving Seitz filtrate of the stools of the calf that preceded him in the series. In view of the fact that the agent was not found in the stools of normal calves, this would seem to indicate that it is self-perpetuating.

Activity is maintained for at least 2 months when the material is frozen at -70° C. and stored in dry ice. Material which has been dried from the frozen state seems to undergo attenuation, and when used in passage results in the pro-

duction of a very mild disease of short duration, with prolonged incubation period. This very mild disease produces immunity, as a subsequent inoculation with fully active material results in no observable disease. When the stools from this very mild disease are further passaged, 2 serial passages result in the reestablishment of full virulence.

Heat inactivation experiments, carried out by the submerged sealed tubes method, are as yet incomplete. The data so far available seem to indicate that the agent is not regularly inactivated by boiling for 5 minutes, but is regularly inactivated by boiling for 10 minutes. Heating at 70° C. for 1 hour apparently fails to inactivate the agent, but heating at 80° C. for 1 hour results either in complete inactivation or in attenuation.

Protection tests were carried out with the use of the sera of 6 babies recovered from the epidemic in connection with which the first strain of the agent was obtained. The data on these tests would require discussion too lengthy for the present occasion, but, in brief, it appeared that two of the sera showed complete protection, two showed probable protection, and two showed partial protection. In this connection, with reference to the antigenicity of the agent, a rabbit was given repeated small intravenous injections of Seitz filtrate of infected calf stool. Following this his serum showed protective antibodies. This experiment was controlled by the use of serum from a non-injected litter mate.

The question arises as to whether this disease occurs naturally among calves. The opportunity came up to study two herds of dairy cattle more or less chronically infected with calf scours. In one of these herds a calf was found whose clinical picture was quite similar to that of the calves infected with the agent described above.

The studies which were carried out, however, indicated that the cause of his disease was not this same agent, and at the present time it is impossible to say whether or not this disease occurs naturally among calves.

In this connection, another question comes up which refers to the possibility that this agent might actually be identical with the pneumoenteritis virus, isolated by Baker¹ from a natural disease of calves characterized clinically by pneumonia and diarrhea. Though samples of this virus were not available for experimental comparison, it seems unlikely on the basis of the evidence at hand that the two agents are the same, first because of the absence of

pneumonia in the calves affected by the agent discussed in this paper, and second because of failure with it of transmission to mice even after a number of serial mouse passages.

The conclusions which seem justified from the data presented are:

1. In connection with four separate epidemics of diarrhea of the new-born a filtrable agent has been isolated which regularly produces diarrhea in calves.

2. In the attempts so far made, this agent has not been isolated from the stools of normal infants or normal calves.

3. The evidence suggests, though it is not conclusive, that the agent may be a cause of epidemic diarrhea of the new-born.

Streptococcal Infections in a Naval Training Station*

FRANCIS F. SCHWENTKER, LT. CMDR. MC, USNR, HORACE

Rockefeller Naval Research Unit, U. S. Naval Training Station, Bainbridge, Md.

WHENEVER an epidemic of streptococcal infection strikes a civilian population group, it is practically always caused by some single strain of streptococcus of high disseminating ability, either one already present which has recently increased its distributing powers or one newly introduced into the community from without. Endemic infections, on the other hand, are usually due to a number of different types of low disseminating ability which are part of the streptococcal flora of the community.

Since civilian communities are relatively static in composition, the changes in the streptococcal flora take place slowly. Outbreaks are infrequent and usually limited to the immediate population group. During wartime mobilization and training of troops, however, the conditions are entirely different. Men from diverse communities are collected into camps and stations; the opportunity for importation of some highly active strain or strains is therefore great. Furthermore, the men are housed by groups in barracks and congregated in mess-halls and

drill sheds so that the chance of dissemination of any strain of streptococcus is multiplied.

For this reason, we have undertaken a study of streptococcal infections in a naval training station for the purpose of gaining a better understanding of the epidemiological principles involved under these conditions and with the hope that some control measures might be developed.

At the naval training station raw recruits were formed into companies of approximately 125 men for a period of 10 to 12 weeks' training. Two such companies were housed in each barracks, one to a floor. Although each company was trained largely as an individual unit, there was frequent opportunity for contact between companies in mess-halls, drill sheds, and at recreational gatherings.

A representative company in its third week of training was chosen for the study which began on April 2 and terminated on May 7, 1943. A special history form was prepared for each man and all pertinent data were entered as collected. Throat cultures for streptococci were taken from each man on the first day of the study and twice a week thereafter. Sick call was held at 8 a.m. every day and any illness noted. Where

examination showed a respiratory infection, a throat culture was taken. All streptococci recovered, whether from the regular surveys or from cases of illness, were grouped, and if group A were typed by Lancefield's methods. A Dick test was done on each man at the beginning and end of the study period.

During the period of the study, 42 cases of streptococcal infection developed in the company. This actually represented 40 men, since 2 men each had two infections at different times. The incidence of streptococcal disease among the total 131 men in the company was therefore 32 per cent. This figure is high, but it includes all

cases of streptococcal infection which occurred, no matter how mild. Actually, only 14 of the 42 cases were of sufficient severity to require bed care. Nevertheless, the fact is demonstrated that streptococcal infections may be much more widely spread than usual morbidity figures indicate.

In Table 1 are shown the various kinds of streptococcal illnesses which developed and the streptococcal types involved. Six different types were responsible for sickness in the study company, but of these types 6 and 1 were outstanding. Together they accounted for 30 of the 42 cases of infection. The remarkable point is that,

No strains of types not included in table were isolated.

despite the large number of other streptococcal infections due to these two types, they caused no scarlet fever. The two cases of scarlet fever which did occur in the company were both due to type 3 streptococcus. This suggests that types 1 and 6, although highly pathogenic, may have only slight if any ability to produce scarlet fever.

More evidence on this point is available in Table 2, in which is given the percentage distribution of the different types among streptococci recovered from various sources on the station. The first point of interest in this table is that the percentage distribution of the various types of streptococci in the study company is the same among cases of illness and normal carriers. This confirms an observation we have previously made¹ in a study in an army camp that the incidence of disease due to a given type is proportional to its distribution among normal carriers. Furthermore, the distribution of the various types among normal carriers in six other companies on the station was practically the same as in the study company, so that the latter may be considered representative of conditions on the station as a whole. In all of the companies types 6 and 1 predominated. Nevertheless, among cases of scarlet fever occurring on the station, types 3 and 19 were outstanding. No cases of scarlet fever due to type 6 were discovered, and only two were caused by type 1. This is evidence that types 6 and 1 had negligible power to produce scarlet fever.

It seems, therefore, that the streptococci present on the station could be divided into two major kinds:

1. Types which were highly pathogenic but which had little scarlatinogenic ability, like types 1, 6, and 12.
2. Types which were pathogenic and scarlatinogenic, like types 3 and 19.

No reason has yet been discovered why some strains are scarlatinogenic and others not. Julia M. Coffey of the

Division of Laboratories and Research of the New York State Department of Health was kind enough to determine the toxigenic abilities of the four major strains encountered. Types 19 and 6, one scarlatinogenic and the other non-scarlatinal, each produced toxins of high potency, approximately 90,000 S.T.D. per ml. On the other hand, types 3 and 1, the former scarlatinogenic and the latter not, yielded toxins of only low titer, approximately 100 and 1,000 S.T.D. per ml, respectively. Even admitting that a laboratory test may not give a true indication of the ability of a strain to produce toxin under natural conditions, the fact remains that type 6, which produced no scarlet fever, possessed the ability to produce toxin of extremely high potency. It appears, therefore, that toxigenic ability alone does not determine the difference between a scarlatinal and a non-scarlatinal strain of streptococcus. This problem will need considerably more work before it is clarified.

During the period of the study throat cultures were taken on all normal persons in the study company at semi-weekly intervals. The carrier rates for the various types of streptococci recovered have been charted in Figure 1. Type 6 was the predominate strain; from 16 to 33 per cent of the men were carriers of this type. The second most common strain, type 1, showed carrier rates between 7 and 18 per cent. The three other outstanding types, 3, 19 and 12, averaged 5, 4 and 4 per cent respectively. When all types are considered the carrier rates ran as high as 69 per cent.

The striking point in these observations is the high carrier rates. Ordinarily in normal civilian populations the rates are not over 10 per cent, and even during epidemic times rarely exceed 40 per cent. But in this case, as high as 69 of every 100 individuals were carriers of streptococci and 66

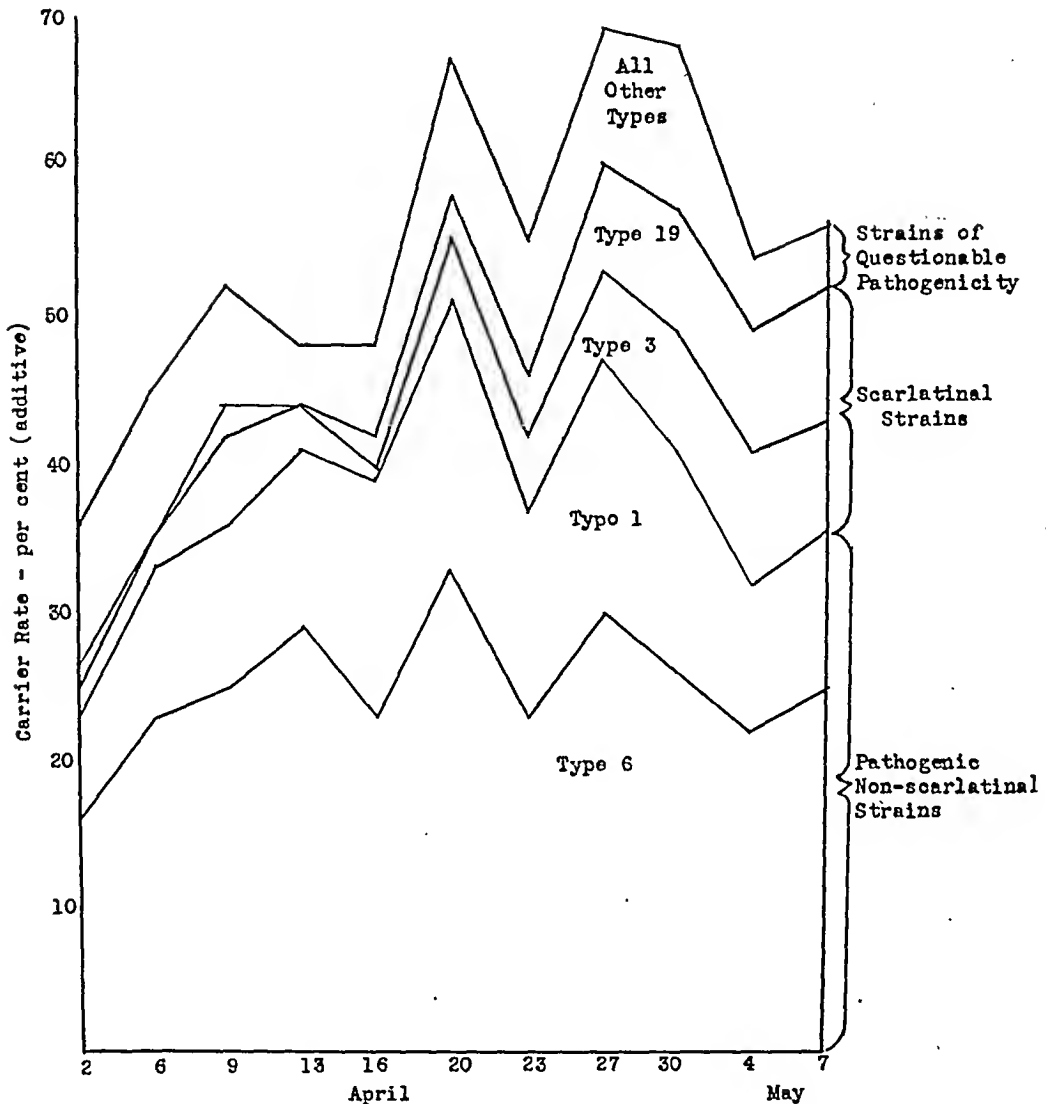

FIG. 1. THE COMPOSITION OF STREPTOCOCCAL CARRIER RATES IN THE STUDY COMPANY DURING THE PERIOD OF STUDY.

of these harbored strains of known pathogenicity.

These high carrier rates account for the high incidence of streptococcal infections in the study company. As previously mentioned, we have demonstrated in an earlier study¹ that during an epidemic of scarlet fever due to a single type the case incidence in various companies was proportional to the carrier rates for the type of strepto-

coccus causing the outbreak. In the present study, however, we have an outbreak due to a number of different types. If we plot the average carrier rate for each type during the study period against the case incidence of illness due to the respective type we find the relationship to be a straight line (Figure 2). This means that where more than one type of streptococcus is active during an outbreak, the number

of cases of infection due to each is proportional to the carrier rate for the respective type.

These high carrier rates apparently developed among the men during their course of training, since only 4 per cent of incoming inductees were found to harbor beta hemolytic streptococci.

The next phase of the study concerns the experiences of the individual men with the streptococci. Eighteen of the 131 men in the study company were never reached by the streptococcus, and therefore naturally developed no illness. From 113 men, streptococci were recovered by throat culture; in many instances two, three, and even five types were found in the same man during the study period. And yet only 40 men developed streptococcal illnesses. What protected the other 73 men definitely known to have streptococci in their throats from becoming sick? Time will not permit a full analysis of the observations on this point. They will be

made the subject of another report. The following are, however, the important points:

1. Seventy-three men developed no illness even though as many as five different types of streptococci of known pathogenicity were recovered from their throats.

2. The Dick reaction apparently played no rôle in this resistance, since the amount of illness among Dick negative men was proportionately the same as among those Dick positive.

3. Some individuals resisted infection with one type of streptococcus but became ill when seeded with another type.

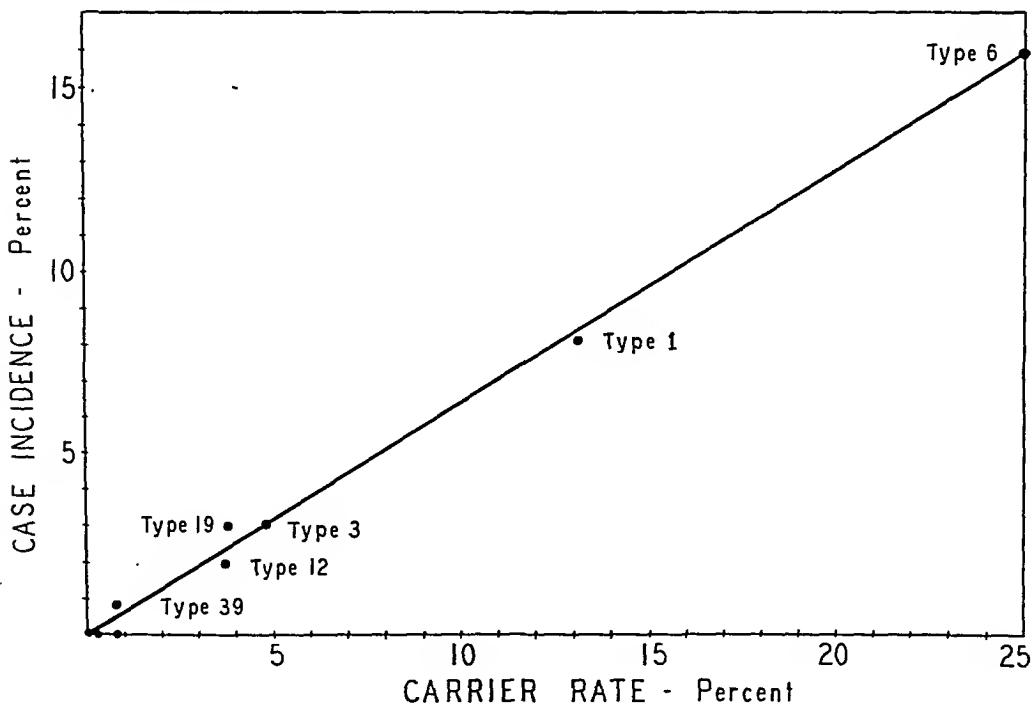

4. Several persons developed two illnesses due to two different types of streptococci.

5. No person became ill twice from the same type organism.

All of these observations point toward a conclusion that resistance to streptococcal infections is due, at least in part, to some form of type-specific immunity.

These studies have, therefore, pointed out two possible avenues of approach to the problem of preventing streptococcal infections at naval stations. First,

FIG. 2. The relationship between the percentage distribution of various types of streptococci among normal carriers and among cases of illness. Each dot represents a type of streptococcus

since the number of cases of illness is proportional to the distribution of streptococci among the men, steps aimed at preventing or inhibiting the dissemination of organisms should lower the number of infections. Studies in this direction are under way but as yet incomplete.

Second, since resistance to infection seems to be type-specific, it may be possible to develop a type-specific immunity to those types which are active on the station. Studies are therefore being made on the development of efficient type-specific vaccines. The method would not be applicable for universal use, but at stations where only a few types are responsible for the streptococcal illnesses, a pooled vaccine of these types, given to all incoming recruits, may prevent the bulk of the streptococcal disease. Our work in this direction is so far encouraging but awaits the test of trial during the coming winter.

And finally prophylaxis with sulfonamides should not be overlooked. Our previous report² on this subject has demonstrated that streptococcal epidemics may be controlled by the

administration of small doses of sulfonamides, and that the resultant drop in case rate holds for at least 3 weeks following discontinuance of the drug.

The prevention of streptococcal infections in the armed forces may not, at first glance, seem important except in those instances where a definite epidemic occurs. They are, however, constantly present, especially during the winter months, and although not reflected in the usual morbidity figures because of their general mildness, they account for a very appreciable figure in man-days lost.

Laboratory Methods Used in Determining the Value of Sulfadiazine as a Mass Prophylactic Against Meningococcic Infections*

COLONEL DWIGHT M. KUHNS, M.C., USA, AND
CAPTAIN HARRY A. FELDMAN, M.C., AUS

Fourth Service Command Medical Laboratory, Fort McPherson, Ga.

THE purpose of this paper is to outline the laboratory methods used in evaluating the efficiency of the mass use of sulfadiazine as a prophylactic against meningococcic infections and to describe the laboratory studies that should be made before such treatment is instituted. As is generally known, meningococcic infections presented a considerable problem during the past winter in the various newly assembled Army camps in the southeastern United States. The control measures that have been used heretofore, such as isolation of patients, quarantining of units, and culturing of contacts had no noticeable effect upon the prevention of additional cases. It was shown that only rarely would the new cases occur among the contacts of diseased individuals. Sample surveys of military units where meningococcic infections were occurring indicated that a high carrier rate, with Group I carriers predominating, was present.

It was decided, after preliminary trials proved that small doses of sulfadiazine were effective in sterilizing meningococcus carriers,¹ to determine the efficiency of the mass use of this

drug for controlling meningococcic infection by the total elimination of carriers. A preliminary report concerning these studies has been rendered elsewhere.² This showed that the administration of small doses of sulfadiazine to an entire population *at one and the same time*, is the most effective means available for controlling meningococcic outbreaks in closed populations. The carrier rate is precipitously dropped to near-zero and this is immediately reflected in the case rates.

But who shall receive such treatment? As was mentioned before, the culturing and treating of case contacts is of little value. Even though sulfadiazine was found to be effective in eliminating carriers from an entire population by the mass prophylactic use of the drug, the measure should not be applied indiscriminately to large groups without first making a careful epidemiologic study. This should include determinations of the carrier rate, as well as of the serological types present. Our studies have shown that when epidemics of meningococcic infection occur, the following conditions are present: high carrier rates, predominance of Group I organisms, and the presence of non-immune (new recruits) individuals in the population. Table 1 summarizes the data collected from

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

A	37.0	56.8	5.4	1.4	36.4	Epidemic	Yes
B	55.8	62.2	7.5	7.3	23.0	Sporadic	No
C	7.9	11.2	7.4	18.6	62.8	No cases	No

* Polyvalent meningococci

several camps and demonstrates the above conditions. Such data give one economic as well as epidemiologic justification for the treatment.

The description of the methods evolved from these studies forms the basis of this report. These methods have now been employed in 4,737 carrier and case cultures obtained during the past 9 months. Of this total, 1,692 were positive for meningococci (Table 2). Of the positive cultures, 800 were obtained from the blood and spinal fluids of actual cases of meningococcal infection. These were examined by the methods to be described, and form the basis for our acceptance of their worth. In no instance have we encountered an organism, actually isolated from a patient, which failed to type serologically or to yield the typical fermentation reactions. These results are a reflection of the vastly improved media (dehydrated) and typing sera available today. Although these procedures are relatively easy to apply, good results can only be obtained by well trained

personnel. One should take every opportunity to increase his efficiency by practising with known meningococcus cultures which have been mixed with ordinary throat cultures.

At this point it might be pertinent to define what we have called a meningococcus: a Gram-negative diplococcus which ferments dextrose and maltose but not sucrose, and which is agglutinated by polyvalent horse, anti-meningococcus serum but not normal horse serum or saline. Agglutination by monovalent rabbit serum is desirable but not necessary except for the requirements of specific type identification. We have encountered organisms in carriers but not in active cases which fulfil all of these criteria, except that they are agglutinated only by the polyvalent horse serum and not by monovalent rabbit (or chicken) sera. We call such organisms "polyvalent meningococci," and believe them to be deficient in capsular substance as might be expected in carriers.

Further, these organisms should not

* Polyvalent meningococci

† Carrier Surveys predominately

grow at room temperature but should require rather fastidious growth conditions such as enriched media and the diminished oxygen tension of the candle jar. We routinely include para-aminobenzoic acid in 5 mg. per cent concentration in all of our primary isolation media as a safeguard against sulfonamide treated patients.

METHODS

1. *Culture media:*

a. *Chocolate Agar:* This is a mixture of dehydrated hemoglobin (Difco) and Proteose No. 3 Agar (Difco) made according to the instructions of the manufacturer³ except for the addition of 50 mg. of para-aminobenzoic acid per liter.

These plates should be incubated for 24 hours following their pouring, and those with contaminating colonies discarded. The plates should be moist but not wet. If too moist, difficulties with contaminants such as proteus may be pronounced. They should be warm when inoculated; following this, they are transferred to candle jars and incubated at 37.5°C. Chilling must be prevented. Many of our surveys were done under field conditions but the plates were kept warm by wrapping with blankets.

b. *Fermentation Medium:* The medium to be described has been found extremely effective for both meningococci and gonococci. Reactions may usually be read in 12 hours or less for the former, while the latter may require 48 hours. Spinal fluids may be inoculated directly into this medium. Because of its agar content, the oxygen content is kept low enough so that incubation in the candle jar is usually unnecessary. We employ three sugars routinely: dextrose, maltose, and sucrose. An occasional meningococcus will ferment dextrose or maltose slowly but all have eventually fermented both. Sucrose fermentation has not been encountered in our series.

Formula

Bacto-tryptose	20 gm.
NaCl	5 gm.
Agar	1 gm.
Phenol red	0.4 ml. (0.2% stock solution)
Distilled H ₂ O to	1,000 ml.

Adjust to pH 7.4.

Add 5 gm. of dextrose or maltose or sucrose to 1 liter of medium. Sterilize for not more than 10 minutes at 10 lb. of pressure.

The consistency of the fermentation reactions obtained with this medium clearly establishes them as valuable adjuncts for the final identification of *Neisseria*.

c. *Serological Typing:* Quellung⁴ reactions are not feasible in carrier surveys. The spot-plate method to be described is rapid, accurate, and economical. It was run in parallel with the macroscopic tube agglutination for several hundred specimens and no discrepancies were encountered. We have used it for both our case and carrier cultures.

Serum: Typing and control sera diluted 1:10 with normal saline are employed.

Suspension: The surface of a plate containing a pure growth (by Gram-stain) of the organism to be tested is wiped with a cotton swab. This is then plunged into a small tube containing about 0.5 ml. to 1 ml. of normal saline, and twirled until a smooth, fairly dense suspension of organisms results.

Test: Several circles are marked with a china pencil on a large glass slide. One drop of each of the sera is placed in its circle. A drop of the suspension is added, and complete mixing is accomplished by stirring with a toothpick. The slide is then rotated gently for 15-30 seconds. Agglutination is read macroscopically, preferably by indirect illumination against a dark background. Final readings should be made before there is any sign of drying. Agglutination is readily observed when present.

If an organism agglutinates in all the sera, then, providing that a pure culture

has been used, it is probably not a meningococcus. However, an occasional meningococcus may be "serum-sensitive." These should be replated and retested the following day. Contaminated cultures which give improper agglutinations may be purified in this way. By that time, also, the fermentation reactions will have been completed and further indication of its identity will have been obtained.

Approximately three hundred organisms were typed in duplicate by the spot-plate method with both rabbit and chicken⁵ sera.* In no instance was any disagreement noted between the two. Those organisms which were agglutinated by polyvalent horse serum but not monovalent rabbit serum were also not agglutinated by chicken serum. It is our belief that the rabbit and chicken sera may be used interchangeably.

d. *Routine for Carrier Surveys:* A curved wire swab, which has been slightly moistened with a few drops of broth, is passed up and behind the uvula and the posterior nasopharynx is wiped gently. This swab is then removed without touching the tonsils or the buccal linings, and is streaked across one-eighth the surface of a chocolate-agar plate. The wire swab is discarded. Using a fresh sterile, wooden swab or a platinum needle the remainder of the plate is streaked from one contact with the original streak. The plate is then transferred to a candle jar and incubated for 18-24 hours.

Following this period of incubation, the plate is removed and searched for suspicious colonies. These will ordinarily be seen in the secondarily-streaked area as moderate-sized colonies somewhat opaque, moist, soft, and easily emulsifiable. They may be completely clear. Three or four suspicious colonies are picked to a "pie-plate"

(another chocolate plate which has been divided into four or eight parts). This increases the chances of finding multiple types in a single carrier. We have isolated two types from one carrier on several occasions. It cannot be emphasized too strongly that the examiner should practice such isolations with known cultures on every possible occasion. One can easily double the percentage of his positive findings as the result of practice. The "pie-plates" are placed in the candle jar and incubated at 37.5°C. for 24 hours; at the end of this time they are removed and examined for purity. If they are pure cultures of Gram-negative diplococci, they are inoculated into sugars, and also agglutinated by the method previously described. The sugars will usually be completed within 12 hours. An occasional organism will ferment either dextrose or maltose slowly, and these may require slightly longer incubation.

It must be borne in mind that the meningococcus grows very profusely on this medium and produces colonies of fairly large size. This is sharply contrasted with the gonococcus which grows much slower and produces colonies which are much finer.

Some carriers will present what looks like pure cultures of meningococci, but one must guard against the tiny, *Hemophilus* colonies which may unnoticeably be transferred with the *Neisseria*.

We have not employed the oxidase⁶ reagent on a wide scale since it was felt that with experience one could pick suspicious colonies with considerable accuracy, and therefore it was not necessary to use this reaction.

Utilizing the methods described, one may do fairly large scale studies on an accurate basis without too much difficulty. If one desires, the fermentation reactions can be omitted and final identification can be made on the basis of serological reactions. However, fermentation reactions should be deter-

* Supplied through the courtesy of Dr. W. V. Verwey of Sharpe and Dohme, Inc.

mined whenever there is any doubt concerning a given culture.

In closing, we would like to stress again that, before chemo-prophylaxis is employed on a large scale for a given group, a survey along the lines indicated in this paper should be made if proper laboratory facilities are available. The fact that one or two cases occur in a certain group is by itself, insufficient ground for wholesale distribution of sulfadiazine. A proper survey will help to indicate the probability of future cases and, therefore, the necessity for chemo-prophylaxis.

CONCLUSIONS

1. A routine which employs dehydrated media, a simple candle jar, and a rapid serological technic has been described for facilitating studies for meningococcus carriers.

2. The relationship of meningococcus carrier surveys to the mass treatment of such carriers with sulfadiazine as a method for controlling epidemics of this disease has been stressed.

MEDICAL CARE MUST BE COMPLEMENTED BY PUBLIC HEALTH MEASURES

IN Congressional, sociological, medical, and public health circles there continues to be a lot of discussion of the medical aspects of the Wagner-Murray Bill which, according to its proponents would make good medical care freely available and according to its opponents would play havoc with medicine and medical care. Be that as it may, there seems some possibility that the medical features of this bill may be passed by the Congress for want of something better; and passage is rather likely if an increase in the rate of social security pay roll deductions is adopted as an anti-inflation measure.

Most thoughtful people agree that it would be unsound, as a public policy, to mix social security legislation and anti-inflation measures, even though this might at the moment seem expedient and popular. But suppose that in spite of this objection and regardless of the grave apprehensions many have about the medical aspects of the bill, it should be passed and really did provide a decent and extensive medical service. Even this would get the medical profession and the public no further forward than medical care of the individual if, as, when, and after he becomes sick; and this is not enough. Care of the sick is only a half measure, and in any planning for the health of the farmer in the field and the industrial worker in the factory, medical care must be buttressed with or complemented by a public health program sufficiently great in its scope and intensive enough to bring to the people of all communities the full benefits of preventive measures. It follows then that if the Wagner-Murray Bill or some other bill should be passed, or even if no bill at all is passed, there must in any event be a thumping increase in the amount which the public pays for the maintenance of its health.

To expect health agencies, operating on present miserable appropriations, to bring to the people the full benefits of modern science is to expect the impossible; and health administrators will be rendering no service to their cause or to the people for whose health they are responsible if they remain satisfied to act the rôle of remittance men. The time has come, or rather it came some years ago, when health officers need to say boldly that it costs real money to do decent public

health work, that the budget for a properly operating health program is not just an infinitesimal part of government expense. Probably one of the reasons why health department budgets are so small is that each health officer has emphasized to his appropriating body how little he asks in comparison with education, roads, parks, police, fire, etc. These more robust elements of government could employ the same argument if they were willing to conduct their activities on a nineteenth century scale. But they are not willing to do this, and they do get the funds. In the rough and tumble of affairs, humbleness is not normal nor is it either admirable or result-attaining.

It would seem well to state here that this emphasis on the urgent necessity of provisions for a substantial increase in appropriations for public health work does not arise from any tendency to deprecate the importance of the care of the sick; nor does it arise as part of an argument that prevention may entirely replace cure. Beyond a doubt, the world will always have its sick and probably some poor, in spite of all that science or society may do, and if one is realistic, this must be accepted. But with each succeeding generation there has been and there should continue to be an increase in the possibilities of prevention through public health measures, and from the standpoint of economy in time, money, and suffering, measures of this sort must be continually explored, expanded, and applied in association with service designed to care for the sick.

Now it has been suggested that there be included in the Wagner-Murray Bill (just in case it should pass) a provision that would insure reasonably adequate and specifically designated funds for state-aid in public health work, say some ten per cent of that amount which would be set aside for medical and hospital care. No one knows exactly how much the total Medical Care and Hospitalization Account would be, under this bill, but it is reasonably safe to say that ten per cent of it would loom large in comparison with present federal expenditures for public health purposes. Unfortunately it would not seem practicable to put this suggestion into effect, for funds raised under social security are contributed funds, ear-marked for the benefit of those who contributed them. Such funds could not be used for an over-all benefit to all the people of the nation unless all the people contributed, and the Wagner-Murray Bill does not propose that every person contribute. Such an impasse, however, does not offset the soundness of the proposition that medical care without adequate provision for public health programs would be but a half measure, and if this concept were to be accepted by Congress, its members could find ways and means.

In effect then this may be said: The Wagner-Murray Bill is alarming in its social implications. It has much that is sound in its medical provisions but at the same time contains many positive and negative deficiencies. We should be unhappy to see it pass in its present form, but if it is to be passed there should be made whatever adjustment is necessary in order to set aside from its derived funds a proportion sufficient to insure effective public health programs; and the proportion necessary to achieve this would be no mere pittance.

THE PUBLIC'S FOOT

ONE of the difficulties in getting people to take action in any given direction is that human beings are almost certain to miss the significance of a simple declarative sentence, or of a routine happening. To catch attention there must

be some emphasis by tone or inflection or accent or play on words, or some drama or association, or climax. In contrast to a flat declaration, consider the statement that "An army marches on its stomach." Here there is association between this truth in metaphor and the somewhat ridiculous mental picture that it creates. From this association comes remembrance, and remembering, one ponders. But if the statement is "The public walks on its feet," or if the observer notes that this is so, the listener or reader or observer is unimpressed. The information obtained is not news, nor is it dramatically presented. It appeals neither to the esthetic nor the intellectual, and it fails to arouse either sympathy or afterthought.

Even if "The public walks on its feet" is an unimpressive statement, the fact that man does so walk, rather than on feet and hands, has created a far-reaching public health problem. For though structurally and functionally the foot is an amazing mechanism, it is not yet completely adapted to the erect posture. Nor is the bony skeleton of one person's feet so exactly like another's, or the amount and distribution of downward pressure so much the same that, proper width and breadth assured, the ordinary stock shoes are suitable for all people. The net result of these various contributing factors is foot trouble for a large proportion of the public, just what proportion it is hard to say. No hard, cold, reliable data are available on this point, but common observation indicates that more than a majority of adults have one or another kind of foot pain, weakness, or impairment. If this were not so, bedroom slippers would not always be shown in pictures of the tired business man, relaxed at home. And if uncomfortable feet were not a part of woman's cross, there would be lots less pawing around for shoes in the dark of the moving picture theater.

It may fairly be said then, that foot discomfort and partial disability are relatively highly prevalent. At the same time it must be confessed that there are few places to which the foot sufferer may turn with any assurance of relief. Foot troubles do not kill, nor are they as a rule completely disabling, and the medical profession and public health workers are not inclined to give much thought to a disability which does neither of these things. Apparently the subject is beneath the notice of the high-powered orthopedist, and he will have none of it. Give him something that involves fractures, stiff joints, deformities, plaster casts and the adjustments of muscles, and he is your man; but go to the same orthopedist with nothing more serious, from his standpoint, than a callous, and he is not likely to be interested, and not assuredly competent. The average physician, for his part, lacks fundamental knowledge as to the complicated functional anatomy of the foot. He is not, therefore, in position to bring relief to the patient, and ends up by referring her or him to a shoe store or a chiropodist. This is not to suggest that physicians undertake the routine trimming of toenails or the cutting of corns. But it does seem worth emphasizing that pedal disabilities constitute a vast problem and a correspondingly vast demand for relief, and that since the medical profession is not meeting this demand, these sufferers are seeking aid and comfort in other directions. They thus create public support and, in some instances, legislative backing of those who, from the medical standpoint, must be regarded as irregulars and sub-professional, and therefore not a group to be encouraged. And, more important from the sufferer's standpoint, he gets only temporary relief, as a rule.

Another deterrent to serious consideration of the foot is that at its best, and even with red toenails, it is not a thing of which poets often write: of the ankle (female) yes; of the curve of the calf (female), higher and higher praise; but of

the foot, male or female, no. This is understandable, for to the casual observer, the foot is but a slewed-out, battercake-like extremity, with over-riding toes and a strong tendency to corns, callouses, and bunions. And so to the world at large the foot is not an inspiring subject and, unlike syphilis, has not been adopted by fashionable society as a drawing room topic. Each dowager and smart young matron tends to regard her own foot pains as personal, a bit on the vulgar side. Obviously, if the woman of leisure does not feel that this is a dilemma from which she must deliver her lesser sisters, the lesser sisters must continue to suffer surreptitiously, and so with the butcher, the baker, and the policeman on his beat. Not until these foot sufferers become as vocal and clamorous and objectionable as a militant minority, though they are not a minority, will the medical profession be moved to find an answer.

In spite of all these things, a few physicians have undertaken serious study of the comparative anatomy of the foot, of its evolution, its mechanics, of the effect of the erect posture and the pull of gravity on and through the foot. As nearly as can be gathered, these men have established relatively simple diagnostic procedures and quite effective therapy. Apparently, however, their pleas that the medical profession adopt a different attitude in regard to foot troubles, that it inform itself, and that it exercise modern diagnosis and therapy have fallen on deaf ears. And the suggestion that foot troubles constitute a public health problem is likely to strike horror in the hearts of the virus worker, the nutritionist, the administrator, the epidemiologist, unless they happen themselves to have some personal experiences along this line. But let it not be forgotten that the high incidence of a minor and lowly disability may constitute a more serious public health problem than does some aristocratic but comparatively rare disease.

Credit Lines

IT was a simple matter for the Editors to decide that this issue of Credit Lines would be devoted to the Association's Wartime Conference and 72nd Annual Business Meeting and Meetings of Related Organizations held in New York City, October 11 to 14. It was another thing to agree on where to begin and what to select for mention from among the events and personalities which together made an engrossing week.

It seemed safe to start with the delegates, who, after all, are the most important part of a convention. There were so many of them, 3,603 to be exact, that programs ran out by Tuesday noon and a supplementary mimeographed edition, done overnight, melted entirely away before lunchtime on Wednesday. This largest registration in the Association's history was solid-pack, professional public health workers, with little dilution by wives and guests. It may well have historic importance, if it is, as we believe, the largest number of professional public health workers that has ever come together anywhere in the world at any time. A claim to a "Famous First" is always immediately challenged, so we are guarded in making that statement. If anyone knows of a larger meeting—of professional public health workers now—we should like to be reminded of it. The American Health Congress, held in Atlantic City, N. J., in 1926, will not be accepted as a rival. While the attendance there was well over 6,000, the members of the American Nurses Association were largely responsible for it, so that does not count.

First and full credit, then, goes to the 3,603 delegates for good-naturedly accepting a program-less registration,

crowded meeting rooms, accommodations in hotels whose names they never heard of before, when the Pennsylvania, New Yorker and other nearby places were packed to the gunwales, and, most of all, for making the effort to come. They got their money's worth, thanks to the Program Committee who wrote the play and provided the actors, and to the New York Local Committee who produced it.

The production end of an operation as extensive and involved as an Association meeting isn't done with one hand tied behind the Chairman's back, nor with mirrors. Dr. Ernest L. Stebbins, as General Chairman of the Local Committee, and his subcommittees on Finance, Reception, Meeting Rooms, Radio, and Publicity, had their collective hands full. The real test of the effectiveness of the producing job is keeping secret from as many delegates as possible how much work is done before the curtain goes up and how much is done backstage while the performance is going on. Dr. Stebbins, Mr. Frank Kiernan, Dr. John L. Rice, Dr. John Oberwager, Dr. Iago Galdston and Dr. Frank Calderone, Chairmen in that order of the subcommittees named above, kept the secret well.

The Finance Committee raised the money to do all the things for which money was necessary. Only Lend-Lease Administration could afford to pay on a dollars-and-cents basis for the many work-hours contributed to the Conference by members and friends of the Association in and around New York. The Meeting Rooms Committee kept the Section Officers and the speakers happy, no small responsibility. The Reception Committee made everybody happy. The Publicity Committee, by

dint of superhuman effort, succeeded in drawing in more abstracts of papers than were ever acquired before, and by so doing, giving the local and national press more material to work with than ever before. By the way, a limited number of sets of abstracts were collated by the Publicity Committee in winding up its affairs. They may be obtained, (as long as they last) on request to the Central Office. The committee developed its work plan under the slogan "Health Is Global," and its initial effort was to gather in statements on this theme from state and territorial health officers, from many Latin American health leaders, and from the ministries of health of our Allies. These air-mailed, wired, and cabled responses are eminently quotable. They have been mimeographed as well and are included in the abstract packet.

The Radio Committee was responsible for the Association's first connection with a program as notable as America's Town Meeting of the Air, with its millions of Thursday night listeners. Debating the question "Are Local Health Services a Responsibility of the Federal Government?" Dr. Abel Wolman and Dr. Nathan Sinai, for the affirmative, and Dr. H. H. Bauckus and Mr. E. A. Van Steenwyck for the negative, provided several hundred Wartime Conference delegates, who attended the broadcast in Town Hall, and large numbers of Association members at their radios at home with an entertaining and thought-provoking hour. This was one of three coast-to-coast broadcasts. The other two were sent by short-wave as well to Latin America. The dramatization, "The Battle for Health," written by Mr. Irve Tunick for the Association, will be published in the January JOURNAL. It is offered for re-use by public health workers in whole or in part without restriction.

Credit Lines would be ungracious if it did not bow in the direction of the

Pennsylvania Hotel in acknowledgment of excellent service in spite of man power shortages and wartime restrictions.

The Program Committee, consisting of a small central group selected for over-all knowledge of and experience in public health and the Secretaries of the Sections, who, of course, represent special interests, was wholly responsible for the scientific content of the Wartime Conference. The fact that it was planning a program on wartime public health was not forgotten for a moment and the finished product of 176 papers and reports presented in 50 sessions turned out to be almost an encyclopedia of what the public health worker is doing, or at least should be doing, to meet problems posed by the war.

The play's the thing, perhaps, but as was mentioned before, the audience is important too, and the sustained interest of the delegates was nothing short of amazing. The final sessions on Thursday afternoon were as well attended as those in the early part of the week. One session on the last afternoon continued until 6 o'clock with not a rustle of impatience or an indication of saturation from the audience. Another at the same time went far beyond the usual 4:30 closing, with every one of the 450 chairs occupied and perhaps 200 persons standing or sitting on the floor. This was a special session entitled "The Evolving Pattern of Tomorrow's Health" where imaginative and exciting post-war planning was done with regard to housing, hemispheric coöperation, education, and health department responsibilities.

All the special sessions were high spots and there is evidence that many people are anticipating their publication in the JOURNAL as symposia. One on "Current Health Department Problems in War," under the leadership of Dr. Huntington Williams, used personnel shortages as a point of de-

parture. It was a panel session and by agreement no formal papers were prepared. Those papers describing "New Ventures Toward Health Security" and "Public Health Implications of Tropical and Imported Diseases" are awaiting the attention of the Editorial Staff. Four of the five papers comprising the post-war planning session appear in this issue.

There were interesting innovations in the technic of program building. Dr. Edmund K. Kline, Secretary of the Laboratory Section, experimented successfully with a session of what he called "abridged papers" under the title "What Is Happening in the Laboratory Field." In two and one-half hours, a large audience had the opportunity to hear 12 short papers, 5 to 7 minutes' presentation time, on as many subjects. A condition to being given a place on the program was the preparation of a full length manuscript for possible publication in the JOURNAL.

The new Section on School Health, in coöperation with the Food and Nutrition Section and the American School Health Association, sponsored a Workshop on "Adjustments of School Health Personnel in Wartime." Registration was requested in advance, admission was by card only, and the deliberately-chosen small meeting rooms with seating capacity of 50 assured the limitation of the size of the three groups. In an all day session, they attacked their problem as it relates to the rural, medium-size, and large community. The Maternal and Child Health Section, with support from the Food and Nutrition, Public Health Nursing, and School Health Sections, tried the Workshop idea, too, on problems connected with day care of children, with participants similarly limited as to numbers and self-divided according to their own interests, in state, large city, and small city groups.

The School Health Section, being

new, without committees and without commitments, used its Workshop as a device to determine its plan of work for the coming year. Since what could be done was so vast in its possibilities, focal points needed to be established. Dr. Leona Baumgartner, Chairman, and Dr. George M. Wheatley, Secretary, described the result as the emergence of islands here and there upon which school health people could scramble, look around a bit, and make up their minds what to do next. Task forces will carry out the decisions reached during the months ahead.

One could dip into the Section programs anywhere and come up with a nugget, as the JOURNAL will prove month after month as it brings the papers and reports to its readers. Meetings of related organizations held on Monday, October 11, were noteworthy, especially the symposium on cancer. It must be recorded that the first announcement of the dramatic results following the use of penicillin in syphilis was made at a meeting of the Epidemiology Section on October 14. Another good story, although it does not represent a world-premiere, was the use of penicillin in gonorrhea, read at the same session. Both papers, by Dr. John F. Mahoney, *et al.*, appear in this JOURNAL. In the January number, one or more of the contributions to a symposium sponsored by the Oral Health Group, now the Section on Dental Health, on Post-war Implications of Fluorine and Dental Health will be published. Immediately ahead, too, is Earnest Boyce's "Objectives in the Programming of Post-war Sanitation Work" which was part of a symposium arranged by the Engineering Section on post-war opportunities and responsibilities of the sanitary engineer. The Food and Nutrition Section has a reserve of excellent papers which the Editorial Board will find it difficult to put in any pub-

lication order, and this is true of all the Sections.

Streamlined as the Conference was, and without entertainment, social features, inspection trips, and other pleasant adjuncts to the real business at hand, there was neither time nor opportunity for the many breakfasts, luncheons, and dinners which have characterized Association meetings in the past. All alumni get-togethers were discouraged, for example, and reluctantly but in realistic answer to the question "What wartime significance does this have?" the Annual Banquet was omitted. There was one exception to the prohibition against purely social functions, and as if to make up for their lack, this was enthusiastically entered into. The Public Health Association of New York City sponsored the Reception to the President, President-elect, and Distinguished Guests which followed the opening General Session on Tuesday evening, and, aided and abetted by the Reception Committee, demonstrated a unique method of getting everybody acquainted with a minimum of formality and waste motion. The receiving line was dispensed with. Instead, great placards at intervals around the reception room announced that here were temporary headquarters for the Association Officers and Distinguished Guests; there the Public Health Association of New York City would receive; yonder were the representatives of State Health Departments—New Jersey, New York, and Connecticut; across the way stood the National Health Honor Roll Health Officers, and in the far corner the folks from the New York City Health Department. It was thus made easy for delegates to seek out the people they wished to see. After an interlude of hand-shaking and conversation, refreshments were served through the courtesy of the Lily-Tulip Cup Corporation. Door prizes were awarded and there was spirited compe-

tition among several quartets made up on the spur of the moment. They were singing not for their suppers but for a quartet of War Bonds. The winners, to the satisfaction of everyone with the possible exception of the unsuccessful aspirants, were six, yes six, young people from the Latin-American delegation. No one knew how the quartet became a sextet, but it did, and six War Bonds were eventually delivered by the generous hosts.

The Opening General Session itself was made memorable by the color of Mayor Fiorello H. LaGuardia in his address on Post-war Public Health, by the thoughtful Presidential Address of Dr. Felix J. Underwood, and by the presentation of the Sedgwick Memorial Medal to Brigadier General James Stevens Simmons, M.C. Dr. Underwood chose to speak on "Planning Today for Public Health Administration Tomorrow," and the paper is published in this issue.

For the third successive year, the Association's Annual Meeting was enriched by the presence of a number of representatives of Latin-American countries. Their attendance made possible by the Pan American Sanitary Bureau and the Office of the Coördinator of Inter-American Affairs, and a few coming as direct emissaries of their own governments, 68 of our friends to the south were present. Predominant among them were those with health education and laboratory interests. It will be recalled that administrative health officers were most numerous in the group that came to us in 1940, while last year engineers were in the majority. On the general program, delegates had the privilege of hearing Dr. Hernan Romero, Director, School of Public Health and Professor of Preventive Medicine and Hygiene, School of Medicine, University of Chile, Santiago; Dr. Felix Hurtado, Undersecretary of Health, Havana, Cuba; Dr.

Mario Pizzi of Chile; and Dr. G. H. de Paula Souza of Sao Paulo, Brazil. Through the good offices of Dr. Hugh S. Cumming and Dr. A. A. Moll, a special evening program was arranged where a number of papers on health problems and progress in several Central and South American countries were presented. While this was well attended, the real tribute to these visitors was paid by the Association on the occasion of the Second General Session. This was the only luncheon meeting of the Conference and it was attended by more than 500. Professor C.-E. A. Winslow, as spokesman, graciously and sincerely expressed the Association's "Welcome to Our Public Health Colleagues from the Americas." At the luncheon, too, forty year membership certificates were presented by Dr. Freeman to Dr. John F. Anderson, Mr. Wellington Donaldson, and Professor Irving Fisher, and the Health Officers of the communities on the National Health Honor Roll for 1942 were recognized.

The Health Education Center, conducted by the National Publicity Council for Health and Welfare Services for the Association, provided many educators-in-search-of-ideas with just what they were after. The Center was not a place for casual on-lookers. It was a spot where people stopped to look for a minute and hours later they were still there, wrapt, with portfolios piled high around them, and their own notebooks bulging. Mrs. Sallie Everson Bright and her colleagues turned the Center inside out to give the customers what they wanted.

And there was the Motion Picture Theatre with Mr. Thomas C. Stowell the impresario. And there were technical and a very limited number of scientific exhibits, crowded into small space necessarily, but still large in their implications of usefulness to public health workers.

The Association's exhibit of health

books of all publishers reappeared after an absence of several years. Conducted for the Association by the National Health Library, it presented nearly 500 recent books for the inspection of delegates. Featured was a "Five-Foot Shelf of Basic Books for Health Workers" compiled by the National Health Library Committee with the advice of the Secretaries of the Sections. Each Secretary was asked "If you were required to practise your specialty with only one book, what would you choose to work with?" In some instances one text was named; in others, any one book was declared inadequate and several were named as essential. Every Section Secretary contributed something to the Five-Foot Shelf, and the Library Committee made the final selections, after a period of firing the same question at all visitors to 1790 Broadway who would listen. No one reminded the committee of G. K. Chesterton's famous reply to the familiar question "If you were shipwrecked on a desert island, what book, etc." It was, you will remember, *Thomas' Guide to Practical Boat-Building*. The Shelf interested so many delegates that they carried away more than one thousand copies of a leaflet in which the titles of the books displayed thereon were printed. The few copies remaining will be mailed to those who request them.

What about a meeting next year? The question was asked many times with an inflection that indicated no doubt on the part of anyone that one should be held. But the Executive Board will decide that when it meets on January 28.

"WHERE DO WE STAND?"

This is the question prompted by any resident of the 135 communities which are represented in the 60 charts recently issued in a booklet by the Committee on Administrative Practice of the

American Public Health Association, under the title "Health Practice Indices." Proportion of tuberculosis cases reported in the minimal stage, births in hospitals, infants under nursing supervision, syphilis contacts examined, immunization of children under 2 years of age, pasteurized milk, satisfactory water supplies, budgets of health departments. These are samples of the practices which are graphically presented showing where each community stands in the array. The data were taken from the *Evaluation Schedules* presented for the National Health Honor Roll for the years 1941 and 1942. The names of communities are not shown, but any health officer represented can determine from his own data just where he stands in the country-wide array.

This is probably the first time that a widespread picture of detailed health practices in the United States has ever appeared in print. The pamphlet is intriguing. It is bound to create not only widespread interest, but should serve as a strong stimulus to do a better job. We are indebted to George T. Palmer, Dr.P.H., the Chairman of the Subcommittee on Manual and Appraisal of Local Health Work, and Mrs. Erminie Cross Lacey of the Commonwealth Fund, who was responsible for the tabulations and charting.

A COURSE OF STUDY IN HEALTH FOR BOSTON'S PAROCHIAL SCHOOLS

The Catholic Archdiocese of Boston has published a course of study in health for grades 1 to 8 which was prepared by the Boston Health Department and the schools of the Archdiocese. Among the members of the Committee on School Health Services are Charles F. Wilinsky, M.D., Deputy Commissioner of Health of Boston and Superintendent of Beth Israel Hospital; G. Lynde Gately, M.D., M.P.H., Commissioner of Health of Boston; and

Clair E. Turner, Dr.P.H., of the Department of Public Health of Massachusetts Institute of Technology.

The significance of this coöperative venture between the health department staff and the parochial schools is even greater than the excellent content of the volume, since it may well provide a pattern for health education in other areas.

WORTH ACQUIRING

The September, 1943, issue of *Channels*, publication of the National Publicity Council for Health and Welfare Services, Inc., 130 East 22nd St., New York, N. Y., for its article on "What's Ahead in Health Education" sub-titled "A Glimpse of Current and Coming Events and Materials"; also for the article "Organize the Story for Labor" which tells how to work through labor unions.

The first 1944 calendar we have seen, distributed with the "Compliments of the New York State Department of Health, Division of Public Health Education," Edward S. Godfrey, Jr., M.D., Commissioner, and Burt R. Rickards, Director. Safety—Yesterday and Today is its theme. Colorful, quaint, amusing, sometimes nostalgic, and altogether delightful, no one will relegate this to the waste-basket.

"Post-War Construction," a program adopted by the Board of Directors of the American Society of Civil Engineers, 33 West 39th St., New York, N. Y., which includes housing. Brief and concise and interesting because it presents a program of immediate planning, starting from where we are and not geared to the brave new world our national advertisers have dreamed up for us.

"Selection and Training of Volunteers in Child Care," published by the Children's Bureau, Washington, D. C. A partial solution of the problem of personnel shortages in nursing, teaching, social work, and health education.

The October 4 issue of *Life* for its ten page discussion of the essentials of nutrition and what must be done to achieve a balanced diet for the whole world.

"Standards for Neighborhood Recreation Areas and Facilities," National Recreation Association, 315 Fourth

Avenue, New York, N. Y. You can check how your community stands with relation to the standard space requirement of one acre of neighborhood playground space for each 800 of the population, a community recreation building for at least every 20,000 of the population and other things.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Mind, Medicine and Man—By Gregory Zilboorg. New York: Harcourt Brace, 1943. 344 pp. Price, \$3.50.

Mind, Medicine, and Man, is an original and provocative book. It is original in the sense that it is laden with the author's personal and unique interpretations and pleas. It is provocative in the sense that many of the author's interpretations elicit numerous questions and strong dissent.

The most satisfactory chapters of the book are those entitled "Instincts and Their Manifestations," "Normal Neuroses and Personality," "Certain Aspects of Mental Illness," and "Theories and Practice." In these chapters the author restates, frequently very aptly, the basic theories and principles of psychoanalytic psychiatry. Here, with profit, the author works over well cultivated ground. The preceding chapter "On Certain Misconceptions," and those that follow "Civilization and the Social Sciences," "Varieties of Human Aggression," "Crime and Judgment," and "Psyche, Soul, and Religion" constitute the author's "dicta" on a variety of subjects, principally on sociology, anthropology, criminology and law, and religion.

It is not possible in the space of a review to elaborate the questions and dissents which these portions of the book evoke. A few general comments must suffice. Dr. Zilboorg is evidently a man of wide knowledge, but his erudition frequently encumbers his exposition. He is at times guilty of overstatement, and of strong affirmation, where only tentative suggestion is war-

ranted. He does poor justice to Jung and none at all to Adolf Meyer. He is at times careless in his statements on medical history.

Nonetheless this work can be read with profit, precisely perhaps because it is so provocative.

IAGO GALDSTON

Rehabilitation of the Tuberculous—By H. A. Pattison, M.D., F.A.C.P. Livingston, N. Y.: Livingston Press, 1942. 186 pp. Price, \$2.50.

Public health workers as a group are not leaders in the field of rehabilitation. This volume is significant partly because the author, after a varied background of public health experience, has published a review of what we know about rehabilitating the tuberculous, and it can be read with profit by anybody. The volume includes a review of the problems underlying rehabilitation and, in Part 2, an account of in-sanatorium work, together with accounts of the programs in 18 rehabilitation centers in the United States and abroad.

As a point of departure for post-war planning, this book can be widely useful. It might open the eyes of other readers as it has opened the eyes of this reviewer. REGINALD M. ATWATER

Essays in Biology—In Honor of Herbert M. Evans. Los Angeles: University of California Press, 1943. 687 pp. Price, \$10.00.

This beautifully printed and elegantly bound volume was prepared in honor of Herbert McLean Evans, Professor of Anatomy at the University of California, by a group of his friends

on his 60th birthday. It contains 48 articles on various biological subjects ranging from the historical and philosophical such as "The Impact of the Introduction of Iron on Medical and Religious Thought" by Alvarez, and "Impotency as a Result of Witchcraft" by Sigerist, through diverse phases of endocrinology such as "Pituitary Gonadotrophins" by Fraenkel-Conrat, Choh Hao Li and M. E. Simpson, and "Ovum, Cycle and Menstruation" by Zondek, to others on Physiology, Embryology, Nutrition, and on Pathology, the latter including titles such as "Pulmonic Interstitial Emphysema and Its Sequelae" by C. C. Macklin and M. T. Macklin, and "Observations on the Pathogenesis of Undulant Fever" by K. F. Meyer. A detailed analysis or even a complete list of all of these essays is not possible here because the fields covered are too diverse for review by one individual. The list of authors, however, alone carries authority and prestige which make this collection of essays a highly desirable source book for research workers and a monumental tribute to Professor Evans and his very fruitful and stimulating life work which, it is earnestly hoped, may continue for many years.

In the forepart of the volume are a fine sepia portrait of Dr. Evans, a dedication, and an explanatory note with acknowledgements from the Publication Committee consisting of Samuel T. Farquhar, Chauncy D. Leake, William R. Lyons, and Miriam E. Simpson, Chairman. These are followed by a biographical sketch, a complete bibliography of Dr. Evans (containing nearly 400 citations) from 1904 to 1942, and a table of contents.

MARTIN FROBISHER, JR.

Atlas of Human Anatomy—By F. Frohse, M. Brodel, and L. Schlossberg. (New ed.) New York: Barnes

& Noble, 1942. 90 pp. Price, \$2.25.

This book has been known since its first edition for the excellent color reproduction of the celebrated Frohse-Brodel anatomical charts. Public health workers who have sometimes only a thin veneer of knowledge in human biology will profit by and also enjoy the excellent introduction and explanatory text by Jesse F. Williams. The new edition shows for the first time a series of illustrations on the endocrine glands. As the microscopic illustrations are not in color, they do very little in helping to understand the function of the glands, and the explanatory text of this chapter by Charles F. Geschickter is too technical for the non-medical reader. Nevertheless, the book is still the best available pocket-size atlas on human anatomy.

BRUNO GEBHARD

Public Works Engineers Yearbook—1943—Chicago: American Public Works Association, 1943. 333 pp. Price, \$3.75.

This publication includes the year's affairs of the association and the proceedings of the 1942 Public Works Congress. Important and authoritative information on current technics and practices, reflecting the impact of war induced conditions upon essential operations in the public service field, is given in the proceedings. Employee relations, financial programming, substitutes and salvage, traffic, operation of sewerage systems and developments in refuse collection and disposal are among the topics covered.

ARTHUR P. MILLER

Laboratory Manual for Chemical and Bacterial Analysis of Water and Sewage—By Frank R. Theroux, M.C.E., Edward F. Eldridge, M.S., W. LeRoy Mallmann, Ph.D. New York: McGraw-Hill, 1943. 274 pp. Price, \$3.00.

This manual now appears in an enlarged third edition. In format it resembles the previous editions in that procedures are listed step by step. An entirely new section dealing with the testing of boiler waters has been added for the first time. Eight new testing procedures are suggested, descriptions are given for the preparation of about 20 new reagents, the general discussion of chemistry and related topics has been expanded, and many revisions have been made in the bacteriological section as a result of recent developments in this field. In addition, problems with answers are included in the general chemical discussion.

There is no doubt that the book in its present edition will prove to be as popular with operators, students, and others as have past editions. To this reviewer, however, it seems that recent research has given sufficient emphasis to the need for proper dilution waters in some of our biochemical oxygen demand studies on sewage and trade wastes to warrant a discussion of these waters and of procedures for their preparation.

C. P. STRAUB

Health Practice Indices—Prepared by the Subcommittee on Manual and Appraisal of Local Health Work for the Committee on Administrative Practice of the American Public Health Association. New York, 1943. 73 pp.

In *Health Practice Indices*, data submitted from the evaluation schedules for the National Honor Roll have been compiled. These make possible a study of the accomplishments in certain services of health departments. Analysis of these data for an understanding of procedures, and the assembly of this material in a form available for study by the various communities, seems to be a good idea. Although in evaluating administrative practice it is desirable to know the procedures being rendered and to compare results for

various areas, such comparisons are extremely difficult. It is well known that the comparison of crude death rates is subject to error. How much more difficult is the comparison of health department services when the actual need for health services varies in communities over the country according to composition of the population and the availability of medical services! Another factor to be considered is the need for adaptation of procedures according to local problems.

In *Health Practice Indices*, only communities are included which, due to interest or perhaps clerical assistance, submitted schedules, and thus the results are probably not representative of health department services for the country. Since the data have not been checked for consistency of interpretation, without doubt some of the variation—especially the extreme values—may be due to errors in the data submitted. One hundred per cent success is hard to attain in any program!

These are some of the factors to be considered in reading and using *Health Practice Indices*. This report should serve to stimulate discussion of the practicability and need for measures of health service.

R. H. HUTCHESON

A Guide to Practical Nutrition—Sponsored by the Committee on Nutrition and Deficiency Diseases of The Philadelphia County Medical Society. Edited by Michael G. Wohl, M.D., and John H. Willard, M.D. The Philadelphia County Medical Society, 1943. 98 pp.

This manual is a paper bound reprint of a series of short articles on various aspects of nutrition which appeared in *Philadelphia Medicine* in 1941–1942. The author of each of the thirteen subjects covered is a clinician, investigator, or dietitian on the staff of a local hospital or medical school.

The *Guide to Nutrition*, according to

the editors, is to be considered as part of a program of public health education and not a complete coverage of the field of nutrition, and is presented to the medical profession in order to increase the practising physician's interest in the new knowledge of nutrition.

The committee and authors are to be commended for their efforts to stimulate interest in this field. However, since the articles are written in a style and manner more suitable for journal presentation, one suspects that the purpose for which they were intended has already been accomplished by the original publications. There has been so much written recently on practical nutrition, both in a comprehensive and a brief form, that unless a new book possesses some unusual merits it is apt to attract little attention. *A Guide to Practical Nutrition* is not an exceptional book. The quality of the articles varies considerably; some subjects are presented concisely, clearly, and adequately for the purpose intended, while other sections suffer from lack of judgment in selection and interpretation of material or in clarity of presentation. The coverage is insufficient to recommend it as a guide to those interested in a brief but complete summary of the subject. However, the book will be of interest to those who wish to read short summaries of selected topics.

OTTO A. BESSEY

General Bacteriology—By D. B. Swingle. New York: Van Nostrand, 1943. 313 pp. Price, \$3.00.

This is a reprinting of a beginner's text originally published in 1940. The author considers the usual method of presenting bacteriological knowledge to be too frequently an elaboration of medical bacteriology, and has endeavored to present it as a distinct science with orderly arrangement, principles and applications comparable to those found in other sciences. Rela-

tionships to other branches of biological science, physics, and chemistry are stressed with the object of giving beginners a broad base on which to build advanced studies in the field.

Fundamentals of bacterial morphology, classification, and metabolism are presented first, followed by a brief discussion of yeasts and molds, and then by a series of chapters on bacteria of the soil, water, air, milk, industry, etc. Finally 40 pages are devoted to infection, immunity, and pathogenic organisms.

The text is illustrated with many photographs and drawings, most of the latter giving an impression of size and detail much beyond anything actually seen under the microscope.

EDMUND K. KLINE

Public Health Nursing in Obstetrics, Part IV, Mothers' and Fathers' Classes—New York: Maternity Center Association. 108 pp. Price, \$1.00.

Maternity Center Association's quarter century of experience in conducting Mothers' Classes, makes this book an attractive and a valuable source of information for any who want to start this kind of educational maternal health work. A good case is made for the need for more men's and women's classes. Ways to organize and conduct classes for both men and women are listed. Among the subjects considered are the instructor, sponsorship, approach, classroom arrangement, and teaching aids. If followed, the suggestions listed will protect the would-be educator from a number of errors. The unit outlines will serve as a check list for those who have been conducting classes and wish to compare course content.

The seven instruction units on Teaching Suggestions and Outlines for Mothers' Classes cover 75 of the book's 108 pages. Each outline has an introductory statement. Those which pre-

ceed the first two units are narrative in form and exceptionally well done. There is some unevenness in the quality of the outlines. The first two are quite technical and consist mostly of the basic material a teacher should have mastered for interpretation. Some instructors would not find that their class groups could benefit by such detailed discussions. The remaining outlines are both more general and more practical. Two features, the Bibliography and Teaching Aids, are more than ordinarily complete for such a volume, and the illustrations of the charts produced by, and available from Maternity Center are reproduced exceptionally well.

Though the Teaching Outlines for Fathers' Classes are rather disappointing in their brevity after the complete outlines for mothers, nevertheless, this book will be well received by those who are teaching, or those who plan to teach classes for mothers and fathers.

DAVID B. TREAT

Shipboard Medical Practice—By W. L. Wheeler, Jr. New York: Cornell Maritime Press, 1943. 106 pp. Price, \$1.00.

Shipboard Medical Practice is a handbook of 106 pages on emergency medical aid at sea. The advice and instructions given are based on using the materials and resources ordinarily available to seamen on ships and in lifeboats. The book is plainly written in a clear and concise language for seamen with little or no medical knowledge. Information on artificial respiration, shock, wounds, exposure, nutrition, and general care of lifeboat survivors is included. The supplies furnished in "Lifeboat and Life Raft First Aid Kits" are listed. The use of sulfathiazole in several different forms and for a number of different conditions is described.

A number of preventable diseases are discussed as to prevention, symptoms,

and treatment. While the entire discussion of specific diseases is quite brief, the preventive phases particularly, appear to the reviewer to be somewhat inadequately covered. The chapter on sanitation is definitely too brief, and is not entirely up to date.

While this little book will undoubtedly serve as a helpful handbook, as intended, a number of other more complete books on First Aid and on the prevention, symptoms, and treatment of specific diseases would seem to be desirable for seamen who may be called upon to render emergency medical aid on shipboard.

There is a closing chapter on the proper way to send emergency radio messages to medical officers of the U. S. Public Health Service, in order to be understood and thus save time, suffering, and perhaps life by receiving prompt advice.

ALFRED H. FLETCHER

Plumbing Practice and Design—Volume 2—By Svend Plum. New York: Wiley, 1943. 329 pp. Price, \$4.50.

This companion volume to the author's first text on plumbing is an attempt, as previously stated, to consolidate the scattered data on plumbing, and to present these data in uniform terminology and in a manner usable for solving the many problems occurring in the design of plumbing systems. Practical information is presented for use in the layout and design of water supply and heating systems, sewerage and drainage systems, and gas piping systems. There is a chapter on definitions of physical and chemical terms, one on codes and regulations, and one on architectural practice.

This text should do much to eliminate some of the mystery which shrouds present-day design of plumbing systems, as the designs presented are based on sound engineering principles.

C. P. STRAUB

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

In a Nutshell—For the past ten years the peak of the polio epidemic has usually occurred in the middle week of September, the average number of cases reported during the first 36 weeks of the year being 3,796. For 1943 the number reported (up to September 11) was 6,792. States with the highest incidence were: Connecticut, Illinois, Kansas, Oklahoma, Texas, Colorado, Arizona, Utah, and California.

ANON. Prevalence of Poliomyelitis. Pub. Health Rep. 58, 38:1412 (Sept. 17), 1943.

Reassuring Report — Highlights from a health accounting of the services: disease incidence lower in '42 than previous year and continuing good in '43; Army's V.D. at all-time low; meningitis epidemic fell off quickly; vaccinations proved effective against the diseases for which they are intended; dysenteries constitute chief threat in areas of high incidence, but malaria is the leading enemy. There are adequate supplies of essential drugs.

ANON. Health of the Armed Services. J.A.M.A. 123, 8:487 (Oct. 23), 1943.

Thoughts on an Inferential Science—This dissertation on wrong-way epidemiology and opinionated epidemiologists is not easy reading but it will make you into a more humble person if you read it. Humble and more soundly functioning, too.

AYCOCK, W. L. and RUSSELL, F. F. The Functions of Hypotheses in Epidemiology. Am. J. M. Sc. 206, 3:399 (Sept.), 1943.

Too Bad!—Calcium is probably one of the prevalent deficiencies in our diet. This researcher went to great pains to see if a galvanic current could be used

to measure the adequacy of calcium nutrition, but he reached the conclusion that he had educed no evidence that the response to galvanic stimulation was a good test for mild deficiency states.

BEEBE, G. W. Medical Evaluation of Nutritional Status. Milbank Quart. 21, 4:311 (Oct.), 1943.

Typhoid Vaccine at Work—Evidence is presented which indicates that the triple typhoid vaccine now used by the army is considerably the superior of the T A B product used during World War I.

CALLENDAR, G. R. and LUIPFOLD, G. F. The Effectiveness of Typhoid Vaccine Prepared by the U. S. Army. J.A.M.A. 123, 6:319 (Oct. 9), 1943.

Home Care of the Sick—How do people behave when they are sick? Some go to the doctor and more than half of those who do have medicine given or prescribed for them. Some ask the druggist what to take, but more think that Peruna, *et al.*, will do the trick so they demand what they want. As one might expect, men and women, well-to-do and poor, smalltown slickers, and city people all behave variously in these matters.

COLLINS, S. D. The Frequency of Doctor's Prescriptions and of Laboratory and Related Services in the Treatment of Illness. Milbank Quart. 21, 4:344 (Oct.), 1943.

Timely Notes on the Sniffles—Sinusitis, otis media, and the other sequelae of the common cold are reduced in number and severity if nose and throat are sprayed with a sulfonamide drug, with or without added medicaments, say the nine authors of the two papers named.

DOLOWITZ, D. A., *et al.* The Prevention of Ear and Nasal Sinus Complications of the Common Cold, (and) TURNBULL, F. M. *et al.* Sinusitis and Infections Secondary to the Common Cold. J.A.M.A. 123, 9:534 (Oct. 30), 1943.

Report on the First Ten Thousand—Adding up the minor disadvantages and major advantages of caudal analgesia, the authors point out again the great need for a high degree of obstetric competence on the part of physicians who propose to utilize the method. In such hands fetal mortality should be considerably decreased.

HINGSON, R. A., and EDWARDS, W. B. Continuous Caudal Analgesia. J.A.M.A. 123, 9:538 (Oct. 30), 1943.

What Next? —Sulfadiazine by mouth in small doses is an effective method of curbing epidemics of meningitis among large bodies of troops.

KUHNS, D. M., *et al.* The Prophylactic Value of Sulfadiazine. J.A.M.A. 123, 6:335 (Oct. 9), 1943.

Send Not To Ask For Whom the Bell Tolls—This is the story as I remember it: on a stifling July morning the chicken meat to make a supper salad for a large institution was shredded from the carcasses by hand, then salad dressing was thoroughly mixed into the meat, also by hand (bare), then the salad stood until supper time. One of the kitchen help who did the mixing had returned to work a day or two earlier after a 4 day bout with diarrhea. Just to complicate the picture, the cooked fowl stood for a day before shredding, the kitchen was far from clean, cockroaches and flies were plentiful. Instead of retailing to you the morbid statistics of the epidemic, these questions are asked: are there institutions like this one in your bailiwick, and what are you doing about them?

LUMSDEN, L. L., *et al.* A Study of an Outbreak of Food Poisoning in Galveston,

Texas. Pub. Health Rep. 58, 41:1497 (Oct. 8), 1943.

A Challenge to Unintelligent Complacency —Noise, say these authors, such as now attends most human activities is injurious. This is not a matter of speculation. Further, relief from noise is procurable, so patient endurance of excessive man-made noises is no longer a virtue. To this every reader of the article will say: Amen.

MCCORD, C. P., and GOODELL, J. D. The Abatement of Noise. J.A.M.A. 123, 8:476 (Oct. 23), 1943.

When Infected Hairs Become Fluorescent—This story of the unusual ringworm epidemic in certain New York schools, and the effective methods employed to end it should be clipped and stored away safely in your files of scientific material. Such an outbreak "shouldn't happen to you" but it may.

MITCHELL, H. H., *et al.* An Epidemic of Ringworm of the Scalp. Pub. Health Nurs. 35, 10:564 (Oct), 1943.

Early Treatment for Rabies—Conclusion-jumpers had better keep both feet on the ground but, experimentally, wounds inoculated with fixed rabies virus were as effectively treated when irrigated with green soap solution as when they were cauterized with fuming nitric acid. Sulfanilamide did no good whatever, and iodine "also ran."

SHAUGHNESSY, H. J. and ZICHIS, J. Prevention of Experimental Rabies. J.A.M.A. 123, 9:528 (Oct. 30), 1943.

Up to the War Years the Record Was Fine—From 1900 to 1941 the tuberculosis death rate shows an almost continuous, year-by-year decline (except for 1918). And this has occurred despite the ageing of our population and the late inclusion of certain states (with higher TB rates) to the registration

area. The decrease for females was greater than for males, and the reduction has been experienced by other groups as well as whites. A curve of tuberculosis mortality relative to total

mortality is suggested as an indicator of future courses of the disease.

YERUSHALMY, J., *et al.* Tuberculosis Mortality in the United States. Pub. Health Rep. 58, 40:1457 (Oct. 1), 1943.

ASSOCIATION NEWS

JOHN J. SIPPY, M.D., PRESIDENT-ELECT

Dr. Sippy, a native of Madison County, Ill., is a graduate in 1899 of the St. Louis College of Physicians and Surgeons. He practised medicine for several years and was successively County Health Officer in Kansas and Epidemiologist to the Kansas State Department of Public Health. For three

1923, he has been District Health Officer of the San Joaquin Local Health District, with headquarters in Stockton, Calif. Since 1934, he has been Associate Clinical Professor of Public Health and Preventive Medicine at the School of Medicine, Stanford University.

Since he has been in the West, Dr. Sippy has served as Secretary of the Montana Public Health Association and, in 1929, he was President of the Northern California Public Health Association. The Western Branch, American Public Health Association, honored him in 1941 with the Presidency. Twice he has been President of his County Medical Association. He was President of the League of California Cities in 1927. He has been a member of the White House Conference on Child Health and Protection and, for ten years, held a Reserve Commission as Passed Assistant Surgeon in the U. S. Public Health Service. Dr. Sippy joined the Association in 1919 and was elected to Fellowship in the Health Officers Section in 1930. Throughout the western states, Dr. Sippy has had a wide influence in administrative practice, where he is generally regarded as the Dean of local health officers.

JOHN J. SIPPY, M.D.

years he served as Executive Secretary of the Kansas Tuberculosis Association and as lecturer on communicable disease at the University of Kansas School of Medicine. In 1919, Dr. Sippy moved to Montana, where for three years he was Epidemiologist and then Director of Child Welfare in the Montana State Department of Health. Since

FORTY-YEAR MEMBERSHIP RECOGNITION

At the 2nd General Session of the New York Annual Meeting and Wartime Conference, Dr. Allen W. Freeman, President of the Association, presented three forty-year membership certificates to the following persons: John F. Anderson, M.D. of New Brunswick, N. J., President of the American Public Health Association in 1916; Wellington

Left to right—Allen W. Freeman, M.D., Outgoing President of the Association, making presentation; John F. Anderson, M.D.; Wellington Donaldson; and Irving Fisher, Ph.D., LL.D. Seated is C.-E. A. Winslow, Dr.P.H., Chairman of the Sedgwick Memorial Medal Committee.

Donaldson of the Department of Public Works of New York City; Irving Fisher, Ph.D., LL.D., of Yale University, New Haven, Conn.

Dr. Freeman pointed out that this custom was begun 8 years ago, since which time twenty-three awards have been made to members who joined the Association as far back as 1878. The senior name of those holding extended memberships is that of Dr. John Harvey Kellogg of Battle Creek, Mich., who joined the Association in 1878. Dr. Kellogg thus completes 65 years of membership in the Association.

NEW A.P.H.A. SECTION ON DENTAL HEALTH

The Governing Council at the 72nd Annual Meeting of the Association recently held in New York City created

a Section on Dental Health, making twelve sections in all for the American Public Health Association. This is an outgrowth of the Oral Health Group started in 1937 in an attempt to explore this field on an informal basis.

The new Officers of the Section on Dental Health are as follows:

Chairman: Kenneth A. Easlick, D.D.S., School of Public Health, University of Michigan, Ann Arbor, Mich.

Vice-Chairman: J. M. Wisan, D.D.S., State Department of Health, Trenton, N. J.

Secretary: W. J. Pelton, D.D.S., M.S.P.H., U. S. Public Health Service, Washington 14, D. C.

Section Council:

1948—C. R. Taylor, D.D.S., M.S.P.H., Michigan State Health Department, Lansing, Mich.

1947—Lester A. Gerlach, D.D.S., City Health Department, Milwaukee, Wis.

1946—George A. Nevitt, D.D.S., M.S.P.H.,

Sub-Treasury Building, 15 Pine Street, New York, N. Y.

1945—Richard C. Leonard, D.D.S., M.S.P.H.,
State Department of Health, Baltimore, Md.

1944—Allen O. Gruebbel, D.D.S., M.P.H.,
State Board of Health, Jefferson City, Mo.

This recognition of the expanding place of public health dentistry has been accomplished with full realization that public health dentistry stands to gain from the inter-Sectional relationships afforded by the American Public Health Association and especially with the interests represented in the School Health Section, the Public Health Education Section, the Food and Nutrition Section, and the Epidemiology Section. It is anticipated that, by means of joint sessions and other coöperative planning, there may be achieved a better orientation of public health dentistry with the other specialties of the public health movement.

The Association office is prepared to receive applications for membership in the new Section on Dental Health, either from persons already identified with other Sections of the American Public Health Association or from new members. Address the Association, 1790 Broadway, New York 19, New York.

PROGRESS IN THE MERIT SYSTEM UNIT

During the Annual Meeting of the Association, the Subcommittee on Merit Systems of the Professional Education Committee reported on progress in supplying examination materials to state merit system-councils. Dr. George H.

Ramsey indicated that the public health nursing materials have been used in 10 states for 34 examinations. There is now a substantial demand from other fields in public health and the Unit is prepared to provide examination questions for medical health officers, laboratory workers, and in the field of environmental sanitation. Subject consultants appointed to assist the Unit in the two latter fields are: Dr. Edmund K. Kline, Secretary of the A.P.H.A. Laboratory Section, and Alfred Fletcher of Johns Hopkins University with the assistance of Walter Mangold of the University of California. Dr. Lillian Dick Long continues as psychometrician. Assistance in securing suitable questions for these fields is being sought from groups outside of the New York area, and reviewers—especially in the field of public health nursing—have been chosen from all over the United States.

During the Annual Meeting the staff of the Merit System Unit held consultation hours and a report of progress in the field of public health nursing was made by the Subject Consultant, Dorothy Deming, to the State Supervising Nurses and the Public Health Nursing Section. A round-table meeting, open to all interested in merit system problems, was held on October 14. Approximately 35 persons attended including representatives of the U. S. Public Health Service, Children's Bureau, and State Merit System Councils.

NEW FELLOWS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION ELECTED AT THE WARTIME PUBLIC HEALTH CONFERENCE

Health Officers Section

Franklyn B. Amos, M.D., M.S.P.H.

Daniel Bergsma, M.D.

Edward R. Krumbiegel, M.D.

Carl N. Neupert, M.D., M.S.P.H.

William M. Smith, M.D., M.P.H.

Mary Steichen, M.D., M.S.P.H.

Wilmier M. Talbert, M.D., M.S.P.H.

Alexander Witkow, M.D., M.P.H.

Laboratory Section

G. D. W. Cameron, M.D., D.P.H.

Orren D. Chapman, M.D.

Ward H. Cook, M.D.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Neale M. Atkins, M.D., Graves County Board of Health, Mayfield, Ky., Health Officer
 Vernon A. Ayer, M.D., M.S.P.H., 2309 7th Ave., New York, N. Y., Asst. Health Officer, New York City Health Dept.
 Willard C. Baker, M.D., 5673 Main St., Williamsville 21, N. Y., Health Officer, Consolidated Health District
 Raymond F. Barnes, M.D., 22 North Elm Ave., Webster Groves, Mo., Assoc. Director, Medical Health Service, Mid-Western Area, American Red Cross
 F. Wellington Brecker, M.D., 27 Wells Ave., East Hartford, Conn., Health Officer
 Dr. Agnes L. Brown, Muhlenberg County Health Dept., Greenville, Ky., Health Officer
 Cleaveland Floyd, M.D., 246 Marlborough St., Boston, Mass., Chief Medical Examiner, Tuberculosis Division, Boston Health Dept.
 Leonhard F. Fuld, Ph.D., Medical Center, Jersey City 4, N. J., Health Director
 Louis E. Harmon, M.D., 2340 Madison Ave., Baltimore, Md., Supervisor, Venereal Disease Clinic, City Health Dept.
 William H. Kober, M.D., Box F, Lima, N. Y., Health Officer
 Bernard McD. Krug, M.D., County Commissioner of Health, Cortland, N. Y.
 Eaton G. Lindner, M.D., 1117 Lake Wier Ave., Ocala, Fla., Director, City-County Health Dept.
 S. Easton McManis, M.D., 407 E. Main St., Endicott, N. Y., Health Officer, Village of Endicott
 Verlin E. Miles, M.D., 1604 N. Garfield St., Arlington, Va., Asst. Health Officer, Arlington County Health Dept.
 Fridgeir Olason, M.D., M.P.H., Harvard School of Public Health, Boston, Mass., Student
 Dorothy A. Oppenheim, M.D., 769 Onderdonk Ave., Brooklyn 27, N. Y., Asst. Health Officer, New York City Dept. of Health
 A. R. Perry, M.D., M.P.H., Health Dept., Natchez, Miss., Director, Adams County Health Dept.

Robert W. Ripley, M.D., Court House, Pasco Wash., Asst. Health Officer, Benton-Franklin District Health Office
 Edward S. Rogers, Bureau of Health, City Hall, Trenton, N. J., Chief Sanitary Inspector
 Major Sidney N. Tucker, M.C., Letterman General Hospital, Presidio of San Francisco, Calif., Chief of Communicable Disease Section
 Clark H. Yeager, Dr.P.H., 13 Midvale Rd., Baltimore, Md., Chief of Medical Section, Health and Sanitation Div., Office of Coordinator of Inter-American Affairs

Laboratory Section

Lt. Col. Joseph D. Aronson, M.C., Station Hospital, Fort Belvoir, Va., Laboratory Officer, U. S. Army
 Leitha D. Bunch, M.A., 635 North Fairview, Lansing 12, Mich., Biochemist, State Dept. of Health
 Benjamin W. Carey, M.D., 142 Second Ave., Westwood, N. J., Asst. Director, Lederle Laboratories, Inc.
 Philip L. Carpenter, Ph.D., Dept of Bacteriology, Rhode Island State College, Kingston, R. I., Asst. Professor of Bacteriology
 Lt. Arthur J. Cohane, Sn.C., 273 Station Hospital, Camp Butner, N. C., Sanitary Officer, U. S. Army
 Carl E. Duffy, Ph.D., 106 S. Lansdowne Ave., Lansdowne, Pa., Bacteriologist, Sharp & Dohme, Inc.
 Armand Frappier, M.D., 2900 Mt. Royal Blvd., Montreal, Que., Canada, Director, Institute of Microbiology and Hygiene, Univ. of Montreal
 Helen H. Gillette, 519 State House, Boston, Mass., Senior Bacteriologist, State Dept. of Public Health
 Cpl. Louis J. Grosso, SCU 1941, P. O. Box 651, Tracy, Calif., Laboratory Technician and Water Analyst, U. S. Army
 S. David Kramer, Ph.D., State Dept. of Health Labs., Div. of Virology, Lansing 4,

- Mich., Assoc. Director, Bureau of Laboratories

Health

RESOLUTIONS

The following Resolutions were unanimously adopted by the Association at the Seventy-second Annual Meeting in New York, N. Y., October 12-14, 1943.

1. APPRECIATION

TO DR. STEBBINS AND THE LOCAL COMMITTEE

RESOLVED that the American Public Health Association express its grateful appreciation to the New York Local Committee and to the agencies and individuals represented thereon.

RESOLVED that the thanks of the officers and members be extended to Dr. E. L. Stebbins, Health Commissioner of New York and General Chairman of the Local Committee, and to the chairmen and members of the several subcommittees whose services have contributed so markedly to the success of the Wartime Conference and Seventy-second Annual Business Meeting.

TO THE NEW YORK CITY AND NEW YORK STATE HEALTH DEPARTMENTS AND HEALTH COMMISSIONERS OF NEW JERSEY AND CONNECTICUT

RESOLVED that the American Public Health Association express its thanks to the New York City Health Department and the New York State Health Department, to the Commissioner of Health of New Jersey, and to the Commissioner of Health of Connecticut for their valuable assistance in the conduct of this Annual Meeting.

TO THE NEW YORK CONVENTION AND VISITORS BUREAU AND TO THE HOTEL PENNSYLVANIA

RESOLVED that the American Public Health Association express its thanks to the New York Convention and Visitors Bureau and to the Hotel Pennsylvania for their coöperation in making such excellent facilities available for the Seventy-second Annual Business Meeting.

TO COÖPERATING AGENCIES

RESOLVED that the American Public Health Association express its grateful appreciation to the Public Health Association of New York City, to the National Health Council agencies, to the National Health Library, and to the National Publicity Council for their excellent assistance in the conduct of this meeting.

TO THE PRESS AND RADIO

RESOLVED that the American Public Health Association acknowledge its indebtedness to the press and radio, national, state, and local for its service in connection with the Wartime Conference.

TO EXHIBITORS

RESOLVED that the American Public Health Association express its grateful appreciation to its friends and coöperators who have presented at its Wartime Conference and 72nd Annual Business Meeting the excellent exhibits which are of such great interest and value.

2. IN MEMORIAM

RESOLVED that it is with a sense of irreparable loss that the American Public Health Association records, since its last Annual Meeting, the death of 48 Fellows and members, the names of whom constitute a part of this resolution.

J. S. Abbott, Washington, D. C., Elected Member 1925, Fellow 1929.

 William J. Ryan, M.D., Pomona, N. Y., Elected Member 1934.
 Fred C. Spalding, Valley City, N. D., Elected Member 1939.
 J. F. X. Stack, M. D., Hoboken, N. J., Elected Member 1923.
 William Thau, M.D., Boston, Mass., Elected Member 1937.
 Arthur H. Thomas, Philadelphia, Pa., Elected Member 1913.
 Leslie T. Webster, M.D., New York, N. Y., Elected Member 1935, Fellow 1940.
 Robert S. Weston, Boston, Mass., Elected Member 1896, Charter Fellow 1922.
 LeRoy A. Wilkes, M.D., Trenton, N. J., Elected Member 1919.
 Frank A. Williams, M.D., Lake Providence, La., Elected Member 1936.

3. DISTRIBUTION OF PUBLIC HEALTH NURSING PERSONNEL

WHEREAS, the nursing division of the Procurement and Assignment Service of the War Manpower Commission has developed principles and objectives which seem desirable for the proper utilization of public health nursing personnel, and

WHEREAS, the success of the application of these principles depends upon the understanding and support of health agencies and of the public, therefore be it

RESOLVED that the American Public Health Association recommend that health departments and public health nursing agencies take an active part in assisting local nursing committees of Procurement and Assignment to obtain equitable distribution of nursing personnel in ways best suited to local situations and to gain public understanding and support of this distribution.

4. PERSONNEL POLICY DURING THE EMERGENCY

WHEREAS, it is essential that practical action be taken by state and local health departments to meet the personnel shortage during the war emergency, and

WHEREAS, the American Public Health Association Committee on Professional Education has prepared a statement on this problem

which was published in Volume 33, No. 7, July, 1943 issue of the *American Journal of Public Health* which suggests a solution of the problem without jeopardizing future qualifications of permanent public health personnel, therefore be it

RESOLVED that the American Public Health Association recommend this published statement as a guide to personnel policy during the war emergency.

5. LABORATORY SUPPLIES AND EQUIPMENT

WHEREAS, state and all other public health laboratories are encountering increasingly serious difficulties in the procurement of supplies and equipment essential to their effective functioning, without which the provision of adequate safeguards for the public health is impossible; and recognizing that the current health hazards are increasing because of the intensity and extent of the war effort, therefore be it

RESOLVED that the American Public Health Association request the proper authority to designate The United States Public Health Service as a claimant agency, subject to the organization's willingness so to serve, with due recognition and authority under War Production Board regulations, to insure that supplies and equipment essential for laboratory purposes be made available to the extent necessary to overcome these difficulties.

6. DIVISION OF INDUSTRIAL HYGIENE IN THE DEPARTMENT OF LABOR

WHEREAS, it appears that there has been introduced into Congress a Bill (H.R. 2800) which proposes an extension of the activi-

ties of the Department of Labor by creating therein a division of industrial hygiene, and WHEREAS, it further appears that the creation of such a division of industrial hygiene in the Department of Labor would duplicate the activities already provided for in the U. S. Public Health Service for this purpose and furthermore would tend to interfere in similar services carried out in the various states and the health departments now therefore be it

RESOLVED that the American Public Health Association hereby declare itself as opposed to such legislation, and be it further

RESOLVED that a copy of this resolution be forwarded to the committees of Congress that have this matter before them.

7. PAN AMERICAN HEALTH DAY

WHEREAS, the second of December has been declared Pan American Health Day by official proclamation of the Governments of all the American Republics, and

WHEREAS, this Inter-American celebration has assumed increasing importance in the different countries of the Western Hemisphere, therefore, be it

RESOLVED that the Executive Board urges all members of the American Public Health Association to lend their fullest coöperation in order that this day may be endowed with even greater significance from the standpoint of Hemispheric solidarity and the promotion of health, and especially urge such members as occupy responsible positions either in health departments or scientific institutions to place themselves in touch with the Pan American Sanitary Bureau so that they may coöperate in an effective and practical manner in this enterprise.

DECEASED MEMBERS

Courtenay Dinwiddie, New York, N. Y., elected Member 1916, Charter Fellow 1922, Maternal and Child Health Section.

J. Leake, M.D., Portsmouth, Va., Elected Member 1933, Health Officers Section.

Thomas A. Storey, M.D. Stanford University,

Calif., Elected Member 1912, Charter Fellow 1922, Life Member 1932, Maternal and Child Health Section.

Hassow Von Wedel, M.D., New Rochelle, N. Y., Elected Member 1915, Charter fellow 1922, Laboratory Section.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

Physician: public health pediatrics. To assist director of maternal and child health in large California county health department. Major duties, conducting of infant and preschool health conferences and school examination. Beginning salary \$350 and travel. Training and experience in pediatrics or public health or both. Immediately available. Address William C. Buss, M.D., Kern County Health Department, Bakersfield, Calif.

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$3,900-\$4,500 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health, No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in cooperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Linck, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

The Department of Health, New Jersey, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual

opportunities for gaining experience in occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Physicians interested in these positions should write to the Department of Health, Trenton, N. J.

Merit System for Personnel Administration in Delaware will set examinations for 3 positions in the Delaware State Board of Health shortly. The positions open for examination, together with the beginning salaries, are: Deputy State (County) Health Officer (\$3,800), Pediatrician (\$3,600), and Medical Social Consultant (\$2,400).

These examinations will be unannounced, but successful candidates will be expected to appear in Delaware for an oral interview which will be a weighted part of the examination. Appointments may be expected soon after the examinations are conducted.

Information and specifications as prepared for each position may be secured by communication with the Merit System Supervisor, P. O. Box 1911, Wilmington, Del., and application for examination must be made on the official form.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5 per month each year until \$135 has been reached. To this basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus

maintenance. Apply to Dr. G. F. Burgardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Wanted: Public health statistician for large California County Health Department. College degree with training in statistics. Salary \$200. Position open. Address William C. Buss, M.D., Kern County Health Dept., Bakersfield, Calif.

Hawaiian Territorial Board of Health seeks trained engineer to supervise rodent plague control program. Salary range from \$331.67 to \$398.33 per month subject to retirement deductions plus bonus. Position under Territorial civil service system with classification of P-4. For further details address A.P.H.A. Employment Service.

Wanted: Physical therapist by crippled Children's Division. Should be graduate of a school of nursing or of college, with a major in physical education or science; have completed a course in physical therapy; should have had experience in physical therapy, preferably with children. Write for application blank to Merit System Council, 416 Henry Building, 309 S.W. 4th Ave., Portland 4, Oregon.

Psychiatric case worker desired for mental hygiene clinic, Department of Health, Peoria, Ill.

Senior Sanitarian, Alaska Health Department. Minimum requirements 2 years college, 6 months public health course, 2 years' experience. Two additional years' experience acceptable instead of each year college. Monthly salary \$235-\$265. Mary B. Pool, Alaska Merit System, Juneau.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK 19, N. Y.

In view of the current active demand for trained and experienced persons in public health, it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y., for up-to-date lists of applicants.

Woman physician, well prepared in pediatrics. M.S.P.H. DeLamar Institute, Columbia University 1943, seeks employment in field of maternal and child health, preferably administrative in pediatrics. Excellent references. **A-507**

Physician, M.D. University of Arkansas, M.P.H. Harvard, experienced as county health officer. Age 35. Will consider position as county or city health officer or director of a bureau. **A-506**

Physician, age 28, M.D. Yale, trained in pediatrics, now county health officer of southern state, seeks administrative position in northeastern United States. **A-509**

Woman physician, age 35, M.D. University of Minnesota, 2 years' experience as county health officer, seeks clinical or administrative position, preferably South. **A-510**

HEALTH EDUCATION

Woman with background of health education and public health nursing, experienced as teacher, supervisor, and writer, seeks teaching position of responsibility. **H-507**

LABORATORY

Research bacteriologist. Unusually trained and experienced woman bacteriologist and serologist now occupying responsible position in state laboratory seeks research work of permanent character. **L-468**

Water chemist, bacteriologist, M.S. degree in Sanitary Chemistry. Age 36, draft exempt. Eight years' experience in state laboratory working on water, milk and sewage. Prefers Midwest or Pacific Northwest location. **L-469**

NEWS FROM THE FIELD

RESOLUTIONS ADOPTED BY THE LATIN AMERICAN DELEGATES TO THE INTER-AMERICAN CONFERENCE ON HEALTH EDUCATION HELD AT THE TIME OF THE 72ND ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION IN NEW YORK CITY, OCTOBER 11, 1943.

I

The delegates attending the First Conference on Health Education hereby express their gratitude to the Pan American Sanitary Bureau in Washington and to the Institute of Inter-American Affairs for having sponsored this Meeting, which will mark an important step in the cooperative program for the improvement of health conditions in the Americas. The Delegates also wish to express their gratitude to the American Public Health Association for having included this Conference in its 72nd Annual Meeting.

II

The Conference on Health Education also passed a resolution commending all those persons in the countries of America who are working to create a general health consciousness among the inhabitants of the Western Hemisphere, urging them to coordinate their work for more effective results.

III

The Conference on Health Education, having been informed of the effective work being done by the Governments of the American countries in behalf of health education, adopted a special resolution to recommend that this work be based upon the modern technical methods which experience has demonstrated to be useful in this activity.

IV

The Conference on Health Education expressly declares that health education should be made an integral part of public education and that, consequently, the teachers should be properly instructed so that they can perform these duties. This instruction should be given in the Institutes and Health Schools already established, or in other appropriate institutions. It is also recommended that this matter be discussed at the forthcoming meeting of the Health Teachers of America to be held in Ann Arbor. The papers contributed by several delegates to the Conference are referred to said meeting of the Health Teachers of America for deliberation.

V

Since health education is fundamentally necessary for the effective progress of hygienic practices among the people, the Conference on Health Education recommends that an Inter-American Conference on this subject be held in one of the Latin American capitals; and in consequence, it requests the Pan American Sanitary Bureau and the Institute of Inter-American Affairs, in pursuance of their customary policy and with the assistance of the respective governments, to organize such a conference. The Conference on Health Education believes that in this manner the progress made in social security, and the affirmation of the principles set forth in the Atlantic Charter will be secured. Therefore, as the last act of its deliberations, it urges that this conference be organized and held.

NEW COURSE IN HEALTH EDUCATION FOR LATIN AMERICANS

Arrangements have been completed between the University of California and the Institute of Inter-American Affairs to establish a special course in Health Education to meet the particular requirements of students from Latin America. This course will begin on March 1, 1944. Students who require English instruction will be urged to come to this country not later than December 10, 1943, so that they may have time to secure the necessary instruction. The course in English will be specially planned to deal with the vocabulary which will be used in the later course in Health Education and will serve also as an orientation course. During the preliminary training period, it is expected that selected students may have an opportunity to attend other courses in the University which will assist them in later studies in Health Education.

The Health Education course will be given in the newly established School of Public Health, which is under the direction of Walter H. Brown, M.D., who has had a long experience in the United

States and abroad in public health administration and health education. It will include training in the principles of public health and hygiene, and in the principles of education, particularly as these apply to conditions in South and Central American countries and the health work of the C.I.A.A. in those areas. Arrangements are being made to appoint one or more experienced public health administrators from Latin America to serve temporarily on the faculty so that their experience will be available to assure that instruction is given in accordance with the needs arising out of the particular conditions in various countries.

All applicants must give evidence of their intention to undertake service in public health or in school health work in Latin America after completion of the course.

Classroom instruction will be given on the campus at Berkeley, Calif., after which there will be supervised field training. While in Berkeley, the students will be housed by the International House organization, which has had a long experience in assisting students from Latin America in making their stay in this country pleasant and profitable. In order to assure maximum value of instructional facilities, the class for 1944 will be limited to thirty students.

Applicants for study grants from the Institute of Inter-American Affairs should be between the ages of 30 and 45 years, although consideration will be given to applications from those outside this age group in exceptional circumstances. Individuals with prior training or experience in public health work, school health education, and related fields will be given preference in selection, but others may also apply. Applications will be received from both men and women. Candidates need not be physicians.

Students who are selected for this

training by the Institute of Inter-American Affairs will receive monthly stipends adequate to meet their living costs and will be furnished with tuition and transportation from their place of residence to the University of California, and return. Students should not bring their families with them. No funds or accommodations are available for this purpose.

All applications will be made through Chiefs of Party of the Coordinator's Office in each republic in accordance with regulations governing the Institute Training Program, or through the Pan American Sanitary Bureau, Washington, D. C.

TROPICAL MEDICINE AT COLUMBIA-
PRESBYTERIAN MEDICAL CENTER,
NEW YORK

Dr. Harold W. Brown, Dean of the School of Public Health of the University of North Carolina, has resigned, effective January 1, to assume the Professorship of Parasitology at Columbia University. This appointment marks the beginning of a new program in Tropical Medicine at the Columbia-Presbyterian Medical Center. Dr. Brown is the first member of a faculty for training and research in tropical diseases, which will function under the immediate direction of the DeLamar Institute of Public Health, a division of the Medical School. This program has been made possible by a grant from the Josiah Macy, Jr. Foundation.

U. S. AND AMERICAN REPUBLICS
EXCHANGE MEDICAL KNOWLEDGE

The Americas are exchanging medical knowledge as part of a great inter-American health and sanitation program, now under way in seventeen of the other American republics.

In this continental effort to control and reduce the ravages of malaria, tuberculosis, yaws, and other diseases, the United States is contributing technical

and financial assistance through the Institute of Inter-American Affairs, an agency of the Office of Inter-American Affairs.

Many doctors, sanitation engineers and other specialists of Latin America are coming to the United States to study in leading medical schools, for observation and training in public health activities and in special fields of health work.

In turn, United States doctors are finding new opportunities for first-hand study and practical experience in the projects evolving out of the inter-American program, particularly in the campaign against malaria and other tropical diseases.

More than one hundred doctors from Latin America have come to the United States for additional training. In the reversal of this exchange, some thirty United States doctors already have completed training in Central America, where extensive work is being carried on for control of malaria.

Dr. Eugene P. Campbell, of the health and sanitation division of the Institute of Inter-American Affairs, Washington, reports that medical men from the United States are enthusiastic about the training they are receiving in the republics to the south. Dr. Campbell is director of the United States missions assisting Costa Rica, El Salvador, Guatemala, Honduras, and Nicaragua in health and sanitation programs.

The training program was established by the Association of American Medical Colleges, with the financial support of the Markel Foundation in New York.

PAN AMERICAN DEMOGRAPHIC COMMITTEE

The first Pan American Demographic Congress which met during October in Mexico City resulted in the formation of a permanent Pan American Demographic Committee to correlate statistics and to study problems connected with immigration and the movement of popu-

lations, it was reported in the *New York Times*. The underlying purpose of the Congress was said to have been the formulation of a joint Latin American immigration policy to cope with the pressure of organized groups that are expected to ask the Western Hemisphere countries to open their doors to European immigrants after the war.

Lowell J. Reed, Ph.D., Dean of the School of Hygiene and Public Health of Johns Hopkins University, Baltimore, and Earl G. Harrison, United States Commissioner of Immigration and Naturalization, represented the United States. It was said that the results of the Congress were satisfactory and that they enabled the delegates of the 21 American republics to exchange information and experience.

UNIVERSITY OF BIRMINGHAM, ENGLAND, SEEKS PROFESSOR OF SOCIAL MEDICINE

Dr. George Auden, Birmingham, England, writing recently to Dr. Haven Emerson, describes a grant which the Nuffield Trust has made for a Chair of Social Medicine at the University of Birmingham, the salary at £1,500 may be raised to £2,000.

"I believe strongly that it is probable that a suitable holder of this important chair is more likely to be found on your side of the Atlantic. We have nothing to compare with the Johns Hopkins School of Hygiene in depth and width of training, for in England the teaching of hygiene in our medical schools has been mainly directed towards the Diploma in Public Health—a sine qua non for a public health appointment, and the training of our medical students has centered round the out-patient and in-patient departments of hospitals with little or no reference to the social factors of environment, temperament, etc., in relation to disease. The advertisements are now being published in our medical papers and applications need not be submitted (with three references) before the 1st of March, 1944. I hope you will let this be known amongst the medical schools. It might tempt some pioneer enthusiast. The chair offers such splendid opportunities and should be held by a man

of real originality and distinction if it is to be a real success. Unfortunately our clinical colleagues find it hard to see what is meant by 'social medicine.' They will tend to look for a clinician rather than for a bio-sociologist. Particulars can be obtained from the Secretary of the University, C. G. Burton, Edmund Street, Birmingham 3."

DR. SHOPE AWARDED JOHN SCOTT MEDAL

The award of the John Scott Medal to Dr. Richard E. Shope of the staff of the Rockefeller Institute for Medical Research, New York, N. Y., has been announced in recognition "of his discovery of the complex etiology of swine influenza."

RHEUMATIC FEVER REPORTABLE IN MARYLAND

By an action of the Maryland State Board of Health on September 23, rheumatic fever and rheumatic heart disease were made reportable, according to an announcement released by Robert H. Riley, M.D., the Director of the State Department of Health.

CHILDREN'S BUREAU CONFERENCE ON RHEUMATIC FEVER

A conference called by the Children's Bureau met in Washington early in October to discuss the problems related to rheumatic fever. About 100 persons attended who were told that special services for children with rheumatic fever are now financed through 13 official state agencies, with funds appropriated by the Children's Bureau for this purpose. More than 3,600 children had visited clinics for this purpose during the last year.

According to the press, Dr. Martha M. Eliot, Associate Chief of the Children's Bureau, spoke favorably of the use of the sulfonamide drugs in protecting children from recurrent attacks of rheumatic fever and prolonging their lives. According to Brigadier General Hugh J. Morgan, Consultant in Medicine, Office of the Surgeon General, U. S.

Army, only one-third of the service men who develop or have been discovered to have had rheumatic fever can be salvaged to the point where they can carry on effectively in the Army. He urged civilian health authorities "to follow the lead of the Army and Navy in steps to combat the disease."

TENNESSEE DIVISION OF VITAL STATISTICS COÖPERATES WITH LOCAL RATIONING BOARDS

A coöperative program for the exchange of certain information concerning births and deaths has been developed between the Tennessee Office of Price Administration and the Tennessee Department of Public Health. This program consists of furnishing to local War Price and Rationing Boards lists of births and deaths registered with local registrars of vital statistics. In turn, the local War Price and Rationing Boards furnish the local registrars with lists of persons whose ration books have been returned on account of death.

According to Don C. Peterson, M.D., State Registrar of Vital Statistics, this plan accomplishes the following purposes:

1. It prevents the fraudulent securing of ration books for infants.
2. Prevents the issuance of duplicate ration books for infants.
3. Assists local War Price and Rationing Boards in securing the surrender of ration books of persons who have died.
4. Promotes a more prompt and complete registration of all births and deaths in the State of Tennessee.
5. The local War Price and Rationing Boards receive through local registrars of vital statistics an official confirmation of births and deaths reported in their respective jurisdictions at regular intervals.

This plan has been in operation in Tennessee with satisfactory results since January 1, 1943. Apparently the success of the plan is due largely to the fact that all work is carried out at the local level with a minimum delay to the

public. Parents may secure ration books for the new baby in a matter of an hour or so, if desired, as all the necessary persons are in the immediate vicinity and are readily available. There are no fees involved and no additional requirements imposed on the public. Prior to the inauguration of this program, the local War Price and Rationing Boards had no source of information on deaths other than newspaper items or hearsay evidence. Consequently, a very small proportion of ration books of deceased persons were being surrendered. The program has very materially altered this situation and it is the impression that these books are now being surrendered promptly on receipt of a notice from the Board. The improvement in birth registration has been most marked. At the present time approximately 25 per cent more birth certificates are being filed than for the same period in previous years. Not all of this increase can be attributed to an increase in the actual number of births occurring in the state. In addition to improvement in birth registration, more complete information is becoming available concerning unreported deaths. This information is being used by the local registrars in improving death registration.

LABORATORY TRAINING FELLOWSHIPS

The W. K. Kellogg Foundation has granted ten fellowships to the Maryland State Department of Health for the training of qualified students in clinical and public health laboratory work, according to R. H. Riley, M.D., Director, Maryland State Department of Health. Training in clinical laboratory work will be at the Union Memorial Hospital School of Medical Technology or at the University of Maryland Hospital, both located in Baltimore. Training in public health laboratory methods will take place in the central laboratories of the Bureau of Bacteriology of

the State Department of Health. The entire course will cover a full 12 months of training. Only students who have completed their basic training at an accredited college or university, or those who will be eligible for a bachelor's degree upon satisfactory completion of this course, can be granted fellowships.

Fellows who satisfactorily complete this training course will be qualified in both public health and clinical laboratory work. In addition to their bachelor's degree, they will have had a year's experience along with their special training, so that they can meet the requirements for Junior Assistant or Senior Assistant Bacteriologists (or serologists) as recently prescribed by the American Public Health Association. They will also have absolved the qualifications for medical technologists as established by the American Society of Clinical Pathologists. Graduates will be qualified, therefore, to accept positions in public health or clinical laboratories and should be especially qualified for positions in medico-public health laboratories such as are developing in Maryland, where both types of training are essential.

NEW SCHOOL HEALTH SERVICE

DAILY-MONTHLY REPORT

The National Organization for Public Health Nursing, New York, N. Y., has released a new School Health Service Daily-Monthly Report Form after a trial period of four years. The report may be used by the nurse doing school work as a part of the generalized program, as well as by the specialized school nurse, and is designed to show both quality and scope of service.

UTAH PUBLIC HEALTH ASSOCIATION

The Utah Public Health Association met in Salt Lake City September 25 under the Presidency of William M. McKay, M.D., State Health Commissioner. The program items included

Industrial Hygiene of the Army, Army Borne Tropical Diseases, the problems of maternal morbidity and studies in poliomyelitis, among others.

New officers elected were as follows:

President for the ensuing year: H. L. Marshall, M.D.

President-elect, E. H. Bramhall.

Vice President, D. Keith Barnes, M.D.

Secretary, Elmer B. Quist.

Treasurer, Dorothy Lowman.

Directors, Verna Peterson and Howard M. Hurst.

Meeting jointly with the Utah Public Health Association were the Utah Public Health Nurses Association and the Utah Sanitarians Association.

SOUTH DAKOTA PUBLIC HEALTH ASSOCIATION

The South Dakota Public Health Association met in Huron on September 21 under the Presidency of G. L. Hickman, M.D. Gilbert Cottam, M.D., is the Secretary-Treasurer and Superintendent of the State Board of Health.

CHANGES IN OCD SANITARY ENGINEERING STAFF

George Baehr, M.D., Chief Medical Officer of the Office of Civilian Defense, Washington, D. C., has announced the following changes in the sanitary engineering staff of the Medical Division, Office of Civilian Defense.

LINDON J. MURPHY, who has been Director of Engineering Extension Service, Iowa State College, Ames, Ia., has been commissioned in the U. S. Public Health Service Reserve and assigned as Regional Sanitary Engineer in the 7th Region in Omaha, Neb.

WILLIAM T. INGRAM, who has been Assistant Regional Sanitary Engineer with headquarters in San Francisco, has been promoted to the position of Regional Sanitary Engineer, succeeding Gerald E. Arnold who has been assigned to the San Francisco district of the War Production Board. Mr. Ingram formerly was sanitary engineer of the San Joaquín

local health district, Stockton Calif. He received the M.P.H. degree from Johns Hopkins in 1942.

JOHN C. LUTHIN, recently on the staff of the Kaiser Company, Richmond, Calif., has been commissioned in the U. S. Public Health Service Reserve and assigned to succeed Mr. Ingram as Assistant Regional Sanitary Engineer in San Francisco.

HUGH R. MCCALL, Regional Sanitary Engineer with headquarters in Baltimore, has been transferred to the Central Office of the OCD in Washington as Assistant Chief Sanitary Engineer in the Medical Division.

Succeeding Mr. McCall, WARREN H. BOOKER, Director of the Division of Sanitary Engineering of the North Carolina State Board of Health for the last 12 years, has been commissioned in the Public Health Service Reserve and assigned to Baltimore.

AMOS J. ALTER, a member of the Central Office staff of the OCD for the past year, has been transferred to the office in Dallas, Tex., as Assistant Regional Sanitary Engineer.

LATIN AMERICAN VISITORS AT THE 72ND ANNUAL MEETING, A.P.H.A.

More than 70 visitors from Latin American countries attended the recent Annual Meeting of the American Public Health Association, many of them guests of the Pan American Sanitary Bureau and the Office of the Coördinator of Inter-American Affairs. Some currently are students in American universities. Included in the list were the following:

ARGENTINA: Dr. Luis M. Barreiro
Dr. Alfredo Sordelli
Dr. Alberto Zwanck

BOLIVIA: Dr. Felix Veintemillas
Dr. Carlos Ferrufino

BRAZIL: Dr. Jesuino Albuquerque
Dr. Paulo do Amaral-Pamplona
Dr. Olympio da Fonseca
Mr. Jose Franco-Henriques
Dr. Vasco de Freitas-Barcellos

Dr. Abelardo Marinho
 Dr. Egberto Prochat de Assis
 Dr. Orlando Rodrigues da Costa
 Mr. Marcello Teixeira-Brandao
 Dr. G. H. de Paula Souza
 Dr. Silvio de Sao Paulo

CHILE: Dr. Marcos Charnes
 Dr. Mario Pizzi
 Dr. Mario Prado-Lefort
 Dr. Francisco Rojas
 Dr. Hernan Romero

COLOMBIA: Mr. Prospero Ruiz

COSTA RICA: Dr. Fernando Guardia
 Dr. Julio C. Ovaes
 Mr. Rodrigo A. Vargass

CUBA: Dr. Moises Chediak
 Dr. Pedro Machada
 Mr. Raoul F. Cowley
 Dr. Guillermo Lage y Fernandez
 Dr. Felix Hurtado
 Dr. Domingo F. Ramos
 Dr. Alberto Recio

DOMINICAN REPUBLIC: Mr. Salvador Sanlley

ECUADOR: Mr. Cesar A. Ribadeneira
 Dr. J. A. Montalvan

EL SALVADOR: Dr. Alberto Aguilar-Rivas
 Mr. Francisco Sequeira
 Mr. Roberto Vargas

GUATEMALA: Dr. Enrique Padilla
 Mr. Julio Montano
 Dr. Epaminondas Quintana

HONDURAS: Mr. Jorge E. Zepeda

MEXICO: Dr. Salvador Acosta-Baylon
 Dr. Joaquin Alvarez de la Cadena
 Dr. M. A. Alarcon
 Dr. Alfonso Alarcon-O'Farrill
 Dr. Amado Alarcon-O'Farrill
 Dr. Luis de Alba-Luva
 Dr. Luis Benitez-Soto
 Dr. Salvador Gonzalez-Reynoso
 Dr. Victor Ocampo-Alonzo
 Dr. Federico Ortiz
 Dr. Alfonso Segura-Albiter
 Dr. Salvador Iturbide-Alvarez
 Dr. Miguel E. Bustamante
 Dr. Mario Quinones
 Dr. Gustavo Uruchurtu

NICARAGUA: Dr. Carlos Amaya
 Dr. Arturo Rodriguez R
 Dr. Manuel A. Sanchez-Vigil

PANAMA: Dr. Benigno Angulo
 Dr. A. Gonzalez-Revilla

PARAGUAY: Dr. Justino Almiron
 Dr. Arturo Jose Buzarquis
 Dr. Cesar Enrique Guggiari

Dr. Mariano Antonio Molas
 Dr. Raul Pena

PERU: Dr. Gregorio B. Hernandez
 Miss Elsa Paredes
 Dr. Carlos E. Paz-Soldan

URUGUAY: Dr. Estenio Hormaeche
 Dr. Federico J. Salveraglio

VENEZUELA: Mr. Enrique Gonzales-Navas
 Dr. A. Lares-Gabaldon
 Dr. Francisco Scannone
 Dr. A. L. Briceno-Rossi

Among this group are the members of the faculty of six schools of public health who are conferring with faculties of public health in the United States and Canada under a plan worked out by the University of Michigan and the W. K. Kellogg Foundation. It is expected that an arrangement for the interchange of students between countries in the American hemisphere will be developed. Members of this group include: Alberto Zwanck, Professor of Hygiene at the University of Buenos Aires; G. H. de Paula Souza, Professor of Public Health at the University of Sao Paulo, Brazil; Carlos Enrique Paz-Soldan, Professor of Hygiene at the University of San Marcos, Lima, Peru; Federico J. Salveraglio, Professor of Hygiene at the Medical School, Montevideo, Uruguay; Mario Prado-Lefort, Vice-director of the Institute of Bacteriology, Santiago, Chile; and Hernan Romero, Professor of Preventive Medicine and Public Health at the University of Chile, Santiago.

DR. GRAYSON RESIGNS AS ARKANSAS STATE HEALTH OFFICER

William B. Grayson, M.D., who since 1933 has been State Health Officer in the Arkansas State Board of Health, has resigned, effective November 15, to enter private practice in Little Rock.

Dr. Grayson is succeeded by Thomas T. Ross, M.D., M.P.H., as Acting State Health Officer, who for seven years has been connected with the Arkansas State Board of Health as

Director of Maternal and Child Health. Dr. Ross is a native of Arkansas, a graduate in 1928 of the Tulane University School of Medicine, with a Master's degree in public health from Harvard School of Public Health in 1934.

WILLINK BECOMES BRITISH MINISTER OF HEALTH

The press on November 11 announced the appointment of Mr. H. U. Willink as Minister of Health of Great Britain, replacing Mr. Ernest Brown who now becomes Chancellor of the Duchy of Lancaster. According to the reports, Mr. Willink was in charge of the homeless in London during the blitz.

According to the *New York Times*, Mr. Willink will have a great deal to do with plans for rebuilding Britain, one-fifth of whose houses are said by the government to have been damaged since the start of the war.

In the same series of changes, Lord Woolton, who has been Minister of Food in Great Britain, has been appointed Britain's first Minister of Reconstruction, with a place of authority in the War Cabinet.

ILLINOIS UNDERTAKES SCHOOL HEALTH STUDY

Roland R. Cross, M.D., State Director of Public Health, Springfield, Ill., has announced plans for "the development of more effective, continuous, and coordinated public health programs in the schools." A joint committee has been set up representative of health and educational authorities, and a comprehensive study is planned of the existing assets and liabilities in the present school health programs throughout the state.

It was announced early in November that Clair E. Turner, Dr.P.H., Professor of Public Health at the Massachusetts Institute of Technology, Boston, would direct the study. The

project was linked with the movement in Illinois for the establishment of home-rule county health departments by the *Illinois Health Messenger*, as well as with the work of the State-wide Committee on Public Health which was organized following the survey of Illinois made under the auspices of the Committee on Administrative Practice of the A.P.H.A. by Dr. Carl E. Buck, Field Director.

SCHOLARSHIPS IN NURSE EDUCATION AVAILABLE

Lucile Petry, Director of the Division of Nurse Education of the U. S. Public Health Service, has announced that the increased enrollment of student nurses resulting from the recruitment program of the U. S. Cadet Nurse Corps has intensified the need for qualified instructors in the country's schools of nursing. All-expense scholarships in nurse education have been made available under the Bolton Act to encourage postgraduate training for nursing school graduates who show a particular aptitude for teaching. Schools of nursing have been urged to select members from their graduating classes who show promise as instructors. These graduates have been encouraged to apply to colleges and universities offering the desired type of postgraduate nurse education. A list of the colleges and universities offering postgraduate study and details of the study programs offered by each may be obtained from the Division of Nurse Education, U. S. Public Health Service, Washington, D. C.

WOMEN SANITARIANS IN TEXAS

The *Texas Journal of Public Health* for September-October reports that the Department of Public Health and Welfare of the City of Fort Worth has employed three women sanitarians for a temporary period. Their work, it is said, has resulted in improving sub-

stantially the sanitation of food handling establishments, particularly in the business district.

VISITORS FROM ECUADOR

Among recent visitors to this country were Dr. Leopoldo Izquieta Perez of Guayaquil, the Director of Health of Ecuador, and Dr. Cornelio Donoso, the Director of the Municipal Health Department of Quito, Ecuador.

CHANGES IN STAFF OF THE MEDICAL DIVISION, OFFICE OF CIVILIAN DEFENSE

DR. COURTNEY M. SMITH,* Assistant Regional Medical Officer in the Ninth Civilian Defense Region, recently stationed in Seattle, Wash., has been promoted to be Regional Medical Officer with headquarters in San Francisco. He succeeds Dr. FRED T. FOARD,* Senior Surgeon, U. S. Public Health Service, who has been made District Director, U. S. Public Health Service District No. 8, with headquarters in Denver. Prior to his appointment in the Medical Division of the Office of Civilian Defense, Dr. Smith was Assistant Health Commissioner of Alaska. He holds the rank of Surgeon in the U. S. Public Health Service Reserve.

DR. ARTHUR J. LOMAS, Deputy State Chief of Emergency Medical Service for Maryland, has been assigned as Regional Medical Officer for the Third Civilian Defense Region, which includes Maryland, Pennsylvania, and Virginia. Headquarters are in Baltimore. Dr. Lomas, who formerly practised medicine at Lutherville, Md., succeeds Dr. MARK V. ZIEGLER,† Senior Surgeon, U. S. Public Health Service, who has been assigned to the U. S. Maritime Commission. Dr. Lomas has the rank of Surgeon in the U. S. Public Health Service Reserve.

DR. BENJAMIN MILLER, Assistant Professor of Medicine, University of

Chicago School of Medicine, Chicago, was recently commissioned in the U. S. Public Health Service and assigned to the Washington staff of the Medical Division October 1, as Assistant Chief of the Scientific Research and Development Section.

LOUIS G. GOETZ, who came to the Medical Division as equipment officer in March, 1943, has entered military service. Before joining the Medical Division staff, Mr. Goetz was Assistant Comptroller at St. Luke's Hospital, New York, N. Y.

DR. WARD L. MOULD, Surgeon, USPHS, who has been assigned to the staff of the Medical Division, Office of Civilian Defense, since September, 1941, has returned to the U. S. Public Health Service. Dr. Mould served in various capacities in the Medical Division, most recently as medical chief of the industrial plant unit. He has been assigned temporarily as Assistant to the Director, U. S. Public Health District No. 1, with headquarters in New York, N. Y.

DR. VICTOR H. VOGEL, Surgeon, USPHS,† Administrative Officer of the Blood Plasma Unit of the Medical Division since its establishment early in 1942, has been transferred to the staff of the U. S. Public Health Service Hospital in Lexington, Ky.

PERSONALS

Central States

LEON H. FLANCHER, M.D., Epidemiologist, Division of Preventable Diseases (Tuberculosis Control), Minnesota Department of Health, has been appointed Director of the Division of Tuberculosis Control of the Iowa State Department of Health.

CHARLES F. MCKHANN, JR., M.D.,* has resigned from the faculty of the University of Michigan School of

* Fellow A.P.H.A.

† Member A.P.H.A.

Public Health, where he was Professor of Maternal and Child Health, to accept an appointment as assistant to the President of Parke, Davis & Company, Detroit.

LAURENCE T. ROGERS has been appointed Assistant Secretary of the Health Division of the Chicago Council of Social Agencies, Chicago, Ill.

CONRAD S. SOMMER, M.D., Chief Medical Officer in the Department of Public Welfare of Illinois, has been named Deputy Director of the Mental Hygiene Service, a newly created position. He is to supervise the twelve mental hospitals, the Neuropsychiatric Institute, the Division of Veteran Service and the Bureau of Home Economics and Nutrition.

HOLLAND THOMPSON, M.D., of Montgomery, Ala., Director of Tuberculosis Control for the State of Alabama, has been named Director of a new Tuberculosis Control Division, recently established by the Indiana State Board of Health to coördinate the work in the state against tuberculosis. At present all tuberculosis control activities of the State Board of Health are administered by the Communicable Disease Division.

Eastern States

MARY M. ATCHISON, M.D., M.P.H.,† formerly Director of the Divisions of Maternal and Child Health and Crippled Children's Services, New Hampshire State Board of Health, Concord, N. H., and recently Acting Deputy Secretary of the State Board, has been appointed Acting State Health Officer. Dr. Atchison fills the vacancy that occurred when ALFRED L. FRECHETTE, M.D., M.P.H.,† was granted a leave of absence as Secretary of the Board to engage in war

rehabilitation work under the auspices of the U. S. Public Health Service.

MURIEL F. BLISS, PH.D.,* Hartford, Conn., has resigned from the staff of the Connecticut State Department of Health to become Executive Secretary of the Hartford Tuberculosis and Public Health Society, effective November 1. Dr. Bliss, who received her degree in public health from Yale in 1943, was formerly connected with the Cancer Committee of Nassau County, Long Island, N. Y.

DR. A. JOSEPH HUGHES, of Camden, N. J., has been named by the State Board of Health as Medical Assistant to State Health Director J. LYNN MAHAFFEY, M.D.,† to develop a preventable disease program.

ALFRED E. KESSLER,† Director of the Buffalo Junior Chamber of Commerce, Buffalo, N. Y., has been appointed Chairman of the U. S. Junior Chamber Public Health Committee. Mr. Kessler is Health Education Secretary of the Buffalo and Erie County Tuberculosis Association.

WILLIAM E. MOSHER, JR., M.D.,† of Cortland, N. Y., has resigned as Health Commissioner of Cortland County to enter the armed services. M. W. YALE, PH.D.,† formerly with the New York State Agricultural Experiment Station in Geneva, N. Y., is now Bacteriologist with the Shefford Cheese Company in Green Bay, Wis.

Southern States

RICHARD E. BANNER, M.D., of Kansas City, Mo., has been named head of the Health Unit in Johnson County, with headquarters at Warrensburg, Mo.

DOROTHY DAVIS BRYAN, of Nashville, Tenn., has been appointed to succeed the late HALE E. CULLOM, M.D., as Director of Sight Conservation and Prevention of Blindness for the State of Tennessee.

* Fellow A.P.H.A.

† Member A.P.H.A.

TILMAN E. DODD, M.D.,† of Bryan, Tex., has resigned as Health Officer of the Bryan-Brazos County Health Unit.

ROBERT H. HUTCHESON, M.D., C.P.H.,* of Nashville, Tenn., Assistant Commissioner and one time Superintendent of the Williamson County Health Unit, has been appointed State Commissioner of Public Health. He succeeds WILSON C. WILLIAMS, M.D., C.P.H.,* of Nashville, who accepted a commission as lieutenant colonel in the Medical Corps of the Army and who has been ordered to active duty.

ESTELLA LUCILLE JOHNSON MARSH, M.D., of Tallahassee, Fla., has been appointed Director of the Bureau of Maternal and Child Health of the Florida State Board of Health. Dr. Marsh has been serving as Chief Physician at the Florida State College for Women, Tallahassee. Since the resignation of ROBERT C. HOOD, M.D.,† of Jacksonville, to enter private practice in Arlington, Va., in 1942, the Bureau of Maternal and Child Health has been in charge of ERWIN F. HOFFMAN, M.S.P.H.,† Director of the Bureau of Epidemiology.

RITA MILLER has been appointed Consultant on Negro Nurse Education in the Division of Nurse Education, U. S. Public Health Service, Washington, D. C. Miss Miller is on loan from Dillard University, New Orleans, La., where she is Chairman of the Division of Nursing.

BENTON M. MONTGOMERY, M.D., has been named Director of the Clarendon County Health Department, succeeding EDWARD ALEX HEISE, M.D.,† who is now in charge of the Sumter County and City Health Departments. Dr. Montgomery is also Director of the Williamsburg County Health Department.

LUTHER A. RISER, M.D., of Sedgfield, N. C., has been named Director of

the Bureau of Vital Statistics of the South Carolina State Board of Health, to succeed MARTIN B. WOODWARD, M.D.,† of Aiken, who resigned to accept a similar position in West Virginia.

JOHN SCHREIBER, M.D.,† of San Augustine, Tex., has been named Health Officer of Nolan County.

ELMER J. TEAGARDEN, M.D., of Orlando, Fla., has been appointed Director of the Florida State Board of Health's Bureau of Tuberculosis. Dr. Teagarden has been serving as Superintendent of the Morgan County Tuberculosis Sanatorium, Flint (Decatur P. O.), Ala., and succeeds LYNNE E. BAKER, M.D.,† of Jacksonville, who resigned to enter private practice in Dayton, Ohio, last July.

RUSSELL M. WILDER, M.D., Chief of the Civilian Food Requirements Branch of the Food Distribution Administration, Washington, D. C., has resigned. Dr. Wilder will return to his work at the Mayo Clinic, Rochester, Minn., but will serve as medical adviser to the administration.

CAMILLA LOUISE WILLS,† of Towson, Md., was appointed to join the faculty of Lander College, Greenwood, S. C., to teach and be head of the Biology Department.

THOMAS V. WOODRING, M.D., Assistant Health Officer of Nashville, Tenn., for more than 15 years, has been appointed Director of Health of Nashville, a position recently created under a revision of the charter for the city. JOHN OVERTON, M.D.,† will continue as City Health Officer.

KENNETH J. WULFERT,† of Clayton, Mo., Assistant Public Health Engineer of the St. Louis County Health Department, has been commissioned a Second Lieutenant in the U. S. Army Sanitary Corps and has

American Journal of Public Health

and THE NATION'S HEALTH

Index of Volume 33, 1943

How to Use the INDEX

This is an Index to all the reading matter in the JOURNAL. It is essentially a title and author Index, although occasional subject headings are provided.

Articles, committee reports, and editorials are listed alphabetically according to the key words in the title, with many cross-references.

Editorials are indexed under "Editorials" as well as alphabetically under the key words in the title.

News notes and fillers are indexed under "News from the Field." This section should be searched as supplemental to the title index.

Matters pertaining to the Association are indexed under "American Public Health Association."

Book reviews are indexed under "Books and Reports."

Obituaries are indexed under "Death Notices."
